Yet we cannot attribute the entire Cretaceous extinction to a gradually deteriorating climate. Something more dramatic must have happened, as the plankton line testifies. Perhaps this dramatic cause gained greatly in effect because more groups than usual were in decline and therefore susceptible to a *coup de grâce*. In this sense, any complete theory of the Cretaceous extinction will be a complex combination of a dramatic end superimposed upon a general deterioration. On the other hand, a fair percentage of groups are always in decline, and catastrophes will always administer the *coup de grâce* to something. Extinction is no shame, but rather the ultimate fate of all major groups; dinosaurs and ammonites had done better than most.

In any case, geologic evidence constrains us to look for a cause that is worldwide in effect, able to exterminate groups in all major habitats, and geologically sudden for at least some of its results. Which brings me back to asteroids.

The asteroidal theory, like so many interesting hypotheses in science, had its root in a study with markedly different aims (you cannot actively look for the utterly unexpected). A team headed by Luis and Walter Alvarez at Berkeley, California, thought that they might use the amount of iridium in sediments as an indicator of their depositional rate. Iridium, a rare metallic element of the platinum group, is one to ten thousand times more abundant in asteroids and meteorites than in the earth's crust and upper mantle. (Since both the earth and meteorites congealed from the same source, we must assume that the earth as a whole contains as high a percentage of iridium as the meteorites.) But the earth melted and differentiated, and such heavy, unreactive elements as iridium sank into the inaccessible central core. The smaller bodies that form meteorites and asteroids never differentiated and therefore maintain iridium in its primeval abundance. Hence, most iridium in the earth's sediments comes from extraterrestrial sources. Working with the common assumption that meteorites and cosmic dust intrude on the earth as a fairly constant rain, the Alvarezes reasoned that sediments high in iridium must have formed slowly since relatively less earth-based debris had accumulated to dilute the cosmic influx.

But the Alvarezes were not prepared for the anomalously high concentrations of iridium that they found in two places: in the Umbrian Apennines of Italy and near Copenhagen. Iridium levels were 30 times higher than average in Italy and 160 times higher in Denmark. Moreover, an analysis of twenty-seven other elements in the Italian sample showed that none departed by more than a factor of 2 from "average behavior" in ordinary sediments. The anomaly involves iridium alone.

The Alvarezes wondered if they could apply the style of explanation they had originally favored: could sedimentation have been slow enough in these two places to yield such a high concentration of iridium from the normal cosmic rain alone. But they could find no evidence or even think of any reason for believing that these sediments had formed during a virtual shut-off of normal, depositional processes in the ocean. Instead, they were forced to reverse their perspective: sedimentation had been more or less normal; the iridium represented a genuine cosmic influx of unusual amount, not an undiluted gentle rain. The Alvarezes had another outstandingly good reason to favor such a reversal. Both samples came from thin clays deposited at the very top of the Cretaceous—coincident with the great extinction.

But what extraterrestrial source might both have produced the iridium and acted as a cause of the great extinction. The Alvarezes looked first to that venerable old standby of cosmic theories—the supernova that exploded near the earth and zapped our planet with so much cosmic radiation that many creatures mutated themselves out of existence. Yet, after flirting with the idea (partly in public) for a while, they dropped it—to my great delight, for it has never made any biological sense to me, despite its almost knee-jerk popularity in the "disaster literature." Radiation increases the mutation rate and yields a population with more variation. But more variation per se leads neither to extinction by prevalence of monstrosities nor to unusually rapid rates of evolution, because evolutionary tempos seem to be controlled by a different force—natural selection. Ordinary populations possess enough variation (without external goosing) to permit evolutionary rates so rapid that they appear instantaneous in geologic perspective. Mutation rates so high that they kill animals directly (not through the passage of defective genes to offspring) require supernovae too close to our sun to be plausible, given the spacing of stars in our part of the galaxy.

The Alvarezes now cite three reasons for rejecting a supernova:

1. A supernova would also have produced a high concentration of an ion of plutonium ($^{244}$Pu), yet the Italian and Danish clays contain levels of this ion ten times below the predicted value for a supernova..
2. Iridium occurs as two common isotopes ($^{191}$Ir and $^{193}$Ir). Since all the objects of our solar system had a common origin, the ratio of these two isotopes should be the same in meteorites and in the small amount of iridium indigenous to the earth's crust. Iridium formed in other stars might exhibit a different ratio. The ratio in the anomalous Italian and Danish samples matches that of the earth's indigenous iridium and probably came from our solar system.
3. In order to zap the earth with as much iridium as the Italian and Danish samples contain, the exploding star would have to be so close to our sun that the probability of such an event becomes too small to be believed.

Since the ratio of iridium ions led the Alvarezes to seek a source within our own solar system, they turned to objects that might hit the earth with reasonable probability and do sufficient damage. Most asteroids orbit the sun in the large space between Mars and Jupiter, but a few have more erratic orbits, and some, called Apollo objects, cross the earth's orbit in their wanderings. Since the asteroid Apollo was discovered in 1933, twenty-seven others that cross the earth's orbit have been

DISCOVER THE COAST OF INDIA AND THE WORLD'S BEST TRAVEL VALUES.

This is India. Near Madras, a modern resort in harmony with an ancient temple. Like her shoreline and the sea, India is unchanged and ever-changing. Living simultaneously in several centuries. The exquisite paintings and carvings of Ajanta and Ellora. The futuristic city of Chandigarh. Modern express trains and jetplanes. Hand pulled carts and elephant taxis. A land of variety and contrasts. Lush jungles. The snow-capped Himalayas. Balmy beaches and the crystal clear lakes of Kashmir. India is an enriching experience you can only find here. The people of the world's largest democracy will welcome you in your own language. And, in a recent article comparing travel costs in 12 countries worldwide, *Money Magazine* rates India first in value. So see your Travel Agent or mail this coupon today. Three oceans, 5000 years of history and warm, friendly people await you.

**INDIA LEAVES YOU RICHER**

I'd like to be enriched by India.

sighted. Astronomers discover an average of four more each year, while two independent estimates yield about 700 for the probable number of Apollo asteroids more than six-tenths of a mile (one kilometer) in diameter. The Alvarezes conclude that occasional collisions between Apollo asteroids and the earth are inevitable.

In short, their current scenario for the Cretaceous extinction calls upon the impact of an Apollo asteroid approximately six miles in diameter. They calculate that such an object would have produced a crater about 100 miles in diameter and injected enough dust into the atmosphere both from its own pulverization and by dismemberment of the earth around it to have made our entire planet as dark as Egypt during Pharaoh's ordeal. Photosynthesis might have been completely suppressed for a decade or so, leading to immediate death of the photosynthetic plankton (with their short generation time measured in weeks) and a subsequent collapse of the oceanic food chain based upon them. Most species of large terrestrial plants might have survived through the dormancy of their seeds, but the parental plants themselves would have died and taken their dinosaur herbivores with them. The Alvarezes calculate that Apollo asteroids of this size could have hit the earth with sufficient frequency to cause the six or so major extinctions that have punctuated the history of life since the inception of an adequate fossil record some 600 million years ago.

This scenario is not devoid of major problems. I am most disturbed by the special pleading required to make the pattern of extinctions come out right. I can buy the oceanic argument, but balk at the Alvarezes' attempt to explain why three terrestrial groups got through the great darkness relatively unscathed: plants, small vertebrates (mammals and birds), and nearshore vertebrates. In a classic case of eating and having their cake, they permit mammals to survive by eating seeds, yet call upon those very seeds to save the plant species that engendered them. Their explanation for nearshore vertebrates is grounded more in hope than in logic: survival "may be due to their ability to utilize food chains based on nutrients derived from decaying land plants carried by rivers to the shallow seas."

The Alvarezes are also suffering from too much of a good thing, for levels of iridium in the Danish sample are embarrassingly high. They calculate that average asteroidal iridium mixed with about 100 times its mass of earth material (the amount needed to conjure up the great dust cloud) should increase mean iridium levels in sediments by only about one-tenth the Danish amount. The Italian sample runs closer to expectations.

Other problems may be in store. One uncertain study argues, from the fine stratigraphy of magnetic reversals, that the plankton line is not coincident with dinosaur extinctions—a small effect for the more leisurely concept of geologic suddenness (which might span many thousand years), but potentially fatal to the Alvarezes requirement for true simultaneity. I feel that the Alvarezes assume the proper attitude toward this report: they acknowledge it forthrightly, note its uncertainties, admit that its later confirmation would greatly weaken or destroy their hypothesis, and then predict—on the basis of their theory—that the report is both probably in error and greatly in need of more study.

But I care little whether the asteroidal scenario itself is correct. The remarkable aspect of the Alvarezes' work—the part that has produced buzzing excitement among all my colleagues, rather than the ho-hum that generally accompanies yet another vain speculation—lies in their raw data on enhanced iridium at the very top of the Cretaceous in two separated places. For the first time we now have the hope (indeed the expectation) that evidence for extraterrestrial causes of mass extinction might exist in the geologic record. The old paradox that we must root against such plausible theories because we know no way to obtain evidence for them has disappeared.

When I started my career as a paleontologist, I used to argue that mass extinctions might be rip-roaring fun to discuss but relatively unimportant for the ultimate disposition of life and its history. I was then caught up in some common prejudices about inherent, stately progress as a hallmark of life's history. The mass extinctions, I thought, might disrupt the process severely, setting the clock of progress far back. But time (to a geologist) is not a severe constraint;

life would recover, moving on (and past) as before.

I can't think of any other idea I once held (after age five) that I now regard as so foolish (except the thought that the N.Y. Giants might catch the Brooklyn Dodgers in 1951, which they did—thanks again, Bobby Thomson). The history of life has some weak empirical tendencies, but it is not going anywhere intrinsically. Mass extinctions do not simply reset the clock; they create the pattern. They wipe out groups that might have prevailed for countless millenniums to come and create ecological opportunities for others that might never have gained a footing. And they do their damage largely without regard to perfection of adaptation (the most gorgeously designed photosynthetic plankter could not survive a great darkness, while some marginal competitor might squeak through and become a progenitor of the next dominant group).

Who knows? Without the great Cretaceous extinction, dinosaurs might have rallied and still dominate the earth (they had already lived for far longer than the sixty-five million years since their demise). Mammals might still be a small group of ratlike creatures casting about for an occasional bit of protein in a triceratopsian egg.

Among the Cretaceous mammals that witnessed the great event, we know a single primate named *Purgatorius*. It may not have been the only member of our order, but there probably weren't many of us back then. Suppose that *Purgatorius* hadn't pulled through—and remember, it probably owed its continuation to luck or to adaptations not related to features we value in primates because we have capitalized upon them. Primates would not have reevolved. A giraffe on the plains might now be surveying the creation from on high and smugly regarding itself as the finest of all God's creatures. Our current existence is an extended function of such enormous improbabilities. We may owe our evolution, in large part, to the great Cretaceous dying that cleared a path, yet permitted our ancestor's life to tread upon it. That asteroid may well have been the sine qua non of our existence.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

# This is what lasers cut best.

Costs – manufacturing costs.

Western Electric has many lasers at work.

And all are focused on one objective: helping the Bell System bring you the best possible telecommunications service at the lowest possible cost.

## Lighting the way

Western Electric gave the laser its first application in industry. In 1965, scientists at our Engineering Research Center designed a laser operation that vaporized holes through the diamonds used as dies for drawing copper wire. It turned a five-day drilling job into a 90-second flash.

It may sound simple, but it wasn't. There's much more to working a laser than "ready... aim... fire". Years of exhaustive research preceded that first laser-drilled diamond.

Every kind of laser reacts differently with different materials. A material that's transparent to natural light may be opaque to laser light, and vice versa. A laser that burns through one substance may have absolutely no effect on another.

Making *any* laser an industrial tool requires a host of experiments to determine not only which laser is best for the job, but how best to adapt it to the production process.

## Spectrum of questions

Complex questions of physics, chemistry, metallurgy, electronics and mechanical engineering must be answered and coordinated.

That's why there's a full-time laser studies group at our Engineering Research Center. It's the reason that Western Electric now uses lasers not only in drilling, but also in many other operations.

And these lasers are paying off – with better products manufactured for the Bell System at lower costs.

## Light of the future

Even with these uses, Western Electric has only begun to tap the laser's potential for telecommunications.

More applications are on the way. And they will bring more savings, more and better products made with laser technology.

Using lasers to cut costs is just one innovation from the Engineering Research Center. The Center's research in manufacturing techniques is an important part of Western Electric's total commitment to using the latest and the best in technology to keep the cost of your phone service down.

*Keeping your communications system the best in the world.*

# The Pocket Gopher Mound Probe

*Their architecture riddles the landscape, but the builders rarely come into view*

**by David S. Lee**

**photographs by Raymond A. Mendez**

People who live in pocket gopher country know well the conspicuous mounds of sandy soil made by the underground rodent. But few have ever seen the little animal, for the pocket gopher spends practically its entire life in a self-constructed burrow system, rarely venturing aboveground.

I was reminded of the pocket gopher's low public profile one summer while trapping research specimens near Gainesville, Florida. Curious about my digging activities, people would sometimes gather, and when told the object of my search, they were eager to see the subterranean animal. The usual comment was that even though they had seen the mounds for most of their lives, they had never seen the animal that made them. Most onlookers, surprised at the gopher's appearance, remarked that it resembled a rat. Indeed, its appearance must startle people who for generations have called pocket gophers "salamanders," and who likely conjured up an interesting bestiary in their attempts to visualize them.

The origin of the name salamander as applied to the pocket gopher is not clear. One possibility is that it is a corruption of "sandy-mounder," a name derived from the telltale piles of soil displaced from the animal's burrow system. Salamander is apparently reserved for the southeastern pocket gopher, *Geomys pinetis*, since its western counterparts are simply called gophers. In the Southeast, however, the name gopher is usually reserved for a reptile—the gopher tortoise. These tortoises also make burrows in the ground, and they frequent the same habitat, within a similar geographical range, as the pocket gopher. The need to distinguish these two animals may have resulted in the regional name salamander.

The southeastern pocket gopher is physiologically and behaviorally tied to a narrow association of fire-maintained xeric plant communities. The association with fire is another possible origin of the name salamander, which means "fire animal," for after a ground fire, the mounds of soil are not only more conspicuous but often more numerous. Thus, the local name could have the same derivation as that of the fire-loving salamanders of European folklore.

Pocket gophers are found throughout much of the southern United States and Central America, where more than 300 forms have been described. They achieve their greatest diversity in the southwestern United States; a smaller number of species and subspecies are known from areas of the West Coast, the Midwest, and the Southeast. All pocket gophers are medium-sized rodents (6.5 to 8 inches in body length) with fur-lined cheek pouches in which they carry food. These external pouches, or pockets, extend from beside the mouth down along the sides of the neck. The animal's large, exposed incisors are used as picks in burrowing. Dirt and sand do not get into the mouth, however, because the lips close behind the front teeth. The body is thickset and strong; the skin very loose and covered with short, soft hair. Although generally rodentlike in appearance, a pocket gopher looks strikingly out of proportion because of its enlarged head, shoulders, front legs, and claws. Its ears and eyes, on the other hand, are disproportionately small.

One of the most interesting aspects of the natural history of pocket gophers is their adaptation to an underground life style. Although the southeastern pocket gopher uses a resource (roots and rhizomes) not shared with any other local vertebrate, lives in a self-contained world of moderated temperature, and is fairly free of predators, the adaptations needed for a subterranean life are many. A low metabolic rate and the ability to obtain moisture from plant material enable gophers to compensate for a lack of free water in their burrow environment. Marked seasonal changes in food storage behavior, burrowing activity, and metabolic rate help gophers cope with annual fluctuations in temperature and food availability. Even superficial inventories of fresh mounds indicate considerable variations in seasonal activity, with the greatest number of new mounds appearing in the spring and the fewest during prolonged dry or cold periods in summer, fall, and winter.

Because the sealed tunnel system limits air exchange with the surface, pocket gophers must also be adapted to living in an atmosphere low in oxy-

*Large shoulders, front legs, and claws are adaptations for burrowing that enable the southeastern pocket gopher to construct extensive tunnel systems. Its eyes and ears are relatively small.*

*The digging activity of gophers has a strong effect on soil composition. Noncapillary porosity, organic matter, phosphorus, and nitrogen are higher in areas where the rodents are present.*

gen and high in carbon dioxide. Studies done by Perran Ross when he was a student at the University of Florida show a marked tolerance to high concentrations of carbon dioxide in this species. Ross also concluded that lower metabolic rates help limit oxygen requirements of pocket gophers and reduce their respiratory water loss. The high relative humidity of their closed environment may make regulation of body temperature by evaporative cooling a problem; perhaps their naked tail and feet aid in the dissipation of excess body heat.

The closed burrow system provides effective protection from predators, and pocket gophers have a relatively low mortality rate. This situation is balanced by an equally low reproductive rate. Studies suggest that southeastern pocket gopher males are sexually active all year and that females have at least two annual peaks of reproductive activity; yet more than 90 percent of all animals trapped were adults or subadults. The young of the year made up less than 10 percent of the sample. Embryo counts averaged only 1.5 per pregnant female. Such limited reproductive potential, while unusual for a small rodent, is not so surprising when one considers the pocket gopher's low vulnerability to predation.

With such a solitary life style within a self-contained burrow system, how does one pocket gopher find another of the opposite sex in order to mate? It is possible that males spend some time aboveground in search of females, and they may locate females in estrus by odor. Exposure to predators might account for a decrease in the percentage of adult males in the population (40 percent) compared with the percentage of males in the juvenile population (50 percent). Nevertheless, most searching takes place below ground. Males habitually construct long, straight tunnels, which greatly increase their chances of encountering the randomly directed burrows of females. On trapping expeditions I have occasionally used this bit of knowledge to wager with unsuspecting students as to the gender of the occupant of a particular burrow. One romantic male we encountered had tunneled in a perfectly straight line for more than 150 yards. When we captured him he was at the front line extending his tunnel. After mating, the males and females block off their tunnels to each other.

Due to the conspicuous mounds, the geographical and ecological distributions of pocket gophers can be easily studied. Mound inventories along road shoulders and other open habitats are readily made from a car. Thus, large tracts can be surveyed intensively and in a short time, with roads serving as convenient transects. By recording locations of colonies on county road maps, I was able to compare them with detailed regional soil and vegetation maps. In areas that have not been modified by man, I found that southeastern pocket gophers occur most frequently in upland scrub and sandhill plant communities that are maintained in a subclimax stage of ecological succession. In most cases fire caused by electrical storms serves as the policing agent, preventing dense understories of vegetation from becoming established. When fire is an almost annual occurrence, only the herbaceous ground cover burns, and the open, parklike stands of such fire-resistant trees as longleaf pine and turkey oak are not seriously damaged. After several years without fire, enough herbaceous growth accumulates to support fires hot enough to kill the turkey oaks and intermediate-sized pines. Both types of fire are important in maintaining the open-canopied, herb-dominated savanna. Pocket gophers are not adversely affected by these fires; in fact, they are dependent upon them for survival since the fires maintain open areas where the gophers can burrow more freely and feed on rhizomes.

Because of modern land-use practices, sandhill and scrub habitats are rapidly disappearing. Yet in many places the pocket gopher seems to be holding its own. Road shoulders, power line rights of way, and railroad embankments provide adequate habitat as well as avenues of dispersal across unfavorable areas. During a period of several years I watched a population of pocket gophers expand its territory along the road shoulder of a central Florida interstate highway. From here the animals had access to a number of disturbed habitats—lawns, orchards, and golf courses—that suited their needs. Artificially maintained habitats may provide a higher-quality environment than natural communities and may be more attractive to colonizing individuals. On the other hand, some peripheral populations have disappeared in the last several decades.

The late H.B. Sherman was very interested in southeastern pocket gophers, and during the 1930s and 1940s he collected series of animals from many areas. Since many of his collecting sites no longer support extant populations, Sherman's collections, now at the Florida State Museum, are perhaps our best documentation of the historical range of the pocket gopher in the Southeast. Sherman's studies indicate that there are four distinct species in the area, although two, *G. colonus* and *G. cumberlandius*, are confined to a small area in coastal Georgia, and another, *G. fontanelus*, is known only from the city of Savannah. *G. pinetis* occurs throughout the remainder of the coastal plain of Georgia, much of Alabama, and north and central Florida. Within this area its distribution is not uniform. Because of the taxonomic work of Sherman and others, five subspecies are recognized. These appear to have had their origins during periods of high sea levels when populations were partly or entirely isolated. During the Pleistocene, glacial ice covered major portions of North America, and sea levels receded, exposing large areas of land. Throughout the area vast savannas developed. Most of the larger animals that lived on the savannas died out toward the end of the Pleistocene, but some, such as llamas, peccaries, and tapirs, extended their ranges into South America as their north temperate populations were being extirpated.

Several years ago, while examining a rich Pleistocene fossil bed near Gainesville, Florida, paleontologist David Webb of the Florida State Museum and I found remains not only of ground sloths, camels, giant tortoises, hyenas, and giant cats but also of smaller fauna. Webb showed me fossil fragments of harvest mice, rabbits, cotton rats, rice rats, and pocket gophers. The gopher fossils dated back 7,000 to 2 million years, yet were similar in all measurements to recent *G. pinetis.* At the same time, they cannot be separated with any precision from species from the Southwest.

Based on patterns of distribution, the southeastern pocket gopher is of western origin. Many other species found in the same plant communities occupied by southeastern pocket gophers also originated in the West. The American whip scorpion, eastern diamondback rattlesnake, indigo snake, gopher tortoise, scrub jay, and burrowing owl are but a few of the "western" species found in the Southeast. Most are found in close association with sandhill and scrub habitats, some exclusively so. Many plants with similar distributional histories combine with the fauna to form a "western" landscape.

The fossil record of pocket gophers is not the only indicator of a long history in the Southeast. Perhaps just as revealing is the large assemblage of animals that has evolved within the protective confines of the pocket gopher's burrow system. The burrow is an environment in which exposed rootlets, stores of roots, bulbs, and rhizomes, and the pocket gopher's grass nest furnish nourishment for many insects and other arthropods. Forty years ago two entomologists from the University of Florida, T.H. Hubbell and C.C. Goff, investigated the commensal arthropods of pocket gopher burrows. Of the sixty species they found living in the passageways, at least fifteen were highly modified for subterranean life and have never been found anywhere except in pocket gopher burrows. One of the most common inhabitants is a blind camel cricket, *Typhloceuthophilus floridanus.* In appearance, this unpigmented insect with its elongated appendages is as impressive as its name. Like many inhabitants of pocket gopher burrows, the camel cricket appears to be a scavenger, feeding on fecal material and organic debris. The pocket gopher itself is host to many specialized internal and external parasites, most of which occur exclusively in or on *Geomys.* The name *Geomydoecus scleritus*, given to a certain biting louse that usually infests pocket gophers heavily, reflects this exclusive relationship. Humus and decaying debris provide a food source for mites, springtails, and minute arthropods. These, in turn, are food for a variety of small predators—spiders, centipedes, and beetles—indigenous to these burrow systems.

Although pocket gophers do not normally eat insects, they must present a considerable hazard to their small coinhabitants because in its comings and goings, a pocket gopher's body practically fills its narrow underground runways. In order not to be crushed or buried in the soil that is often pushed in front of the gopher as it hurries along, delicately built insects such as the camel cricket must stay in different passageways or in small tunnels that they excavate for themselves. Captive blind camel crickets maintained in artificial burrows are quick to respond to any vibration by seeking some retreat. Those that cannot find cover scamper wildly about, then run down the burrows away from the disturbance until they locate a place of concealment.

Attempting to collect some of these commensal arthropods, I found that they fled from my digging activities and, in particular, the air that entered the exposed tunnels. Only if the tunnels were sealed from the outside would the various insect traps that I placed in the runways achieve results. Trapped insects had to be maintained in closed containers with high humidity; prolonged exposure to the outside environment proved fatal to most of them. Unable to survive outside the burrow, these specialized insects must disperse from burrow to burrow through temporary connections made by the gophers during the mating season or when the young tunnel off from the mother's system. This dispersal method must be an effective one, for every burrow system examined contained large numbers of these specialized arthropods.

There are also many free-living organisms commonly associated with the mounds of soil pushed up by pocket gophers. In the early 1960s, John Funderburg and I made an intensive study of the fauna associated with pocket gopher mounds. Frequent ground fires leave large areas almost bare of surface debris, and we found that animals seeking cover often used pocket gopher mounds as a refuge. Numerous invertebrates and at least twenty species of reptiles and amphibians were discov-

*Although males may occasionally come to the surface in search of a mate, pocket gophers spend almost all of their time below ground. As a consequence, they are seldom the victims of predators.*

ered living in the mounds. One-third of these were fossorial species that seem to be regular inhabitants of the mounds, and some, such as the sand skink and the mole skink, were seldom encountered anywhere else. The moist earth in the mounds creates a microhabitat that appears to be an important factor in the maintenance of certain amphibian populations during prolonged periods of drought, and several species of reptiles regularly use the mounds as a site for depositing their thin-shelled, leathery eggs. I have not conducted any follow-up studies to test the importance of this type of cover for small terrestrial animals, but from my observations I believe that several species would have difficulty living in scrub and sandhill habitats if it were not for these mounds. Most would probably exist at lower population densities.

Although there have been no studies in the Southeast, the impact of the gopher's digging has been documented in other regions. A thirty-year study of the northern pocket gopher, *Thomomys talpoides*, in Utah revealed that noncapillary porosity, organic matter, total nitrogen, and total phosphorus of the soil were considerably higher in areas where the rodent was present. This strongly suggests that *Geomys* may have an important role in the soil composition of natural upland habitats of the Southeast.

The current center of abundance of the southeastern pocket gopher is in north-central Florida, where numerous sand ridges provide great expanses of suitable habitat. Densities decrease outward from this area, with many outlying relict and semirelict populations in Florida, southern Georgia, and Alabama. The exact pattern of dispersal and later isolation are difficult to explain. Today the species is absent from many areas where apparently suitable habitat exists. Rivers, which could theoretically provide barriers to dispersal, might explain the absence of pocket gophers from some localities but seem to have little effect in preventing colonization of other areas.

There is considerable documentation, in historical times, of the decreasing range of the southeastern pocket gopher. Early lumbering removed most of the larger stands of longleaf pine, and in some of these areas thickets of turkey oak now predominate. More recent forestry practices use monocultures of faster-growing pines. In areas where there has not been extensive site preparation, pocket gophers are able to persist until the rows of young pines reach an age where they form a closed canopy. Then the herbaceous layer disappears and so do the pocket gophers. Because of the vast acreage of these tree farms, there is little opportunity for the animals to dis-

*Pocket gophers are highly tolerant of the raised levels of carbon dioxide in their sealed burrow systems, and their low rate of metabolism helps to limit both oxygen consumption and respiratory water loss.*

perse to newly cleared areas. The older residents of large sections of Georgia and Alabama remember "sandy-mounders" in places where they no longer occur. Forest fire-prevention policies have undoubtedly had a major impact on many fire-dependent savanna ecosystems. Annual plowing also eliminates pocket gophers from extensive agricultural areas. Farmers often kill animals that find refuge in bordering areas because these rodents do not restrict their diet to the rhizomes of grasses when something else is available. Young citrus groves provide suitable habitat, but many grove managers believe that gophers eat the trees' roots and usually try to trap them out.

Deprived of their ancestral habitat, southeastern pocket gophers are either extirpated or forced into artificially maintained habitats where they often become pests. In its native environment this beautifully adapted and highly specialized survivor of a Pleistocene ecosystem is an important contributor to its community, deserving of more than remnant stands of savanna and scrub. □

# Artful Diners

*For some caterpillars, table manners are a matter of life and death*

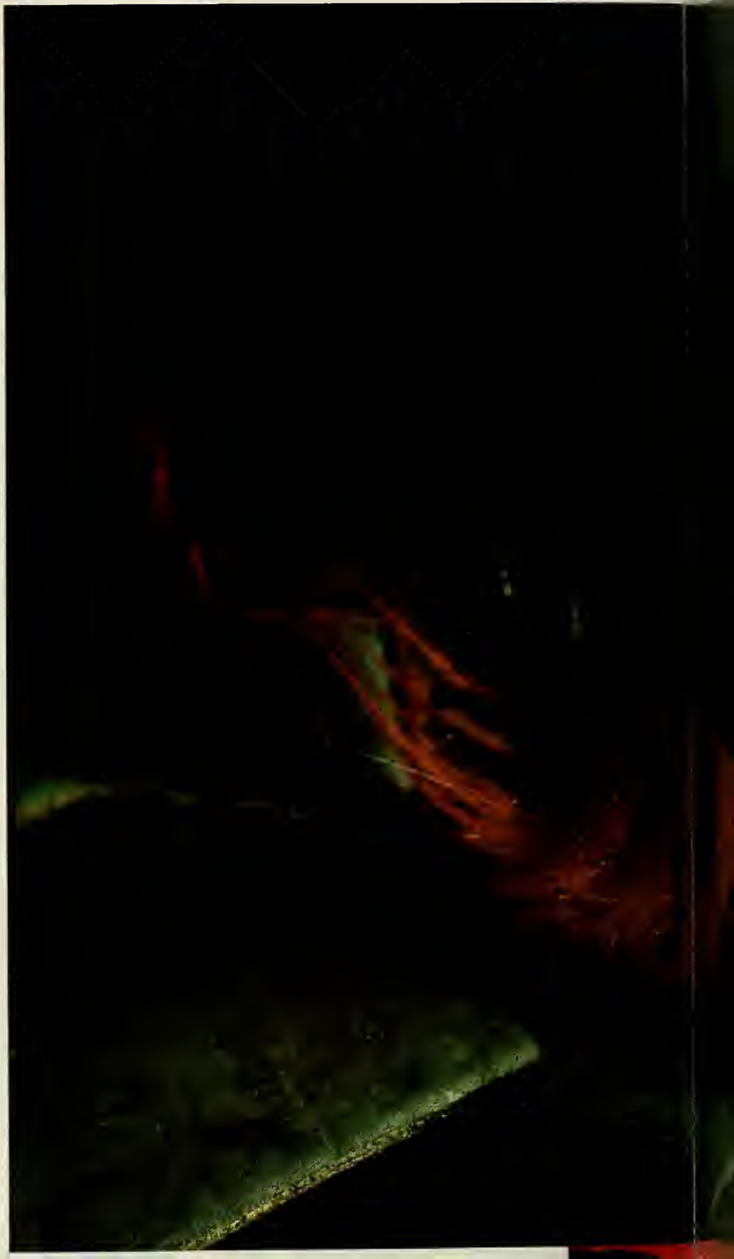
by **Bernd Heinrich**

After the trees regain their foliage in the spring, the larvae of innumerable species of moths and butterflies begin to feed on the leaves. In turn, the forests are invaded by hordes of birds that feed the larvae to their rapidly growing young. Thus, the danger of predation is high for many caterpillars. Nevertheless, their primary task is to feed and assimilate food that may be the sole supply of energy for the activity and reproduction of their adult phases.

Vertebrate herbivores also have to cope with predation. Squirrels, rabbits, and deer spend a large part of their foraging time scanning for predators and must often compromise feeding efficiency in order to be prepared to flee. Caterpillars, because they move so slowly, can do relatively little to escape birds that detect them. Their main defenses are to remain undetected or taste so bad that birds won't bother them. And bad taste must be advertised if it is to do its work in time, so noxious caterpillars are usually brightly colored and conspicuous.

The evolved strategies of using poisons and irritating hairs and spines, as well as intimidating displays, are highly effective in repelling birds and other potential predators. But none of these strategies is effective against all predators at all times, particularly if a predator is hungry enough. The ideal strategy is to remain totally undetected. Some caterpillars approach this ideal, and the variety and sophistication of the strategies used by the hundreds of thousands of lepidopteran species to remain undetected bring to mind the words of the distinguished nineteenth-century naturalist Louis Agassiz: "The possibilities of existence run so deeply into the extravagant that there is scarcely any conception too extraordinary for Nature to realize."

The extravagances of caterpillars, and their effectiveness, are well documented in a vast body of literature that has been produced over the past century on the subject. But one problem has not yet received attention.



*Not a dog at all, but a moth larva (family Megalopygidae), this South American caterpillar is not pleasant to pet or to eat. Its hairs come off and lodge in the throats of predators, and stinging spines under the hairs add to its defenses. Thus armed and conspicuous, this caterpillar has no need to hide leaf damage, as its messily chewed perch attests.*

*Far left: This stick caterpillar (family Geometridae) feeds at night and remains motionless all day, at some remove from the leaf damage it has caused. It eases the strain of maintaining immobility by spinning a silk thread to tie its head to a twig. On the other hand, the saddleback caterpillar (family Eucleidae), left, advertises its stinging hairs with bright colors.*

Hugh B. Cott, who brought the subject of caterpillar defenses against predators up to date thirty years ago in a fascinating book, inadvertently suggests the problem when he describes a sphinx larva so effectively camouflaged that it "may as easily be discovered with the hand as with the eye. . . . The only clue as to its whereabouts is partially eaten leaves."

The problem, which neither Cott nor anyone since has investigated, is leaf damage. Do birds key in on leaf damage in searching for caterpillars? If so, then to remain totally undetected may present a problem to a caterpillar that uses its food, the leaves, as a source of cover. A caterpillar that consumes the cover over its head not only exposes itself but also leaves an indelible record of where it has been. It would seem that the caterpillars must do something to avoid this problem, and indeed, while studying the foraging behavior of caterpillars near Lake Itasca in northern Minnesota I found that a variety of caterpillar foraging strategies seem to have evolved as a compromise between feeding efficiently and avoiding predators.

Leaves come in an incredible array of shapes and sizes, varying from the long, needle-shaped leaves of pine to the broad ovals of tobacco. Sophisticated handling techniques are required to harvest these efficiently. Bees learn to handle different kinds of flowers to get the pollen and nectar, but for the most part each species of caterpillar feeds on one species of plant, and the way in which a caterpillar handles the leaves is inborn and automatic, having been fine-tuned through eons of natural selection.

In some cases the feeding behavior seems to have been shaped primarily to enhance feeding efficiency, rather than predator avoidance. The pine sphinx caterpillar, for example, is long and green striped, mimicking a group of pine needles. The caterpillar could potentially feed in the simplest way by biting into the nearest leaf tissue available (thus chopping needles off). It does not do so, however, unless it is confined in the crowded quarters of a jar or other container. When on a free branch, a larva always feeds on needles one at a time by "walking" up to the tip of a needle with its prolegs (while its clasper remains anchored near the base). The leaf bends, and the caterpillar begins to feed only when it reaches the tip. It then proceeds to eat the needle down to the base. After finishing, it "walks" up another needle to repeat the process. As a result of this behavior, no food drops to the ground to be wasted.

The consequences of wasting food are potentially critical for larvae that have large appetites and feed on small herbs that are scarce or widely distributed relative to the caterpillar's locomotor abilities. In the Mojave Desert, for example, the caterpillars of the tobacco sphinx feed on jimson weed. The widely scattered food plants are a scarce resource and are sometimes denuded by these caterpillars. In the laboratory ten years ago I observed that these caterpillars eat entire tobacco leaves by remaining under a leaf near the base, feeding forward from the petiole, and bending the leaf as feeding proceeds gradually to the tip.

Leaf bending not only results in economical harvesting but also shields the caterpillar from the sun and predators. The caterpillars routinely bite into the midrib and petiole near the base, thus bending the leaf toward them more easily, but they do not chew through the leaf near their perch, which would waste considerable amounts of food.

Not all feeding behaviors evolved for efficiency, however. Anne J. Alexander reported nearly twenty years ago that the larvae of certain heliconiid butterflies in Trinidad that feed on the leaves of passion flower plants (Passifloraceae) weave silk between the stalk of the leaf and the stem to which it is attached. These silk attachments guard against the leaf being detached while the caterpillar is on it. (Possibly the plant attempts to protect itself by shedding leaves that hold a caterpillar.)

Some heliconiid larvae crawl to the tip of a leaf, turn around, and then chew furrows into the leaf to the midrib. They then eat the portion of the leaf they have marked off. Alexander speculates that the furrows serve as territorial markers, moats of a sort, that may aid a caterpillar in defending its feeding ground against other larvae or predators. An alternative explanation is that the furrows are barriers against a chemical defense mounted by the plant against the caterpillar.

One South American caterpillar (genus *Anaea*) carves up the leaf of its food plant to leave uneaten a number of rough models of itself dangling near the midrib on which it perches. Presumably, birds pecking at the models are discouraged from finding the real caterpillar.

We know from many examples that the way caterpillars manipulate and feed on leaves is a highly complex behavior that has evolved under a variety of selective pressures. But we are not

Bernd Heinrich

*A dagger moth larva (*Acronita leporina*), thought to mimic the foam of spittlebugs or bird droppings, feeds while perched on top of leaves. To avoid leaving noticeable leaf damage that would attract birds, it "cleans its plate." After finishing a meal, it backs down the stem and snips off the remnant of leaf. Neatly severed stalks of previous meals are visible in the background of this sequence.*

certain that birds hunt for caterpillars the way most humans do—by looking for leaf damage. We can, however, examine the potential for such behavior. In addition, whatever cues they may use in locating caterpillars, the birds' searching strategies should have, over the millions of years, resulted in the caterpillars evolving counterstrategies. Thus, the behaviors of the caterpillars may reflect the hunting strategies of the birds.

The ability to recognize damaged leaves rests, first of all, on the ability to discriminate between different geometrical shapes. This ability is well documented not only in birds and other vertebrate animals but also in insects. Karl von Frisch long ago showed that honeybees learn to associate reward with specific geometrical designs. Other experimenters have shown that common pigeons, which normally have no need to differentiate leaf shapes, are able to discriminate between elm, maple, and sassafrass leaves, provided they are motivated by food rewards. (It is important to note that the pigeons are discriminating between classes of objects, for none of the leaves of any one species are identical.)

Russ Greenberg of the University of California at Berkeley has shown that in Panama the blue dacnis flies directly to leaves with feeding damage to glean insects, and the scarlet-rumped cacique specializes on insects hidden in leaf rolls. Also, in a study of the foraging behavior of the northern oriole in Colorado during an outbreak of pyralid moth caterpillars on cottonwood, Bruce Edinger of the University of Minnesota found that the birds keyed in on rolled leaves, unrolling them to extricate caterpillars that were totally hidden from view.

Rolling a leaf up and eating the roll from the inside is but one of many strategies evolved by caterpillars to escape predation. Like most such strategies, however, it is only effective until "found out" by the predator, and it is only found out, thus becoming disadvantageous, when it is common. This principle was demonstrated in 1952 by L. De Ruiter of Oxford University in his experiments on the camouflage of caterpillars that mimic sticks. De Ruiter found that chaffinches and jays do not normally peck at sticks, but if a bird accidentally finds a stick caterpillar, then it pecks at sticks that resemble these caterpillars. The birds continue this behavior only if they are rewarded occasionally. If the stick caterpillars become rare, the birds gradually desist from pecking sticks and stick caterpillars. Thus, when they are rare, camouflaged caterpillars enjoy relative immunity from predation, but when they reach epidemic proportions, they are disproportionately preyed upon and their populations are generally stabilized.

The same principles appear to apply to all predators, including humans. As a simple test I led my field ecology class at the Lake Itasca Biological Station to a balsam poplar sapling and instructed them to search for the four camouflaged caterpillars I knew to be on it. In previous tests they had all discovered different species of brightly colored noxious caterpillars within seconds. Search time was only limited by the time needed to scan the foliage.

This time, however, the sapling contained four stick caterpillars. The "predators" did not know what to expect, and they were instructed not to disclose to each other what they might discover so that they would search independently and without expectation. It required fifteen minutes before one of the six persons found one of the three 1.3-inch-long larvae. Thirty-six minutes elapsed before anyone found the other species of stick caterpillar measuring 1.6 inches in length. Two people with normal eyesight had not found the latter caterpillar after one hour, when I terminated the experiment because of student unrest.

Although the caterpillar leaf damage was evident at a glance, the larvae, which remain motionless throughout the daylight hours, were not resting near the leaf damage left from their nocturnal feeding. The leaf damage in this case was a reliable cue only insofar as it directed search to the appropriate tree. Like the hidden sphinx larvae de-

scribed by Cott, the caterpillars would have been discovered by the naïve human predators much sooner had they searched by hand rather than by eye. One person who did not find the large caterpillar nevertheless noticed a small nymph of a pentatomid bug walking within two millimeters of the caterpillar. Like De Ruiter's chaffinches and jays, the students, after seeing one caterpillar, were able to locate all of them within four minutes, even though they had been placed on another sapling. The experiment was repeated with other camouflaged caterpillars, and the results were similar.

The tendency of the untrained human predators was first of all to scan for chewed foliage. I would be surprised if birds, to whom finding caterpillars is a matter of life and death, rather than fun or college credits, did not also make use of this and other cues. A whole tree can be scanned for leaf damage in seconds, thus localizing subsequent detailed search.

The obvious strategy of the stick caterpillars, which I found to be shared by many other caterpillars prized by birds, was to feed only at night, when no birds were hunting for them, and to hide at some distance from the feeding area. A brown larva of the Abbot's sphinx moth, for example, often hid all day, pressed motionless against a grapevine, its food plant, six or more feet away from the large leaves that it could not possibly consume in one meal. This strategy is costly in terms of feeding efficiency because the early summer nights in the north are much shorter and cooler than the days. By feeding only at night, the caterpillars more than halve the time available for feeding; also, cool caterpillars feed much more slowly than warm ones.

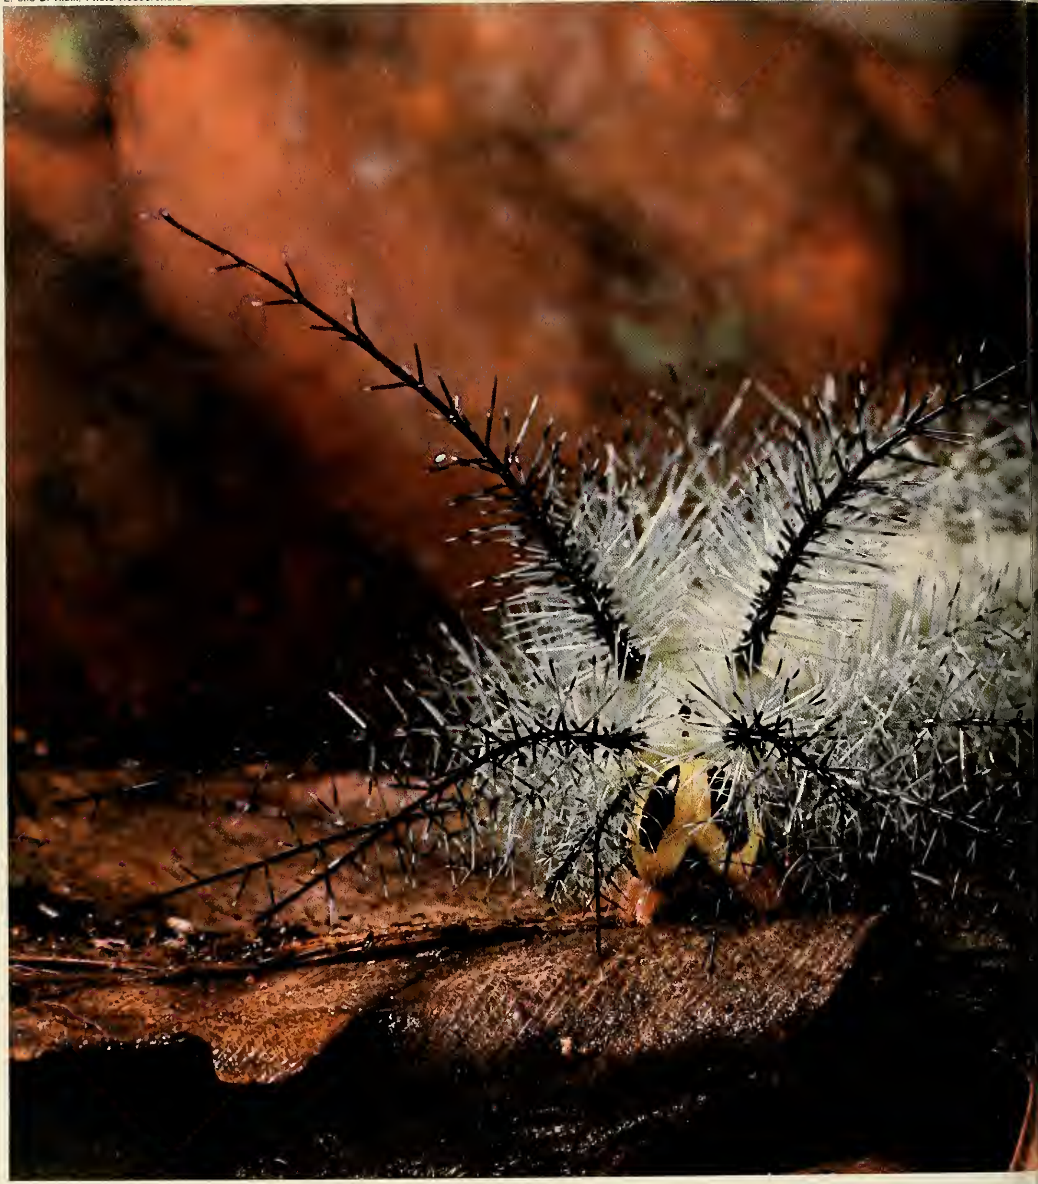
Some edible caterpillars eat both day and night, remaining permanently at the leaf without moving as much as a half inch from the feeding position until a leaf is finished. These caterpillars waste little time and motion and grow quickly through the dangerous larval period. But their camouflage must be excellent, and they must have a strategy to deal with the problem presented earlier: they must minimize the appearance of leaf damage. They do this in various ways.

The larvae of the hummingbird clearwing sphinx moth chew first one side and then the other of the leaves of viburnum, their food plant, gradually paring a leaf down in size, rather than chewing holes into it. While feeding, they remain partially covered by the leaf. The Cerisy's sphinx larva feeds at each poplar leaf until it is completely consumed before moving to the next leaf. A number of notodontid larvae combine mimicry of the leaf or the leaf petiole with a strategy of minimization of apparent leaf damage by resembling the leaf edge that they have just eaten. They feed forward on the leaf, "fitting in" the leaf they have consumed. To do this they attach themselves to the leaf edge rather than to the midrib or petiole. They mimic the leaf in its finest details, including blemishes, and in one species (*Nerice bidentata*) that feeds on elm, the jagged, toothed edge of the leaf.

In contrast to the above "clean" feeders, all of the noxious (spiny, poisonous) caterpillars are "messy" eaters. They feed while perched on the top of the leaf, often plainly visible, and leave conspicuous holes in the leaves, which can be seen from afar. For example, while feeding on willow, the spiny mourning cloak butterfly larvae generally consume the leaves to the midrib, starting from the base of the leaf and moving toward the tip. The tip of the leaf is usually left uneaten before the caterpillar starts on another nearby leaf. When many of these communal caterpillars are crowded together, they move around and eventually consume most of the leaves, leaving only the petioles and midribs. But when individual caterpillars are put on plants, they always leave messy, tattered leaves; no single leaf is fully consumed. Other unpalatable caterpillars, such as the poisonous monarch larvae, also only eat a portion of each leaf, leaving the rest on the plant. The hairy, unpalatable tent caterpillars leave conspicuous tatters on the huge, unfinished basswood leaves. But leaf size does not appear to be important: they also do not finish smaller leaves such as poplar and cherry.

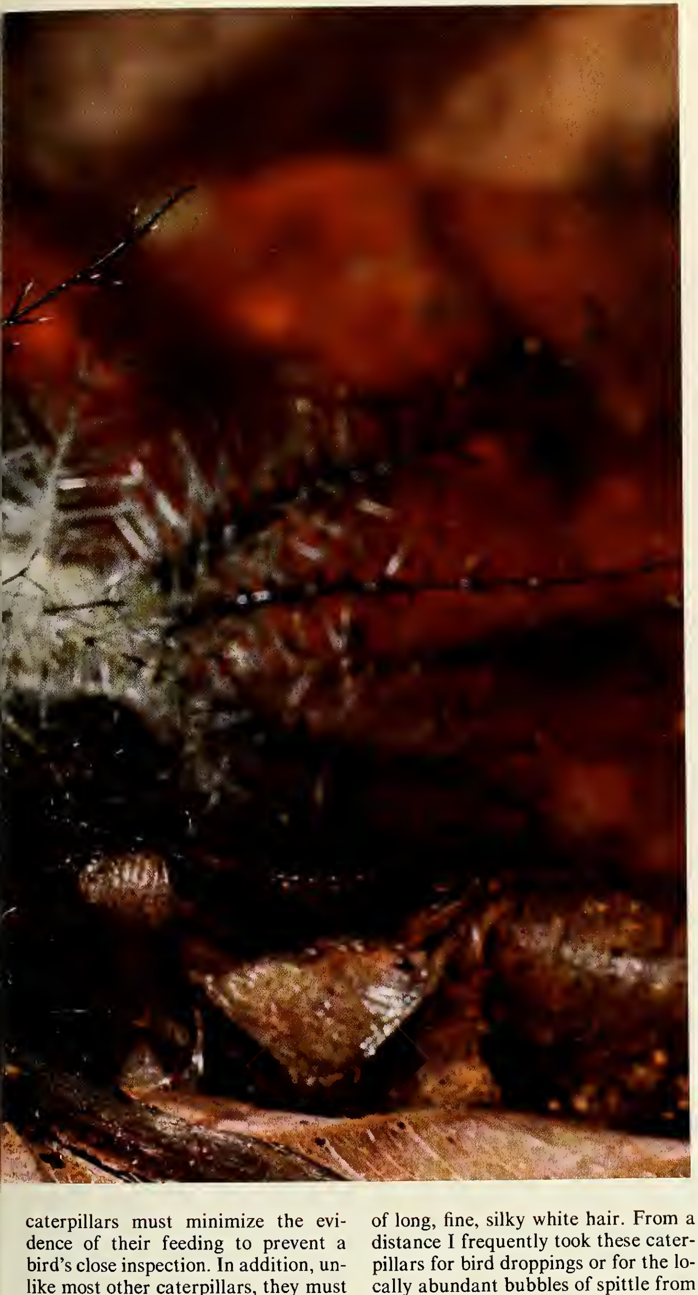
Messy feeding can, however, be raised to a fine art to confuse predators. The American copper underwing larvae also feed on basswood leaves, but unlike the tent caterpillars, these green larvae are highly desirable to birds. These caterpillars always remain underneath the basswood leaves, and they are particularly fond of hiding *between* two partially overlapping leaves. One large basswood leaf can supply most if not all the food for the entire larval growth of one of these

L. and D. Klein, Photo Researchers



small caterpillars. A larva could thus, because it has to feed, be condemned to advertise its presence for its entire life by the holes it leaves. However, after chewing a hole in a leaf from their hiding place beneath the leaf, these caterpillars immediately shift position, moving three feet or more to chew another hole in a distant leaf. As a consequence, a branch with one of these caterpillars soon has numerous leaves marked by conspicuous small holes, but the majority of these leaves have no caterpillar near them.

In contrast to hiding and blending in with the background, a variety of caterpillars all over the world have evolved to be white and visible. They rest and feed conspicuously from the top surface of leaves. It is thought that they mimic bird droppings, groups of woolly aphids, or possibly the spittle from spittlebugs. All of these models are inedible to birds, and the caterpillars' defense lies in being falsely identified. It is to their advantage to be seen from afar, since close examination would reveal any imperfections of their mimicry. If birds use leaf damage to localize their search, then these



*The emperor moth caterpillar (family Saturnidae), with its elaborate spines, has no need of camouflage.*

caterpillars must minimize the evidence of their feeding to prevent a bird's close inspection. In addition, unlike most other caterpillars, they must perch directly on the leaf surface, rather than on the petiole or underneath on the midrib. This should have consequences for their feeding behavior.

At Lake Itasca I observed larvae of two species of dagger moths with coats of long, fine, silky white hair. From a distance I frequently took these caterpillars for bird droppings or for the locally abundant bubbles of spittle from spittlebugs. (I was surprised to see them change their disguise overnight. Just before they start to wander on the ground to search for a pupation site, these caterpillars molt their skin, shedding their bright white coat for one with drab-colored hair that blends in with the background.)

As predicted, being on the leaf at all times while still growing, these caterpillars fed both day and night. But their feeding behavior showed other surprises. First, they fed alternately on each side of the leaf, gradually whittling it smaller and reducing their perch. Obviously, the remnant of the leaf could only be eaten from the petiole, but perching on the petiole would be inconsistent with their disguise: bird droppings are not attached to leaf petioles. One might predict that the simplest behavior of the caterpillars would be to crawl headfirst off a leaf when the perch becomes too small and climb onto a neighboring leaf, leaving behind a partially eaten leaf.

The actual behavior is by no means so simple. Because I never found partially eaten leaves near these caterpillars, I therefore made detailed observations to determine how they might dispose of them. Invariably, after the leaf perch became too small, the caterpillar backed down the petiole, stopped for a few seconds to chew through the petiole until the leaf remnant was clipped off, and only then, turned around to walk headfirst down the remainder of the petiole toward another, neighboring leaf. This highly complex behavior could not have evolved if it did not have functional significance, and it would have been perfected only under strong selective pressure, particularly since it wasted potential food.

The leaf-clipping behavior of edible caterpillars that mimic conspicuous inedible objects should be advantageous to other caterpillars as well. If birds cue in on leaf damage, they might also find camouflaged caterpillars that only feed at night and hide in the daytime. A caterpillar can only creep several feet on its food plant —distances that mean little to a foraging bird. A caterpillar well hidden on a twig might still be found by a bird searching near the leaf damage left by the caterpillar during its nocturnal feeding.

At Lake Itasca I found (after some practice) many catocola underwing moth caterpillars resting on basswood twigs that showed no overt leaf damage. Looking closer, I found that some of these apparently ungrazed limbs had nearly as many petiole stubs as whole leaves. It seemed unlikely that an underwing larva could eat a whole leaf in one night. The answer to this puzzle could be found by looking at the ground. Cleared ground under basswood trees was frequently littered with green leaves, and almost all of them were partially eaten in the feeding patterns of the underwing caterpillar. In addition, these fresh leaves on the ground had short petioles, rather than the typically long petioles of whole leaves. Leaves do not spontaneously fall off by breaking at their strongest area—the petiole. (The few whole leaves on the ground had the full length of the petiole attached to them.) These observations raised the interesting question, Could these caterpillars also be clipping off the leaves after feeding on them? I started to watch the underwing caterpillars feeding behavior directly and observed that, as in the dagger moth larvae, after a caterpillar finished a bout of feeding, it backed down the petiole and then chewed through it, causing the leaf to drop off. The caterpillar then turned around, crawled along the branch, and resumed its hiding posture on the branch, four to eight inches from where it had fed.

After making these surprising observations, I looked more closely at other caterpillars and observed the same behavior in another underwing caterpillar feeding on poplar, in the waved sphinx feeding on ash, and in big poplar sphinxes feeding on willow, with extremely short petioles, as well as on cottonwood, with extremely long ones. I also observed the behavior occasionally in the Abbot's grape sphinx and in a notodontid leaf-edge-mimicking larva on oak.

Furthermore, I found large numbers of partially eaten, chewed-off leaves under other forest trees—white birch, red oak, burr oak, and elm. Along one gravel road shaded by forest trees I found as many as forty-seven clipped leaves per square yard along the roadside, and for miles, the roadside was littered with freshly clipped leaves. I did not succeed in finding out which caterpillars had cut off these leaves, but once I started looking for partially eaten, clipped leaves, they suddenly became ubiquitous wherever there were trees over bare ground.

The practice of clipping off the remainder of the leaf after feeding appears to be a behavior common to many caterpillars and results in considerable wasted food. Interestingly, sphinx caterpillars that usually clipped off leaf remnants stopped this behavior on the last several leaves eaten before leaving the plant to pupate.

The leaf-clipping behavior is by no

*Scent papillae extended to emit a noxious chemical, this West African caterpillar (family Papilionidae) is using its second line of defense against predators, which it calls into play when its camouflage fails.*

means a haphazard accidental process. For example, Abbot's sphinx larvae chew through the petiole at a relatively specific point two to five millimeters from the leaf blade; nearly the whole long petiole is left on the vine. Since the vine and the petiole are of similar thickness and appearance, the caterpillar may thus avoid cutting through the entire vine (thereby destroying its entire food supply) by mistake. Caterpillars that are hairy, spiny, or poisonous, such as the tent caterpillars and the larvae of the monarch and mourning cloak butterflies, never chew through the petiole after finishing a leaf. Those caterpillars that eat the entire leaf, such as the larvae of the polyphemus, puss, and Cerisy's sphinx moths, do so occasionally.

In addition to leaf clipping, various other feeding behaviors of caterpillars may well have evolved under the selective pressure exerted by foraging birds. If this hypothesis is true, it has something to say not only about the caterpillars but also about the birds, whose foraging behavior may be more complex and sophisticated than previously thought. ☐

Kjell B. Sandved

# WHAT DO YOU THINK IT IS?

Need some help? Then consider the following:

The car you're looking at has a CIS fuel-injected engine that can take you from 0 to 50 in 8.5 seconds.

And power-assisted disc drum brakes that can take you from 50 to 0 in less than three.

It has 4-wheel independent suspension to keep you from going like this on bad roads.

And front-wheel drive to give you responsive handling even in bad weather.

In back, there's a trunk so large it can hold six suitcases.

All standing up.

And inside, there's room enough for a family of four.

Got it yet?

Well, maybe it would help to know that for all its impressive performance on the road, this car still turns in a pretty spectacular performance at the gas pump.

It gets an EPA estimated $\boxed{25}$ mpg, 40 estimated highway. (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length.

Actual highway mileage will probably be less.)

You still don't know?

Then we should probably mention one last thing.

This car doesn't look like what it is, and most people have a hard time guessing.

So why don't we just tell you.

We call it the Jetta.

Of course, Autoweek had a different name for it.

They called it, "another winner from Volkswagen."

# THINK AGAIN.

# When Hail Breaks Loose

*A phenomenon of spring and summer, hailstorms are a menace to agriculture around the globe*

**by John Hallett**

Hailstorms cause about $700 million damage a year to crops in the United States. This is more than one percent of the total United States agricultural production. Hail is primarily a phenomenon of temperate climates. The hail season in the United States is spring and summer, April through October, and the area most frequently affected is where Colorado, Nebraska, and Wyoming meet, a region known as hail alley. But hail falls frequently in the plains of Kansas, Oklahoma, and Texas, along the Pacific coast from northern California to Washington, and occasionally in every state of the union.

Hailstones vary greatly in size and shape. They can be as small as a pea or as large as a grapefruit. They can be conical, round, or oblate, dimpled or knobbed with protrusions. The largest stones weigh from one to two pounds and fall at a speed of some 100 miles per hour. People have been reported killed by hailstones in India and a 1977 plane crash in Georgia was attributed to hail. But the greatest damage from hail is to high-value crops such as fruit and vegetables and is caused by small stones that can blanket the ground and occasionally accumulate to a depth of several inches.

How is hail formed? Hail is associated with thunderstorms, and while almost all thunderstorms probably produce hailstones, only some of these storms produce hail that survives to reach the ground. The size and severity of the storm, the water content of the storm cloud, the temperature, and the strength of the vertical air currents are some of the factors that determine the kind of hailstones that will form. Large-scale, severe storms with a high moisture content and strong updrafts produce hailstones of sufficient size to fall to earth almost intact. Less vigorous storms produce only small stones, which often melt as they fall.

Clouds that produce thunder and lightning—like all clouds that meteorologists label cumulus—begin as moist air near the earth's surface. When heated by the sun, the air becomes buoyant and rises. With increasing altitude, the pressure decreases, allowing the air to expand and cool. As the moisture condenses into liquid, drops form and heat is released. Thereafter, as the cloud continues to ascend, it cools somewhat more slowly and remains warmer than its surroundings, which become progressively colder at higher levels. Upward growth continues as long as the air remains buoyant. For thunderstorms, this process stops only when the cloud reaches the tropopause, a region of the earth's atmosphere about ten miles above the ground where the temperature begins to increase, rather than decrease, with additional altitude.

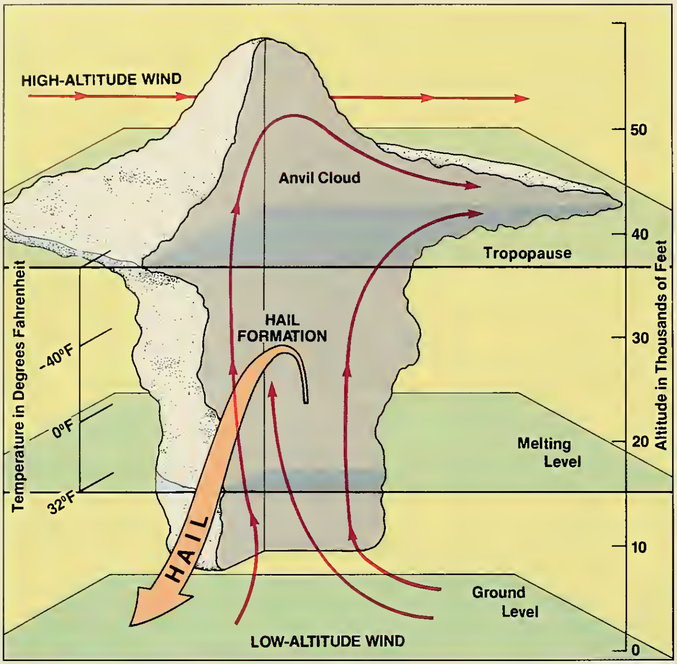
As a thunderstorm grows on a warm, sunny afternoon, the top of the puffy cumulus cloud can be seen first to grow upward and then spread out sideways when it reaches the warmer air of the tropopause. This gives the thunderstorm cloud its characteristic anvil shape. In less vigorous storms, the cloudy air rises at some 20 to 30 mph; in more severe storms the ascent can be as rapid as 100 mph. As already mentioned, this is also the speed at which the biggest hailstones fall.

At temperatures of as much as 60° F below the usual freezing point of water, clouds often consist of drops that have "supercooled," that is, have

*Hailstones come in a variety of sizes and shapes and can fall at velocities of up to 100 mph. They have been known to smash windows, dent car roofs, and kill antelope.*

Runk / Schoenberger from Grant Heilman

# Hailstone Formation



*Schematic section through a typical anvil-shaped storm cloud shows altitude and temperature at which hailstones form.*

remained liquid. Most liquids supercool in this way when divided into minute droplets. For these supercooled liquid drops to start freezing, tiny impurity particles that serve as a nucleus must be present. A bucket of water usually has many such particles, which cause the water to begin freezing at only one or two degrees below the freezing point. In a thunderstorm cloud, only about one in a million drops contains such particles, most of which are dust or tiny bits of mineral that originated in clay soils and were carried aloft by the rising air. Although the cloud drops themselves are quite small —their diameter is about the same as that of a human hair—they are still some hundred times bigger than the particles that cause them to freeze. The atoms in these particles are arranged in a hexagonal pattern just like those in natural ice crystals. Although their spacing is a little different, from the point of view of the surrounding water molecules these particles mimic an actual ice crystal and cause freezing at temperatures of only 20° or so below the freezing point of water, which is 40° higher than pure water.

After a supercooled drop freezes, it grows in the form of a snow crystal. When it reaches a size of almost one-hundredth of an inch, it can fall fast enough to collide with still liquid neighboring cloud drops. The colliding drops freeze to each other on impact and form a light, air-filled aggregate that resembles fresh snow. These aggregates are soft hail particles that grow in a conical shape and can attain a size of about a half inch. They are oriented with their growth side facing downward as they fall, collecting more and more moisture drops on their broadening base.

When cloud drops are collected in this manner at a rate so fast that there is not sufficient time for each drop to freeze individually, hard hailstones form. As additional liquid drops collide with these growing, falling hailstones, they splash against the stones and some of the drop water spreads out to form a thin liquid layer that freezes from the inside out. This process takes place with faster-falling larger stones and also with stones—approximately the size of cherries to golf balls—that grow in clouds containing a large amount of water.

In the bigger storms, the hailstones sometimes grow to resemble a wet snowball. Not enough of the heat of freezing is carried away by the air to allow the collected water to freeze solid, and a mixture of ice and water results. Differences in the amount of water present in different parts of the storm cloud through which the stone falls result in either clear or opaque ice layers on the stone. Opaque ice is caused by small air bubbles that develop if the water drops freeze so quickly that the air dissolved in the water cannot be expelled. Clear ice results from drops that freeze more slowly. Alternating layers of clear and opaque ice are characteristic of large hailstones that are kept aloft by strong updrafts as they grow in air that contains varying amounts of liquid water. A large stone may have as many as ten or more of these alternating layers, which can be readily seen when the stone is sliced into thin sections.

The center of a large stone is sometimes a conical soft hailstone; on other occasions it can be a frozen raindrop. The smaller stones grow on one side only, in the shape of a cone, like soft hail. Oblate stones result from occasional flipping while falling to the ground. Knobby stones result from the preferential collection of cloud drops on irregularities that were initially formed at random. Individual knobs can grow as long as one inch.

Only a few soft hailstones or frozen raindrops grow to become large hailstones. The updraft in the thunderclouds carries the smallest stones up and out of the cloud top; others melt as they fall. Hail that develops into large stones grows continuously, often remaining suspended near one altitude, several miles above the ground, for as long as ten to twenty minutes before falling out. This can happen when the fall velocity of the largest hailstones is identical with the maximum updraft velocity in the cloud. In storms that occur from Colorado to Texas, well-organized updrafts occasionally reach sufficiently high speeds to keep the growing hailstones aloft until they achieve the size of a grapefruit. These stones will fall when their fall velocity becomes great enough to overcome the updraft or the updraft weakens.

Can hailstorms be suppressed? Attempts to modify them have been made throughout history. The Romans shot arrows toward the storm. In medieval Europe, church bells were rung—a practice that tended to increase the casualty rate because lightning often struck the unprotected belfrey, electrocuting the bell ringer. With advancing technology, the hail cannon, a device that fired a ring of smoke and gas instead of a solid missile, became popular. The sound of the discharge was supposed to break up the hailstones. It at least provided some psychological comfort. Cannons were later replaced by rockets, which exploded aloft with a resounding bang. None of these remedies had any obvious success.

In recent years, the concept arose that artificially increasing the number of ice particles in storm clouds might produce a relatively larger number of the less damaging very small hailstones, which would melt before reaching the ground. This possibility became a reality in 1946 when it was discovered that the dispersal of pellets of dry ice, at a temperature of –95° F, or of silver iodide smoke (whose particles act on an atomic scale like tiny ice crystals) causes ice crystals to form in a sufficiently cold cloud. But this seeding technique must be used very carefully since only a small increase in the concentration of hailstones might make matters worse.

In spite of many uncertainties, hail suppression experiments have been undertaken around the world with varied claims of success. Rockets now used in the Po Valley of northern Italy contain silver iodide and are fired so as to explode in the heart of approaching storm clouds. The hope is that this will cause the production of a large number of ice crystals that will spread out and form small, harmless hailstones. Local farmers support the operation and believe it is useful. A project in Switzerland in which silver iodide smoke was released from burners on the ground indicated that while the hail was not significantly changed, the rainfall was enhanced. Aircraft seeding of hailstorms with silver iodide has been carried out in Kenya and South Africa, with claims of some hail reduction. Russian experiments in 1961 in the Caucasus, for which a striking degree of success was claimed, fired artillery shells containing silver iodide into likely looking clouds, identified by a large radar echo.

Assessing the results of these experiments is not easy. There is no doubt that the silver iodide that reaches the colder region of supercooled clouds produces ice crystals; the question is whether the crystals are distributed widely enough to have the desired effect of forming the centers of a sufficient number of small hailstones. Many scientists were and are skeptical of the statistical techniques used to claim success. Could a claimed reduction of hail have occurred through natural variability? Hail fall is notoriously changeable from place to place and time to time.

Recent experiments aimed at testing these claims of hailstone suppression were carried out in Colorado from 1972 to 1974. The experiments, designed to investigate the effect of seeding hail clouds with silver iodide released from aircraft, used an extensive array of instruments to measure the amount and size of hail falling at the ground. The results tended to be inconclusive, although very large effects, such as the 60 to 70 percent reduction in hail claimed in the Soviet Union, were ruled out.

There is still much to learn. Even if we were able to modify some hailstorms on a local scale, other storms are so large that the use of aircraft or rockets would present a formidable technological challenge, and the possibility always exists of inadvertently enhancing the hail fall on the edges of the very areas chosen for protection. Because the optimum conditions for the growth of agricultural crops and hailstorms remain the same—a warm and moist climate—raising crops in hail-prone regions will continue to be a risky undertaking for a long time to come. ☐

# Wolves in the USSR

*The state of the art of Russian wolf management*

**by Dmitri Ivanovich Bibikov**

For centuries, man has engaged in incessant and persistent struggle against the wolf, a highly organized, large predator preying on wild and domestic ungulates. This strife has resulted in wolf extermination in many Western European countries and in most of the United States. The existence of the species is endangered even in Europe's most protected mountain areas—the Pyrenees, the Apennines, the Balkans, and the Carpathians.

Diminished wolf range and numbers appear to be inevitable with increasing human transformation of the landscape, population growth, and urbanization. This process is natural and in some ways justified, since in developed areas the wolf's regular functions are taken over by man. Game management evidence from some European countries shows that high numbers of wild ungulates and their good physical condition have been achieved in the absence of the wolf. There is also no doubt that farmers, cattle breeders, and hunters would be opposed to paying a tribute to the wolf by reintroducing it into its original range.

Recently, ecologists have given strong evidence of the wolf's positive role in maintaining equilibrium in ecosystems little disturbed by man. This role consists of control of ungulate numbers and maintenance of population fitness. But the decrease of wild nature offers little chance of wolf preservation in most of its range.

*The central Russian forest wolf, which can weigh up to 175 pounds, is the largest subspecies found in the USSR. Its favored prey is moose (called elk in the Soviet Union).*

S. Marakov

In the USSR, the wolf is a common and widely distributed beast badly affecting cattle breeding and game management. Similar to the New World, in the USSR the geographical variability of the wolf has received little attention. In the Soviet Union, seven wolf subspecies have been distinguished, distinct as to size and coloration. Their ranges and morphological features call for further investigation.

The wolf is not an endangered species in the USSR. This is why control is still an urgent problem where the wolf is a human competitor, for example, in areas of extensive cattle breeding and management of ecologically important wild ungulates.

In the USSR, the current century has seen two peaks of wolf numbers, both of which followed years of war and economic difficulties when wolves were not controlled. At the end of the 1940s, the number of wolves in the country was roughly estimated at 200,000, and they were affecting cattle badly. Active control, with annual kills of 40,000 to 50,000 head, reduced the wolf population considerably by the early 1960s. The annual kill number was then fixed at 15,000.

However, the early 1970s saw a new rise in wolf numbers. In the Ukraine, in Byelorussia, and in central Russia, wolf populations increased twofold over a five-year span. The reasons were slackening control efforts, re-

Warren Garst: Tom Stack and Associates

*Ranging throughout much of temperate Europe and Asia, the red deer is essentially similar to the North American elk. Wolves take a toll of fawns and old and injured individuals.*

duced wolf density, and popularization of natural conservation. In recent years, hunting agencies and societies have contributed considerably to increased efforts at controlling wolves. Conducive to control were such measures as an increase in the premium for killed wolves: for an adult it is now up to 100 rubles and for a young, up to 50 rubles. Wolves are killed throughout the year by all means, including shooting from helicopters, vehicles, and aerosledges.

Undoubtedly, wolf numbers will again drop below the early 1970s level; that is, there will remain fewer than 50,000 wolves in the USSR. Their range in the European USSR is likely to be reduced to half of what it once was. But wolf populations in the mountains of the Caucasus, Central Asia, and Siberia are not likely to decrease in the near future. These are sparsely populated areas, difficult of access, and no effective hunting techniques are available.

Wolf populations are most vulnerable in open landscapes—tundra, steppe, and desert—where hunters use aircraft. Wolf-control data for open landscapes indicate that the tundra *Canis lupus albus* and desert *C.l. desertorum* subspecies are endangered. Preservation of genetic variety within any species being important, this can hardly be justified.

With a huge range and environmental diversity, wolf ecology in the USSR varies to a great extent geographically. First and foremost, this involves population densities and feeding. The wolf being a territorial animal, both in the Soviet Union and the United States, population density may exceed one individual per ten square miles only in such exceptional cases as in ungulate winter yards and in some reserves. For six years, sixty wolves inhabited the Kzyl-Agach reserve in Azerbaijan, an area of less than 400 square miles. The wolves maintained the population of wild boars on which they largely fed at a relatively stable level of 700 to 800 individuals. About 100 wolves dwell in the Caucasian reserve, which has an area of 1,000 square miles. Fifteen resident packs in the reserve remain in permanent home ranges of 25 to 60 square miles. Territoriality limits wolf numbers in these reserves. (These are biosphere reserves—no hunting or timber harvesting is allowed and only limited recreation is permitted.)

Wolves used to be abundant in the forest-steppe zone of central Russia, the Ukraine, Povolzhie, and western Siberia, but systematic human pressure has considerably reduced these populations. A density of ten to twenty individuals per 400 square miles has only been recorded in highly wooded, sparsely populated areas. In the tundra and desert, the wolf has always been scarce, the mean density not exceeding one to two individuals per 400 square miles. We have recorded wolf population densities of up to twenty individuals per 400 square miles in the range of the saiga antelope—an animal that has recovered greatly from near extinction—in the Aktyubinsk region of Kazakhstan.

The diet of the tundra wolf is wild and domestic caribou, and in the eastern part of the region, bighorn sheep as well. Taiga wolves feed mainly on elk. In Siberia and the Far East, the wolves' diet is supplemented by deer, roe deer, and wild boar. When ungulates are scarce, blue hare is an important component of the wolf diet. In the western forest-steppe region, the wolf takes roe deer (the Baltic republics, the Ukraine), wild boar (Byelorussia), and deer. In the desert zone, the bulk of the wolf diet includes saiga and goitred gazelle, and in the river valleys, deer and wild boar. In mountain-forest ecosystems, the wolf consumes deer, wild boar, mountain goat (in the Caucasus); mountain sheep, roe deer, deer, wild boar, and mountain goat (in the mountains of Kazakhstan and Central Asia). The role of domestic ungulates, specifically sheep and goats, increases in the wolf diet where pasture livestock farming is well developed and wild ungulate resources are small.

Seasonal variability in wolf feeding is marked by a reduction in the proportion of ungulates in the summer diet, a time when small animals are abundant. The intake of carrion also increases in summer. Feeding specialization in individual wolf families has also been recorded. For example, over a number of years the major diet component of a wolf family in the Caucasian reserve was deer; that of a neighboring family was mountain sheep and wild boar. Near the edge of this reserve, some wolf families specialized in killing domestic animals. Most frequently, those were nonterritorial groups. It appears that techniques of hunting certain prey types were passed on to offspring.

The wide dispersal of wild boar in central Russia in the 1960s and 1970s has so far not resulted in a wolf changeover to feeding on them. The wolves continue to consume their traditional diet—elk. In recent years, however, evidence has been recorded of some wolf families killing wild boar.

Studies of wolf relations with ungulate prey have been the focus of attention in the USSR. Naturally, a diversity of prey species and environmental conditions over vast areas has led to highly contradictory inferences. The wolf's role as a population quality improver is definitely not appreciated in areas where the predator under study lives on domestic animals. Many game-management specialists regard the wolf as harmful. A number of publications are available on red and axis deer population reduction by wolves, specifically where these animals have been introduced. Ungulates acclimated in game preserves invariably lose their capacity to resist wolves. The selective role of the wolf, well studied and necessary in wild nature, has been lost under such conditions.

Along with their American and Canadian colleagues, Soviet scientists have given conclusive evidence of the wolf's useful role for its prey populations in ecosystems slightly affected by man. In fact, studies in Crimean reserves have demonstrated a degeneration of red deer in an overdense population in the absence of wolves. Similarly, a sharp reduction of wolf numbers brought about a substantial increase in the number of sick caribous on the Taimyr. Similar evidence is provided by the Darwin reserve, where the elk population was healthy, its numbers increasing despite annual kills of about fifty animals by numerous wolves. Following the introduction of wolf control, the Darwin elk herd was reduced by bad skin diseases.

Observations in the Caucasian reserve revealed population growth in deer, wild boar, and mountain goat during a period of intensive wolf control, the number of the wolves being reduced to between twenty-five and thirty by 1960. The number of ungulates exceeded 30,000, and winter feeding yards were destroyed under the impact of too many animals. From 1965 to 1971, few wolves were killed, and their population increased. Ungulate populations subsequently began to decrease. From 1971 to 1975, the predator-prey ratio was stabilized at 1 to 300. This allowed an average take of 4,800 pounds of prey per wolf per year. Both pastures and the physical condition of the deer have improved. In the area under study, as in the United States, deer six years of age and older (59.2 percent) and fawns (25.1 percent) were preferentially killed by the wolves. Comparison of evidence indicates that wolves have a less deleterious effect on ungulate reproduction than human hunting, which eliminates the most productive animals.

The wolf's epizootic role is not yet clearly understood. Many authors emphasize that wolves eliminate sick members, which makes the prey population healthier. A considerable body of evidence is available, Soviet sources included, on the wolf's pathogenic role, particularly in regulating helminthoses. Also imperfectly understood is the role of the wolf in retaining the rabies virus. The wolf carries and transmits this infection in nature; however, the virus can exist in the absence of the wolf. Foxes and raccoon dogs are prime carriers in some Western European countries. It should be taken into account that in the presence of the wolf, fox numbers are not high.

Wolves hunting saigas exhibit a pronounced prey selectivity. During the rut, for instance, wolves are known to take weakened and exhausted males most frequently. Similarly, during fall saiga migrations we observed wolves keeping near small antelope groups that followed the multithousand major herds. In such small groups, the proportion of inferior and wounded individuals is high (up to 5 percent). Creating test situations through pursuit of small groups, the wolves overtake the

I. Bavykin

*Nuzzling up to their mother, two pups display the close familial bonds of wolves. Social status, so important in the hierarchy of a clan, begins to be formed at this age.*

inferior individuals lagging behind. Dead saigas, which are common on migration pathways and, specifically, at human hunting sites, are another source of easy food.

Wolves are not always so selective when preying on saigas. For instance, when wolves take pregnant females and newborn young it is a matter of chance as to which will fall prey. The death rates of pregnant females and young are negligible, however, because of the large concentrations of saigas. It appears that the concentration of many thousands of calving females in a territory of a single wolf family is an adaptation of the saiga to wolf predation. According to our observations the death rate of young saigas reaches 20 to 30 percent in the inferior groups that lag behind the main herds. Small stray groups of pregnant females are hardly a population elite, however, and their high loss of young to wolves may actually benefit animals in the major herds by reducing predator pressure on them.

No selectivity in wolves taking saigas appears to be operating at river crossings. The antelopes are aware of the water obstacle hazard and approach it with great caution, avoiding reeds and other cover that wolves use. If the predators manage to attack saigas during a crossing, losses are bound to be great: dozens of saigas of both sexes are commonly killed.

There occur situations when wolves kill quite healthy and efficient individuals. This happens under deep snow-cover conditions when frozen crust handicaps ungulate escape. The possibilities of useful selection are also limited in wild boar and Caspian seal populations, since wolves largely kill young individuals. Thus the problems of wolf–ungulate management are very complicated, no unambiguous solutions existing.

Changes in wolf ecology and behavior under human impact, in particular, years of hunting, have not yet been considered. These are of great interest, as a high degree of nervous activity in wolves has resulted, as well as a demonstration of their high capacity for adaptation to new conditions.

Although the wolf is now most abundant in sparsely populated territories, its present-day distribution is of a secondary nature, having been caused by human activities that ousted the animal from densely populated areas. As early as the beginning of the current century, the wolf's optimum range was in the forest-steppe zone where it preyed mostly on domestic animals—wild ungulates having been long exterminated. The wolf's range widened following human distributional patterns. The change in range can be best traced in the plain-taiga zone, a landscape unfavorable for the wolf because of its deep snow cover in winter. The expansion of the wolf range in this zone was fostered by the following factors: an increase in the road network due to logging (which facilitates the wolf's movement under deep snow conditions), new settlements, and better feeding conditions at the expense of wild and domestic animals. The wolf penetrated to the arid deserts of Turkmenia and Uzbekistan thanks to irrigation and formation of water reservoirs near artesian wells.

Along with a marked trend to avoid humans, the opposite behavioral pattern has also been observed in the wolf. Not infrequently, wolves have adapted to living near man to feed at dumps and livestock burial sites. A similar pattern has been revealed for coyotes in the United States.

Under conditions of human harassment, familial wolf groups tend to break up and total population numbers are reduced. The wolves acquire greater mobility; they migrate frequently and at longer distances. Our observations of wolf packs in the Smolensk region revealed that in winter wolves would often migrate over distances of 18 to 24 miles, leaving their territory completely during a single night. They would return after a few weeks, but commonly only for a short time. Extensive migrations have also been recorded in the Ryazan region.

In addition to large-scale migrations and a partial loss of territory conservatism in some wolves, a substantial change in the pattern of using killed prey has emerged in recent years. Where previously, a pack kept near the dead prey for a few days, wolves now only confine themselves to a single feeding, after which they move long distances. This new behavior precludes the use of bait to keep the wolves at the site for better hunting.

Generally, wolf behavior is most conservative. This is particularly true for their habit of howling. It would seem that an animal that changes its behavior flexibly to protect itself would find it natural to get rid of this habit, which attracts hunters and hence is fatal to survival. However, this does not happen. The communicative significance of howling must be so high that this behavior cannot be rearranged even at the hazard of species survival.

The situation in regions where the structure of the wolf population has been depleted through extensive control is quite peculiar. Unable to find a mate, lone wolves (both males and females) mate with dogs, which yields cross populations. This is a most unusual adaptation to extreme conditions created by man. Currently, such crosses have been recorded in more than ten regions in the USSR, and their numbers and ranges have been increasing. Wolf-dog crosses studied in the Voronezh region resembled wolves externally or were intermediate. The bulk had wolf fur coloration but black-and-white patches were found in many individuals. Crosses are closer to true wolves ecologically, but they are less robust, preferring to attack small livestock, fowl, and dogs. By the early 1970s nine populations of wolf-dog crosses were recorded in the Voronezh region. By 1976 only three of them remained following a recovery in wolf numbers from 22 to 26 to 230 to 250. The earlier reduction in wolf numbers followed the occupation of the woodlands by wild dogs, which badly affected all living things, deer included. With wolf population recovery, wild dog numbers were reduced. Thus the problem of wolf control is complicated enough.

The solution calls for profound studies, including the problems of the expansion of the ranges of crosses and wild dogs. In recent years wolf ecology studies in the USSR have intensified. Data obtained should form a basis of wolf control measures that will reflect a differential attitude to this animal in keeping with its actual role in the economy and wild nature. The regional projects of wolf control will reduce the wolf's range in the USSR. This reduction is necessary in many areas, but preservation of the diversity of ecological and geographical wolf forms should also be stressed. ☐

*In the central Russian twilight, a wolf pack gathers at a favored rest site on the border between dense forest and open fields. Potential prey can be easily spotted from such a vantage point.*

# Ancient Climes on the Great Plains

*Past variations in climate wrought dramatic changes in the life styles of prehistoric plains peoples. Future variations could have similarly far-reaching consequences.*

**by Reid A. Bryson**

The environmental factors that affect human occupation and use of the land must be taken into consideration if we are to understand history. Climate is one of these factors. It helped to shape the history of the American West and may play a comparable role in shaping the region's future. Two examples from American prehistory should suffice to make the point.

The Indians of the northern part of the Great Plains, a vast area that stretches roughly from the eastern slopes of the Rocky Mountains to beyond the Mississippi River, once lived in villages scattered across the region. They grew rain-fed corn and hunted deer and bison. Radiocarbon soil dating indicates that after about A.D. 1200, the villages were abandoned and became covered with wind-blown dust. Studies show that the twelfth century marked the beginning of a two-century-long period of frequent drought in the northern Great Plains. Variations in airstream patterns are presumed to have been the cause.

Similarly, the Pueblo Indians of the Mesa Verde, in what is now southwest Colorado, abandoned their homes about the year 1300 after having successfully maintained an agricultural society in the area for several centuries. Tree-ring studies indicate that a succession of severe droughts over several hundred years probably made farming impossible and caused the Pueblo Indians to migrate south and west.

Our western climate can be understood only in terms of special topographic features. The American West is primarily a high plateau, with mountain ranges that modify the flow of air across its surface. This combination of mountains and mid-latitude westerlies blowing almost at right angles to them dominates the climate of most of the North American continent, even far east of the Rockies.

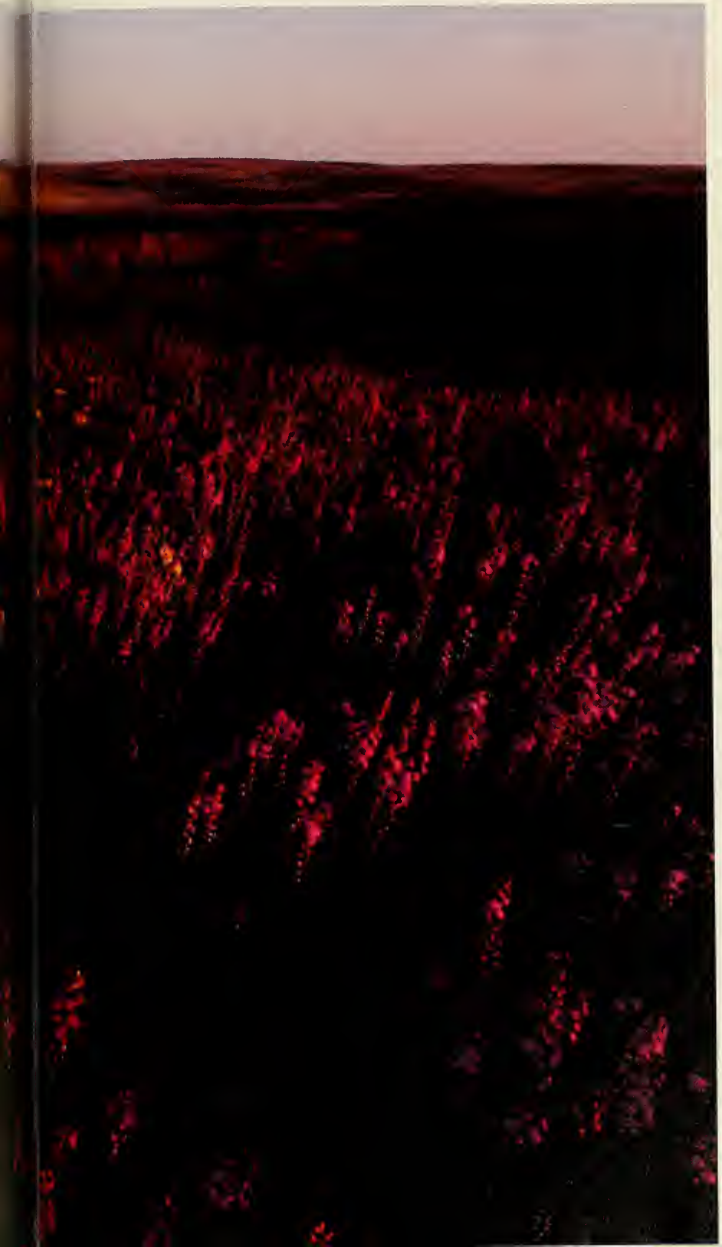
In essence, the western United States is too high for most of the moist low-level air coming from the West Coast to cross. The kinetic energy of the west winds is usually insufficient to enable the air to rise from near sea level along the Pacific coast to the crest of the Sierras and the Cascades. Much more air leaves the east side of the Cordilleras near the ground than arrives at the West Coast near the sea. (The Cordilleras is the North American mountain system that includes all the mountains between the Rockies on the east and the Pacific coast.) The excess comes from atmospheric levels near the height of the plateau—about 4,000 to 5,000 feet. Because of the location of the various western mountain ranges and the character of the air, there are three dominant routes by which this mid-level Pacific air moves eastward to the Great Plains. These may be thought of as the Southern Pacific, Union Pacific, and Canadian Pacific routes, for those railroads were laid out to take advantage of the least difficult passages through the mountain ranges.

The southern route for the eastward passage of Pacific air, roughly along the Mexican border, carries the greatest flow in winter when the westerlies are far south. This air passes over the

southwestern desert in California and Arizona and south of the Rockies, and flows across either the semiarid southern portion of the Great Plains, known as the Llano Estacado, which extends over most of the Texas Panhandle and part of New Mexico, or northward along the Front Range of the Rockies about as far as Denver. The air is seasonally hot and very dry as it descends down the slope of the mountains and into the Great Plains.

The middle air route follows the broad, lower area of the Columbia River valley on the border between Oregon and Washington, the Snake River area of southern Idaho, and the break between the southern and northern Rockies represented by the basins of Wyoming. This route is at a latitude near that of the maximum westerlies—about 40 degrees north. Its mild, dry airstream flows eastward roughly parallel to the Union Pacific Railroad route and can often be traced as far eastward as Ohio and Pennsylvania. This dry airstream coincides with the most easterly extension of the western grasslands.

The northern Pacific air route



*The upper treeline is largely determined by temperature; the lower one by dryness. As the airstreams flowing across North America shifted from one century to another, the northern forest underwent dramatic changes. Above is a contemporary woods on the edge of the prairie in South Dakota.*

*A prairie preserve in northwest Iowa, left, on the edge of the Great Plains, looks like this today. Over the centuries, the plains have changed from riparian woodlands to steppelike stretches having few trees to a "sea of grass."*

across the Canadian Rockies has no broad system of passes through which the lower-level air can flow. But the relative ease of vertical movement of the Pacific air at Canadian latitudes, combined with the strength of the westerlies, makes it possible for rather low-level Pacific air to cross the mountains. This air is mild for its latitude, even in winter, and is, of course, dry.

The eastern half of North America, with its broad Hudson Bay-Mississippi Valley system of lowlands is open to the unimpeded flow of cold arctic air southward and of warm, moist tropical air northward. Between these two extreme types of air, the west winds drive a wedge composed of the three modified varieties of Pacific air.

The seasonal dominance and interplay of all five of these air types defines the climatic regions of North America and puts controls on the distribution of plant and animal life. The variation in length of time the various airstreams dominate in a given area is at the heart of climatic change.

On special occasions when the west–east airflow overtops the mountain ranges, it undergoes compression, heating, and drying as it sinks down the leeward slopes, and a dramatic, intense chinook—a warm, dry wind—occurs. Of a milder nature but broader scale, the three Pacific airstreams also undergo warming and drying as they descend to the Great Plains. Together, these air masses set the climatic pattern of the American West.

The depth of penetration of southern and western moisture-bearing airstreams has varied in the past, causing changes in the amount of water available to the rain- or snow-bringing meteorological processes. The spilling of cold airstreams into the topographic basins of the Cordilleras has also caused widely felt changes that influenced the character of the West in earlier times and continues today to affect water supplies and agricultural practices in areas traditionally short of water.

In early summer, at about the end of June, the west winds of the mid-latitudes shift northward and contract into a smaller vortex around the North Pole. With this change the moist tropical air penetrates more readily northward over the Great Plains and extends into the southwestern United States as well. This event raises the humidity, initiates the summer rains of the Southwest, and provides midsummer showers on the northern regions of

You're back "on the road" in almost no time!

DON'T GET STRANDED!

Be Prepared with "ROADMASTER"

Professional Automobile TIRE PUMP

BIG, EZ-Read Pressure Gauge!

SALE! NOT ~~$15.~~ NOT ~~$20.~~ only $9.88

Gives 100 lbs. pressure in seconds! Completely portable! Foot-operated! Works anytime, anywhere!

Great for bikes, toys, air mattresses and floats.

It's lightweight, compact—needs no electricity, no tools, no special hookup. Simple toe action, so easy a child can do it. Saves you the hassle at gas stations. Lets you control exact amount of air pressure. Comes with 24" clamp-lock hose that fits any tire or air shock. Folds to just 12½" for easy stashaway in car trunk.

Hundreds of uses at home or away. Comes with *free valve* for your sports gear.

*A real lifesaver in emergencies—Worth many times its low, low price*. But hurry—Order Today, while supplies last! Z494021 ... Automatic Foot Pump ...... $9.88

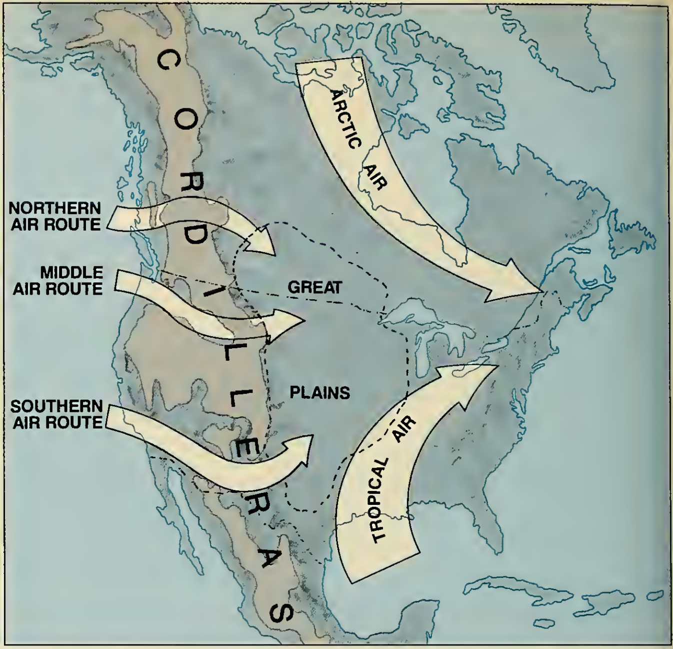
# Airflow in the American West



Joe Le Monnier

the Great Plains. At the same time the cyclonic storms of the westerlies shift northward and diminish, decreasing the rains of the Pacific Northwest and moving the warm chinook zone northward to flow across the spruce forests of Canada.

In winter, a shallow layer of cold air pours southward from the Arctic, filling the central lowlands and the plains up to about a 2,500-foot elevation, on the average, along the edge of the northern plains. The westerlies in that season are farther south than in summer and more dry air moves eastward through Wyoming and south of the Sangre de Cristo Mountains, the southernmost range of the Rockies in Colorado and New Mexico.

During relatively cool and generally more winterlike periods in earth history, the arctic air reaches farther south in summer and the westerlies are farther south and stronger. In warmer periods, the arctic air occupies a more restricted region, the westerly wedge of chinook climates is farther north, and so are the thundershowers derived from tropical air streaming northward.

The upper treeline in the United States Rockies is largely determined by temperature and the lower treeline by dryness. In similar manner, the northern Canadian treeline is bounded by year-round cold arctic air and the southern treeline by the warmth and dryness of year-round chinook-dominated air. The shifting of the airstreams from one century to another should make dramatic changes in the tundra and the northern forest and, thus, in the economic base of the peoples of the Great Plains.

I acquired personal knowledge of just such past environmental changes serendipitously in the early 1960s when my field partner, Robert Ragotzkie, a biologist-meteorologist-oceanographer at the University of Wisconsin, and I were exploring fossil soils over an area in excess of 150,000 square miles in and north of Manitoba, Canada.

In the course of our investigations, and those of some colleagues, we uncovered soils that recorded north–south movements of about 200 miles in the northern forest border along the line from Churchill, Manitoba, to Great Bear Lake in Canada's Northwest Territories. Radiocarbon dating of the soils showed that more than 3,600 years ago the forest was far north of its present limit. It subsequently retreated abruptly southward (to approximately its present position) 2,000 years ago. By the late twelfth century, it had advanced fifty to sixty miles north. A second, abrupt southward shift of the forest border in about 1200 indicated an expansion of the realm of arctic air that brought a change in the pattern of the westerlies farther south.

Data from various other sources corroborate the story of the fossil soils. The extent of sea ice and cold-induced famine years in Iceland, written records from Europe, pollen data from the Midwest, and glacial data from Switzerland all record the occurrence of cooling at the high latitudes and a southward shift of the westerlies about the year 1200.

With the use of modern data, David Baerreis, an anthropologist from the University of Wisconsin, and I reconstructed past summer rainfall changes in the United States that should have accompanied the increased strength of the summer westerlies in mid-latitudes. The reconstruction indicates that a slight expansion of the arctic area, combined with a slight increase of the westerlies in the latitudes of the United States, produces a dramatic decrease of midsummer rainfall in the northern and central regions of the Great Plains, the Northwest, and large areas of the Southwest. The reconstruction also shows more rainfall along the West Coast, but even a doubling of July precipitation in that region still doesn't represent much rain.

To verify our theory of what might have happened in the twelfth century, Baerreis and I undertook a series of excavations of Indian sites of the Mill Creek culture in northwestern Iowa, where villages appeared to be occupied after 1200. Despite the use of several types of data—plants, seeds, and pollen, for example—from a number of sites, the evidence consistently pointed to a substantial environmental change from prairies with riparian woodlands to steppelike conditions with far fewer trees. Investigation of garbage pits indicated that the meat diet of the Mill Creek villagers also changed, with a dramatic decrease in the consumption of deer—a woodland browser—and an increase in the consumption of bison—a short-grass grazer.

Our study concluded that the twelfth century marked the beginning of a two-century-long period of frequent, severe drought in the northern regions of the Great Plains. On the high parts of the plains, always more marginal for agriculture, the drought terminated the life style of prehistoric Indian tribes of the area. Farther east the Mill Creek people managed to last through most of the next two centuries, but with the strongly modified subsistence base already mentioned.

Our reconstruction also showed a complex pattern of changed rainfall in the Southwest, where numerous studies strongly indicate a disruption in the occupations of inhabitants, reduction of the area occupied, and a strong cultural modification in the twelfth and thirteenth centuries. The cultural changes included a switch from stone to adobe pueblos, as prehistoric peoples moved from canyons to broad valleys like the Rio Grande; a noticeable difference in ceramic styles; and the disappearance of the Great Kiva, a structure used for ceremonial purposes.

This account of some investigations of the thirteenth century contains a message for the future. The rainfall pattern of July 1974 (and of other recent years) had a strong similarity to the pattern of the thirteenth century. Since what has happened once can happen again, we must seriously consider whether we are at the beginning of a very long period of drought or at the end of a short period.

The droughts of the thirteenth and fourteenth centuries left the American West changed in ways that are perceived today. For example, nomadic hunters largely replaced the western villagers of the previous time. Many of the new inhabitants were Athabascans—northern people—as might have been expected with the expansion of the Arctic. The Pueblo cultures of the Southwest had also changed. The great period of the Anasazi, or Basket Makers, and of other Indian cultures such as the Mogollon was over and their area of occupation was drastically reduced. Only the Hohokam, who lived in the semiarid region of what is now central and southern Arizona and who practiced irrigation, continued in about the same numbers as before the droughts.

At about the beginning of the seventeenth century, another hemispheric climatic change occurred. The first step in hemispheric cooling, after the medieval warm period of about 900 to 1200, had occurred at about the begin-

**NATURALIST'S COLOR GUIDE**
FRANK B. SMITHE
Part I: Pocket-sized binder with 86 measured color swatches for precise description and identification of birds and other animals. $9.00.
Part II: Supplement explains how the colors and their measurements were derived. $5.00.
Both Parts I & II together $12.00.
Part III available soon.

**CURASSOWS AND RELATED BIRDS**
JEAN DELACOUR &
DEAN AMADON
Curassows, guans, and chachalacas are tropical gamebirds described in this authoritative work, with thirty color paintings and many drawings, maps, and photographs.
Cloth $20.00.

**COSTUMES OF THE EAST**
WALTER A. FAIRSERVIS, JR.
The clothing of the peoples of Asia. Beautiful color photographs and detailed drawings and maps illustrate the costumes and their functions.
Paper $5.95, cloth $15.00.

**ANCIENT MEXICO AND CENTRAL AMERICA**
GORDON F. EKHOLM
The sculpture and architecture of the precolumbian cultures of Mesoamerica. Color and black-and-white photographs by Lee Boltin.
Paper $5.00.

**BUTTERFLIES OF THE AMERICAN TROPICS**
WILLIAM PHILLIPS COMSTOCK
The genus *Anaea* is detailed in this definitive text, with thirty color plates and hundreds of drawings. The book is a collector's item.
Cloth $25.00.

ning of the thirteenth century. The second step into the "Little Ice Age" (from the thirteenth to the twentieth centuries) was largely completed immediately prior to 1600. Arctic ice expanded; many glaciers grew in such places as Iceland, Ellesmere Island in Canada's Northwest Territories, and Switzerland; the price of wheat in Europe skyrocketed; and the American West was changed climatically. We can be fairly specific about certain features of this new climatic situation because it continued into the period of scientific observation—the early 1800s—and did not end until about the beginning of the twentieth century.

To understand the changes that occurred during the Little Ice Age, we must consider a few more details of atmospheric behavior, particularly the development of the north–south meandering of the high-altitude westerly winds. When the Northern Hemisphere chills, most of the cooling takes place in the Arctic and sub-Arctic. This cooling is associated with a southward expansion of the west winds toward the equator, similar to the expansion of 1200. Additional southward movement of air masses, with further cooling, extends the west winds far enough into the tropics to produce a phenomenon called dynamic instability, in which the upper-level west winds, instead of flowing eastward with gentle north–south undulations, frequently break into great loops. These loops may carry tropical air far north into the Arctic and arctic air far south into the tropics.

From the point of view of climate, the most important attribute of these big loops of air is that they are slow-moving. Meteorologists often refer to their effects as "blocking." (The term is something of a misnomer since the loops don't actually block anything, but storms do not usually pass through them.) We know from both reconstructions and direct scientific observation that such situations were far more common during the Little Ice Age than in the twentieth century.

These blocking loops tend to be preferentially located in certain geographical areas—a northward loop, for example, located over the Cordilleras—resulting in the development of strong west–east contrasts of climate.

By the time the wave of European emigrants reached the Great Plains in the nineteenth century, conditions there had changed from those that had characterized the thirteenth and fourteenth centuries. Instead of the drought that had terminated corn agriculture over a wide area, the Great Plains had up to 30 percent more rainfall than in the modern era. North of Texas, the plains were cooler than at present in all seasons, but the Great Basin, west of the Rockies, was warmer. The rainier, cooler climate on the plains supported a "sea of grass," which, in turn, supported enormous herds of bison. (These large animals, more commonly known as buffalo, once numbered in the multimillions. They roamed over vast areas of North America in huge herds and were hunted by American Indians for their meat and hides, which were used for tents, blankets, and clothing. Nevertheless, the animals flourished until the westward migration of the European emigrants, who hunted the bison almost to extinction. By 1900 few of the animals were left.)

The increased rainfall, in both summer and winter, of the nineteenth century raises an obvious question: Why didn't the return of precipitation following two centuries of drought restore to the Great Plains the rain-nourished corn agriculture that had flourished there seven centuries earlier? I don't know the answer, but I suspect that part of it may be the sluggish behavior of the weather during periods of atmospheric instability and of block-

ing. We know that such periods are characterized in the Great Plains by both weeks of intense drought and weeks of heavy rain. The drought increases the chance of widespread grass fires; the heavy rains tend to make corn farming hazardous. Photographs from the last decades of the Little Ice Age show far fewer trees, in general, on the plains than during the period from 1930 to 1960, despite measured rainfall quantities greatly in excess of that later period.

As the Europeans moved west, resettling the regions abandoned by the Indian farmers of seven centuries earlier, leapfrogging to the West Coast and pushing into the mountains, the climate once again started to change. The Little Ice Age was ending.

Western climatic data of the 1850s period show that Taos, New Mexico, had about the same summer rainfall then as Madison, Wisconsin, has now. I live in Madison and I know that if I didn't mow my lawn all summer long, it would grow to be "stirrup high," as the grasses of the West were often described in the central high regions and parklands of the Great Plains. If we consider the carrying capacity of grasslands for bison to be proportional to that for cattle, we can then estimate the impact of the 20 to 30 percent decrease of precipitation in the Great Plains that occurred between the 1850s and the 1930–1960 period.

Using rough estimates of carrying capacity as related to rainfall, we might find that, with fifteen inches of rainfall per year, a particular range area in good condition would just support five animals. If the rainfall should decrease to ten inches per year, a percentage change that occurred over large areas in the late 1800s, the range would be overstocked, for with that rainfall, even range in good condition could only support two to three animals in the same given area. The condition of the range would thus deteriorate to an average carrying capacity of one animal on an area that once held five.

All other factors being constant, such a diminution of carrying capacity would have reduced the bison herds by about three-quarters—but other factors weren't constant. Intense hunting took place at the same time that the herds were at serious risk because of climatic change, and the combination eliminated the bison as an important food source in the Great Plains.

Farther east on the plains the extension of chinook climates affected grain farming. Wheat yield in Ellis County, in central Kansas, dropped from about fifteen bushels per acre in the 1870s to about nine in the 1890s, while corn yields dropped from about thirty bushels per acre to about twelve. If we chose one year to mark the end of the wetter era on the Great Plains, it would probably be 1883.

Data show that our perception of the western section of the Great Plains as a sea of grass supporting enormous herds of the grazing animals hunted by horse-riding nomads was only a snapshot of a transient piece of American history. So was the estimate of how many acre-feet of water in the Colorado basin could be divided up among potential users.

These perceptions would be interesting bits of lore except for the incorrect but widely held theory that climate does not change or changes so slowly that humans can always adjust. The study of western environmental history shows that the nature of the American West is closely tied to its varying climate. The facts are clear that the western climate changes significantly, sometimes rapidly, and may stay changed long enough to change the character of human cultures.

Coupled with our myths about climatic stability is our current image of ourselves as technologically self-confident if not perhaps even invincible. Whatever the contingency, whether it be flood, drought, food shortage, or environmental pollution, our technological genius will prevail.

But will cloud seeding really break a drought due to the prevalence of extended, cloudless skies and dry chinook air? Can irrigation canals, dams, and pump storage increase the normal flow of the Colorado River for apportionment? These are questions we must face up to.

As the future population and use of the American West push against the carrying capacity of the land, climatic variations will become more critical. As world population increases, the role of the West in food production likewise will become more critical. One of the few near certainties about the future is that the climate will continue to vary, as it has in the past, and the variations will doubtless again alter the economic base of the region.

Will we face the future armed with facts or encumbered with quaint perceptions and false theories? ☐

# Celestial Events

by Thomas D. Nicholson

**The Moon** The evening moon shows up as a slender crescent in the west after sunset about June 15. First-quarter follows on the 20th and full moon on the 28th, when the moon is up from sundown until sunrise. In early and late June, the moon rises after dark and remains in the sky past dawn. Last-quarter is on June 5, new moon on the 12th. Phases in July are: last-quarter on the 5th, new moon on the 12th, first-quarter on the 20th, and full moon on the 27th. Perigee moon (nearest the earth) occurs on June 8 and July 4 and 30; apogee (farthest from the earth) on June 21 and July 18. Occultations by the moon include Aldebaran (June 11 and July 9), Regulus (June 17 and July 15), Jupiter (June 18 and July 15), Saturn (June 19 and July 17), and Venus (July 9), but most are unfavorable for North American viewing.

**Stars and Planets** From the 11th to the 15th, all the planets are evening stars, above the horizon at sunset. More important for viewers, all five bright planets (visible without a telescope) are favorably placed for evening viewing in the first week of June. Venus is past its prime but still bright and high enough to be easily seen low in the west after sundown. Mercury is right next to it on the 1st, still close on the 2nd and 3rd. By the 5th, Venus may be too low at sundown; Mercury holds its position past midmonth, although it is fading rapidly.

The planets that gathered in Leo this winter, Jupiter, Mars, and Saturn, are still there but are now well spread out in the southwest after dark. The moon moves past them from June 17 to 19 and July 15 to 17. Mercury remains in Gemini in June; Venus retrogrades from Gemini to Taurus; Mars, Jupiter, and Saturn are in Leo; Uranus is in Libra; Neptune in Ophiuchus; Pluto in Bootes. The sun moves from the constellation Taurus into Gemini.

June 1: Mercury is quite close to Venus tonight.

June 11: The daytime occultation of Aldebaran is above the horizon along the West Coast.

June 14: Mercury, near the moon tonight, is at greatest easterly elongation, well placed as an evening star.

June 15: Venus, in inferior conjunction, becomes a morning star.

June 17: The moon is quite close to Regulus tonight. Jupiter, Mars, and Saturn are to its left.

June 18: The moon is between Jupiter and Regulus, to its right; Mars and Saturn, to its left.

June 21: The sun is at the summer solstice at 12:47 A.M., EST.

June 25: Mars passes from right to left of Saturn.

June 27: Mercury begins retrograde (westerly) motion.

July 5: Earth is at aphelion, farthest from the sun, 152,100,000 kilometers (94,500,000 miles) distant.

July 9: The daytime occultation of Venus occurs above the horizon in North America.

July 11: Mercury, in inferior conjunction, becomes a morning star.

July 15: An early evening occultation of Jupiter occurs above the horizon in western North America.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those you see in the sky. When you turn to face in other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match stars in the sky with those on the lower half of the map. The map represents the evening sky at about 11 to 12 P.M. on June 1; 10 to 11 P.M. on June 15; 9 to 10 P.M. June 31; and 8 to 9 P.M. on July 15. Only planets and moon phases above the horizon at those times are shown. All times are EST.

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers… rain forests, mountains, and tundra … seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

# Afterworlds in the Attic

No one really knows exactly how many artifacts are in the anthropological collections of the American Museum of Natural History. But whatever the number, they fill to overflowing some fifty storage rooms, vaults, and attics scattered throughout the Museum's twenty-two buildings. The physical objects, however, constitute only a portion of the entire collection. In the past 111 years, Museum ethnographers have assembled another kind of collection that is, in a sense, invisible. It has no catalog numbers, is not cross-referenced, and has no monetary value. It cannot be displayed, photographed, or insured.

This collection is a vast body of myths, songs, dreams, and visions garnered from hundreds of living and extinct cultures from New Guinea to Manhattan Island. Both in published works and in reams of unpublished notes stored in a fifth-floor vault, one can find hundreds of creation myths, descriptions of afterworlds, epic tales of gods, humans, and demons, magical formulas, dreams, songs, and chants. Hidden among these books and papers is a version of the creation of man from the Hackensack Indians of Staten Island, along with accounts of the dream cults of the Oglala Sioux and shaman chants of the Tsimshian. Here too one can read the European-influenced epics of the San Carlos Apache, the love poetry and death songs of the Ojibwa, and dozens of myths of the Great Flood and stories of the golden age when animals spoke like people.

According to David Hurst Thomas, chairman and curator of the Department of Anthropology, no one has any idea of just how much—or what—mythological material might be stored in the Museum. "The Museum," he says, "hasn't consciously compiled and sorted the material. All I can tell you is that there's a hell of a lot of it. But it's the kind of thing that falls through the cracks, if you know what I mean."

Thomas explains that the Museum gathered most of its mythological material before 1930. Today, with a few exceptions, Museum ethnologists are less interested in mythology, partially because many of them are working in "literate" societies, where myths are written down. One of the exceptions is Robert Carneiro, a curator specializing in the cultures of Amazonia. In a visit to South America in 1975, he collected a dozen myths from the Kuikuru, a Carib-speaking people who live in a single village in the upper Xingú basin of central Brazil.

By far the most complete body of myths collected by the Museum has come from the Indian cultures of North America. Between 1880 and 1930, assiduous myth collectors traveled west with pen and paper to capture the Indian myth cycles before they became hopelessly garbled by

Christian influences. While Franz Boas was busy recording the entire mythological system of the Kwakiutl in the original Kwakwala, first for the Museum and later for Columbia University, his contemporary Robert H. Lowie was tramping across the West from Alberta to Arizona, collecting hundreds of myths (as well as artifacts) from the Hopi, Assiniboine, Blackfoot, Cree, Shoshoni, and Ojibwa cultures. Pliny Earle Goddard, another Museum curator, spent twenty years studying the dancing societies of the Sarsi, the dialects of the great Athabascan family, and the ethnology of the Southwest Indians in general. Clark Wissler, who was chairman of the Department of Anthropology, built the Museum's collection of Indian material into one of the finest in the world and also edited several numbers of the *Anthropological Papers of the American Museum of Natural History*, in which many of the myth cycles were published.

Boas was one of the first anthropologists to recognize the scientific value of myth. In the preface to his *Kwakiutl Culture as Reflected in Mythology* (1935), he wrote that through a people's myths, "a picture of their way of thinking and feeling will appear that renders their ideas as free from the bias of the European observer as possible."

Myth gathering, Boas realized early

HABAND for MEN

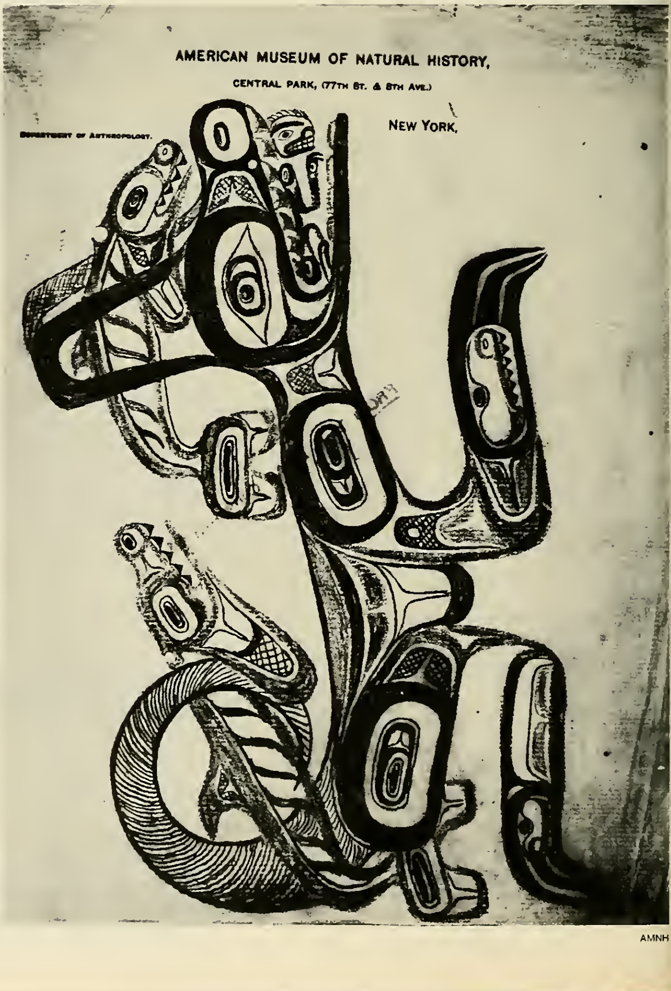
in his career, was not easy, as an entry in one of his early journals attests:

> October 12. I had a miserable day today. The natives held a big potlatch again. I was unable to get hold of anyone and had to snatch at whatever I could get. Late at night I did get something [a tale] for which I had been searching—"The Birth of the Raven". . . . It is especially curious that myth cycles do not seem to be alike among the different tribes speaking the same language, although I am not sure how much of this may be due to my ignorance of the myths.

When Boas was not in the field, his interpreter, George Hunt, agreed to collect and transcribe Kwakiutl myths, for which Boas paid him 50¢ a page. Morris K. Jesup, the first president of the Museum, reimbursed Boas for this worthwhile expense.

Lowie and Wissler faced a different set of problems. Many of the myths they recorded involved lesbianism, necrophilia, bestiality, coprophagy—subjects that would have shocked a culture only recently emerged from the Victorian Age. The Museum, following a standard practice, solved the problem of publishing this material by translating the sensitive passages into classical Latin, which, presumably,

*Apparently Boas had run out of blank paper and had to use a piece of American Museum stationery for this drawing of the mythological sea wolf with two killer whales sporting behind its back.*



AMERICAN MUSEUM OF NATURAL HISTORY,
CENTRAL PARK, (77TH ST. & 8TH AVE.)
DEPARTMENT OF ANTHROPOLOGY.
NEW YORK,

AMNH

only an erudite and dedicated scholar could decipher. The result was often an odd mixture of languages:

> "Lignum Mentulae Vice Fungens"
> A hunter heard someone laughing. Prope risores cum advenisset, duas mulieres conspexit quae ridentes ligno pro mentula utebantur. The woman caught sight of the man and broke the piece of wood ita ut utrius—que earum vulvae dimidium haereret.
>
> —Assiniboine, 1907

In other texts, Museum authors and editors prepared a carefully censored and circumspect translation for the beginning of the paper and put the undoctored text at the end as a word-by-word, unsyntactical translation next to the original Indian text.

Since the 1930s, the Museum gradually shifted its focus from myth collecting and interpretation to other aspects of human culture. Myth, however, will continue to fascinate and attract anthropologists. "I became interested," says Robert Carneiro, "in the Kuikuru myths as narratives, almost on a subscientific level." Gathering the myths of the Kuikuru turned out to be easy. Unlike some groups who delight in lying to anthropologists (who, after all, are an ideal target), the Kuikuru are truthful and do not feel that myths and beliefs are secret knowledge to be guarded from outsiders. Carneiro was able to find several older informants who knew a great deal about myth, the soul, and the afterworld and who were happy to have an attentive audience.

Among the Kuikuru, the learning and transmission of myths and beliefs is a casual matter. "Now and then," says Carneiro, "someone will tell a myth and those who want to listen will gather around. But there is no concerted effort to teach the young the mythology, and some adults don't know the myths and aren't particularly interested."

Carneiro feels the study of myth has its limits. "I tend to be skeptical of efforts to interpret myths. And to think you can decipher the basic nature of the human mind from myth—as in the work of Lévi-Strauss—strikes me as going too far." Myths, Carneiro feels, are in some respects much like material objects and can be a means of elucidating relationships between cultures. "If we had," he explains, "a full corpus of myths from every tribe in Amazonia, we could reconstruct contacts and influences."

Of the dozen or so myths Carneiro collected, one is in press, and the rest he hopes to publish together in the *Anthropological Papers of the American Museum of Natural History.*

The Museum's collection of myths may turn out to be as valuable and irreplaceable as its physical collections. Artifacts can survive the extinction of a culture: pots, house foundations, knives, stonework, and burials will last for thousands of years. The myths of a nonliterary culture, however, are perhaps its most delicate artifact and are the first to disappear in the face of change or destruction. It was perhaps with this thought in mind that Franz Boas addressed the Kwakiutl in 1897 with the following words:

> Friends, I am Mr. Boas who is speaking to you. I am he whom you called Heiltsaqoalis. It is two winters since I have been with you, but I have thought of you often. . . . I am sorry to see how many of your children . . . walk the ways of the white man. The ways of the Indian were made differently from the ways of the white man at the beginning of the world, and it is good that we remember the old ways . . . your young men do not know the history of your people . . . it is not good that these stories are forgotten. . . .

*Many Northwest Coast myths invol the duality of the world. In this illustration, a thunderbird, a symbol of the upper world, rides on the back of a killer whale, symbolic of the lower world. The growing influence of Europeans on Northwest Coast peoples is evident in the perspective rendering of the bird's wings, which would have been drawn full front in precontact times.*

AMN

**Objects of Bright Pride**

The Membership Office is presenting a special members' series, *Native Americans of the Northwest Coast*, on two Wednesday evenings, June 18 and 25 at 7:30 P.M. in the Auditorium. The first program will feature Edward S. Curtis's *In the Land of the War Canoes*, filmed in 1914, with a Kwakwala-language soundtrack added in 1973. Bill Holm, who produced the soundtrack, will introduce the film and answer questions from the audience.

The second program, *Objects of Bright Pride: The Formation of a Great Collection*, will be a lecture by Alan Wardwell on the formation of the Museum's collection of Northwest Coast art, judged by many to be the largest and finest in the world. The lecture will include slides of artifacts, and nineteenth-century transparencies of the Northwest Coast taken during expeditions there. Wardwell is director of the Asia House Gallery and curator of *Objects of Bright Pride*, an exhibition of Northwest Coast art from the Museum collection now on display at the Center for Inter-American Relations in New York. The programs are free to members, $3.00 each for nonmembers.

**Discovery Tours**

In June 1980, twenty-five friends of the Museum will join Kenneth A. Chambers, lecturer in zoology at the Museum, for a three-week *Alaska Wildlife Adventure*. The trip will explore several different habitats in search of wildlife. At Glacier Bay, where glaciers meet the sea, tour members will observe hair seals and whales amidst newly created icebergs. In Mount McKinley National Park, tour participants will search for mammals and birds in the wildflower-covered tundra at the base of the Alaska Range and Mount McKinley. Tour members will fly across the Bering Sea to the Pribilof Islands, where more than a million fur seals and countless rare cliff-nesting birds can be found. Write to Discovery Tours for more information about the *Alaska Wildlife Adventure* and other 1980 and 1981 tours.

**Shadow of Vishnu**

Puppeteers, musicians, storytellers, shadow puppet artists, and others from India will present ten performances of traditional puppet theater June 17–22. The maharajah of Sawantwadi will introduce and explain the troupe. The puppets—some beautiful, some grotesque—represent gods and demons, heroes and villains, and other mythical characters featured in the ancient Indian epics. Write to the Department of Education at the Museum for more information.

**Imaginary Worlds**

Twenty watercolors by artist Sonja Eisenberg are currently on display at the Hayden Planetarium. Eisenberg, who has had showings in New York, Paris, Amsterdam, and other cities, paints visions of imaginary worlds. The show, entitled *New Horizons*, will continue through June 16.

**Aztec Theater**

The Touchstone Center, known for its unusual theatrical productions based on anthropology, will present *My Music Reaches to the Sky*, a piece about an Aztec myth. The free performance will take place in the Education Hall on Saturday, June 14, at 1:00 and 3:00 P.M.

**Northwest Coast Film Series**

On June 7 and 8, the Department of Education is presenting films on the Indians of the Northwest Coast. On Saturday, June 7, four films exploring traditional Northwest Coast art and culture will be shown in the Auditorium between 2:00 and 4:20 P.M. Included will be anthropologist Franz Boas's 1930 film, *The Kwakiutl of British Columbia*, made on his last trip to the Pacific Northwest. On Sunday, June 8, between 2:00 and 4:00 P.M., two films will deal, respectively, with Indian photographer Edward S. Curtis and the mythology of the totem pole. All films are free.

*"For one brief shining moment that was known as Camelot."**

# The Romance of Camelot

## PORCELAIN BELL COLLECTION

*Twelve beautiful collector's bells in fine bone china, decorated with 24kt gold . . . a captivating adornment for any room in your home.*

**A Limited Edition.**
**Advance deadline: June 30, 1980.**

---

CAMELOT . . . what visions the name alone conjures up! Of chivalrous knights and lovely ladies. Thrilling adventures and gallant quests. Of royal banners, magic swords and shields of honor. Of opulent feasts at the Round Table. Of secret love potions. Of King Arthur and his Guinevere, Lancelot and Elaine, Sir Galahad, Merlin the magician, and the mysterious Lady of the Lake.

The legends of Camelot have been told and retold over the years in works of art, music and literature. But never so brilliantly as in Alfred Lord Tennyson's romantic poem, *Idylls of the King*. And now—a century after it was written—this masterpiece has inspired the creation of a new work in a treasured collecting tradition: *The Romance of Camelot Porcelain Bell Collection*.

To create the original works of art for these collector's bells, Franklin Porcelain has commissioned the eminent European artist Giani Benvenuti. He is a master of design—able to create within a small space an extraordinary profusion of intricate detail. And his colors have a jewel-like brilliance that brings to mind the precious illuminated manuscripts of medieval times.

**Richly detailed . . . illuminated with color . . . finely crafted in bone china**

The works Benvenuti has created portray the most enchanting moments from the stories of Camelot. The Lady of the Lake presenting the bejeweled sword Excalibur to young Arthur . . . the vision of the Holy Grail appearing to Sir Galahad at the Round Table . . . Gareth gallantly fighting the blue knight Morning Star . . . the mortally wounded King Arthur sailing away from Camelot on a barge attended by three queens . . . Twelve unforgettable episodes—twelve magnificent porcelain bells.

The quality of detail achieved by the artist is remarkable. The tiny ripples on the surface of the lake. The battlements of a distant tower. The intricate mesh of chain mail armor. The gold-work of a gown. The embroidery of a veil . . . Each work of art is both precise and superbly executed. The colors are clear and pure, and the translucence of the white bone china is a lovely background for the original Camelot designs. Then, to add a special note of elegance, each porcelain bell is *decorated with pure 24 karat gold*.

**Available for a limited time only**

In the tradition of fine works in porcelain, *The Romance of Camelot* will be available only during a single year. Furthermore, the collection is being offered only by subscription and only from Franklin Porcelain. In addition, there is a further limit of one collection per person. Thus, the total edition will be forever limited to the exact number of individuals who place valid subscriptions during the year 1980. Thereafter, this collection will never be made available again.

The Camelot bells will be sent at the rate of one every other month, and the issue price of $22.50 for each bell may be paid in two monthly installments of just $11.25 each. A Certificate of Authenticity will accompany the collection.

To subscribe, please mail the application below to Franklin Porcelain, Franklin Center, Pennsylvania, by the advance deadline of June 30, 1980.

MR. PEALE'S MUSEUM, by Charles Coleman Sellers. *W. W. Norton and Co., $14.95; 370 pp., illus. A Barra Foundation book.*

Recently a friend of mine visited the Grand Canyon. He told me that he had not been tremendously stirred by the experience, but that the expression on the face of his dog as it peered into the abyss was worth the price of the trip. Reading *Mr. Peale's Museum* I was reminded again of how much of our ability to marvel has been lost and in what a short time. It is not quite a hundred and eighty years since Charles Willson Peale undertook this country's first organized scientific expedition for the purpose of exhuming "The Great American Incognitum"—the bones of what proved to be a mastodon discovered in a marl pit on a farm near Newburgh, New York. The event caused national excitement. President Jefferson offered the army's help to get the bones out of the water-filled pit, but improvisation and invention came naturally to Peale. He devised his own ingenious machinery—a wheel turned by the leg power of eager volunteers brought up buckets of water and drained the pit at the rate of 1,440 gallons of water an hour. Peale later wrote in his diary, "The Vice President [Aaron Burr] and a considerable number of Ladies and Gentlemen came to see the Bones . . . . The news of them must have blew like wild fire, for upwards [of] 80 persons . . . came that evening."

When Peale exhibited the mounted skeleton in his museum in Philadelphia in 1801, the creature was hailed as the "largest of terrestrial beings," and the ninth Wonder of the World. The word "mammoth" burst into the language as "atomic" has in our day. A Philadelphia baker sold "mammoth bread." In Washington a "mammoth eater" consumed forty-two eggs in ten minutes, and a Massachusetts committee sent President Jefferson a "mammoth" cheese that weighed 1,230 pounds. Visitors thronged Mr. Peale's museum to view the giant bones ("every evening illuminated by lamplight until 10 o'clock") and must have shivered with wonder and excitement as they read a handbill describing the animal in life. According to Indian legend, "the Pines crashed beneath their feet; and the Lake shrunk when they slaked their thirst . . . . Forests were laid waste at a meal . . . . " What an animal! What a thrill to see it for the first time! It is impossible not to envy those spectators whose sense of the marvelous was still virgin and intact.

The museum was the creation of Charles Willson Peale, born in 1741, nine years younger than George Washington. Washington visited the museum and contributed two Chinese golden pheasants, which Peale preserved and mounted. "I was richly repaid in being able to preserve so much beauty. Before this time I had thought those birds . . . seen in Chinese paintings were only works of fancy." Two hundred years ago even a pheasant was still a marvel.

When Peale began collecting for his museum in 1784 he was in his forties, a veteran of the Revolution, and an established portrait painter, but painting barely supported his growing family. A commission to sketch a collection of gigantic bones—the great scientific mystery of their time—led to the thought of a museum to display similar objects and bring together examples of everything—animal, vegetable, and mineral—that makes up the natural world. To house it, Peale added rooms to his existing portrait gallery and announced in the newspapers that "Mr. Peale . . . will make a part of his House a repository for Natural Curiosities." His appeal for donations of specimens brought them by the wagonload. A stable next door was converted into a zoo where living specimens—from cougars to rattlesnakes—awaited immortality. The enterprise was a remarkable home industry. Peale, helped by his sons and daughters (of which there would eventually be ten), tirelessly collected, experimented with preservatives (DO NOT TOUCH THE BIRDS. THEY ARE COVERED WITH ARSNIC POISON, read a sign), painted appropriate watercolor backgrounds, and devised natural habitat effects of a kind that are standard today but were then a controversial innovation.

Charles Coleman Sellers's biography of the museum (he has already written Peale's) makes clear that the enterprise was a labor of love, vision, and idealism that absorbed Peale's enormous energies and talents for the latter half of his long life. There had been nothing quite like Peale's museum in the world before. Contemporary collections were starkly scientific or else popular grab bags of curiosities. Peale, implementing Rousseau's ideal of teaching as a sublime ministry, designed his museum to attract, delight, and inform all comers. In an address appealing to Philadelphians for finan-

cial support, Peale described the object of his labors thus:

> To diffuse a knowledge of the wonderful works of creation, not only of this country but of the whole world. Also to show the progress of arts and science, from the savage state to the civilized man . . . . To form a school of useful knowledge, to diffuse its usefulness to every class in our country, to amuse and in the same moment to instruct the adult of each sex and age . . . did I exert every nerve by increasing labors . . . . By day and by night, as long as I could keep my eyes open, did I labour to preserve animals, common as well as those rarely met with.

Peale's belief that persons of each class, sex, and age deserved equal access to instruction was yet another of his innovations. "The birds and beasts will teach thee!" was the promise Peale printed on admission tickets that cost twenty-five cents. That the teaching might be accurate he adhered to strict Linnaean order. Of his natural history displays, his bird collection was the largest and most beautiful, and his friend Alexander Wilson based his *American Ornithology* on it, but there were also mammals, insects, fishes, minerals, and artifacts from all corners of the globe. In its heyday the museum more than fulfilled the founder's early vision.

In his old age Peale painted a portrait showing himself lifting a red velvet curtain to reveal an almost endless gallery beyond. One hand raises the curtain with a proud flourish while the other beckons the viewer to enter. The end of Peale's story gives poignancy to that beckoning gesture. From the beginning he envisioned his museum becoming a great national institute, cherished and enhanced by those who came after him. He believed that "in some future day [the musuem] will be the admiration of the world," and repeatedly begged politicians and city fathers to take it over and ensure its survival with public funds. President Jefferson thought it would be unconstitutional. The legislature thought it too expensive. Peale's offer was never accepted. After his death in 1827 at the age of eighty-six, the museum endured for another fifteen or so years, during which his many heirs struggled to wring a living from it. When they failed, P.T. Barnum gobbled up much of the contents and lost them in disastrous fires. What bits survive are mainly at Harvard, doubly valuable as mementos of an inspired lifework to which much is still owed as forerunner of the great natural history museums of today. Ironically, as Peale's museum was being dispersed, politicians were debating how best to use English scientist James Smithson's bequest "for the increase and diffusion of knowledge among men." In 1869, twenty-three years after the founding of the Smithsonian Institution, the American Museum of Natural History was chartered and would become the foremost example of Peale's ideal.

Charles Coleman Sellers, Peale's great-great-grandson, has written a book that is clearly a labor of love, filled with facts that would elsewhere be mere footnotes to history. Gathered together, they bring the reader a haunting sense of Mr. Peale's times—an era when the natural world was still inexhaustibly marvelous and numberless "wonderful works of creation" waited to be explored for the enjoyment and enlightenment of all.

*Faith McNulty is on the staff of* The New Yorker, *in which her articles on whooping cranes, whales, and other animals have appeared. A collection* —The Wildlife Stories of Faith McNulty—*will be published in October by Doubleday and Co.*

*Charles Willson Peale lifts a curtain to reveal his newly incorporated museum in this self-portrait painted in 1822.*

**Pocket Gophers** (p. 36)

Short, readable descriptions of all kinds of pocket gophers can be found on pages 244–53 of *The Mammals of Eastern United States*, volume 2, by W. J. Hamilton, Jr. (New York: Macmillan Publishing Co., 1963). “Florida Pocket-Gopher Burrows and Their Arthropod Inhabitants,” by T. H. Hubbell and C. C. Goff (*Proceedings of the Florida Academy of Sciences for 1939*, vol. 4, August 1940, pp. 127–66), gives background on the creatures that share the pocket gopher's burrow. “Goff's Pocket Gopher,” by L. M. Ehrhart, in *Rare and Endangered Biota of Florida*, volume 1, edited by J. N. Layne (Gainesville: University Presses of Florida, 1978, pp. 1–52), provides more recent data. Two specialized articles are “Mound Building by Pocket Gophers (Geomyidae): Their Impact on Soils and Vegetation in North America,” by H. W. Mielke (*Journal of Biogeography*, vol. 4, 1977), and “Reproduction in the Pocket Gopher in North-central Florida,” by E. S. Wing (*Journal of Mammalogy*, vol. 41, 1960, pp. 35–43).

**Caterpillars** (p. 42)

The original work referred to in “Artful Diners” is described in two scientific papers by B. Heinrich. “The Effect of Leaf Geometry on the Feeding Behaviour of the Caterpillar of *Manduca sexta* (Sphingidae),” published in *Animal Behaviour* (vol. 19, 1971, pp. 119–24), discusses behavior that is nonspecific and equally adapted to a variety of leaf shapes. “Foraging Strategies of Caterpillars: Leaf Damage and Possible Predator Avoidance Strategies” (*Oecologia*, October 1979, pp. 325–37) provides many pictures of variously chewed leaves and concludes that “some caterpillar foraging behaviors may have evolved under the selective pressure of visually oriented predators that use leaf damage as a cue in their searching behavior.” H. B. Cott's *Adaptive Coloration in Animals* (London: Methuen and Co., 1940) is a review of the literature on adaptive coloration and behavior in all kinds of animals, including caterpillars. *Defence in Animals* (New York: Longman, 1975), by M. Edmunds, picks up where Cott leaves off. A summary of recent literature on the evolution and effectiveness of color and other antipredator defenses and predator-prey relationships, this book's bibliography directs the reader to original research papers, books, and review articles. *Animals and Their Colors*, by M. and P. Fogden (New York: Crown Publishers, 1974), presents these subjects for the lay reader and includes a bibliography, a glossary, and color photographs on almost every page. A. J. Alexander describes her work on heliconiid larvae in “A Study of the Biology and Behavior of the Caterpillars, Pupae and Emerging Butterflies of the Subfamily Heliconiinae in Trinidad, West Indies” (*Zoologica*, April 28, 1961, pp. 1–24). Two *Natural History* articles of interest are “Investigations into Mimicry,” by L. P. Brower and J. V. Z. Brower (April 1962, pp. 8–19), and “Mimicry: The Deceptive Way of Life,” by M. Rothschild (February 1967, pp. 44–51).

**Hail** (p. 54)

*Cloud Physics and Cloud Seeding*, by L. J. Battan (Westport: Greenwood Press, 1979), originally published in 1962 as part of the Science Study Series, discusses hail, ice crystals, rain, snow, clouds, cloud and hailstorm modification, and simulated rainfall. Also intended for the general reader, *Hailstorms of the United States*, by S. D. Flora (Norman: University of Oklahoma Press, 1956), focuses more on damage done by hail and on man's efforts to predict storms. In “The Paradox of Hail Suppression” (*Science*, January 14, 1977, pp. 139–45) D. Atlas, former director of the National Hail Research Experiment, explains how cloud seeding can either increase or decrease the amount of hail. *Hailstorms and Hailstone Growth*, by N. R. Gokhale (Albany: State University of New York Press, 1976), is a comprehensive, technical account of modern hail research.

**Wolves** (p. 58)

*The Wolves of Mount McKinley*, Fauna Series No. 5, by A. Murie (Washington: U.S. Government Printing Office, 1944), a readable account of the biology and ecology of the Alaskan wolf, is the result of a two-year field study of the relationship between timber wolves and Dall sheep, with notes on other animals. L. D. Mech's *The Wolf: The Ecology and Behavior of an Endangered Species* (Garden City: Natural History Press, 1970) is for the scientist and the general reader. The author's rich field experiences, combined with the established data, make this an interesting, well-documented volume. *Of Wolves and Men*, by B. H. Lopez (New York: Charles Scribner's Sons, 1978), concentrates on the wolf in the folklore and literature of different cultures. Most of the May 1967 issue of *American Zoologist* is devoted to the ecology and behavior of wolves. The issue includes “Numbers, Turnover, and Social Structure of the Isle Royale Wolf Population,” by P. A. Jordan, P. C. Shelton, and D. L. Allen (pp. 233–52). Points raised in this article are explored further in “Continued Studies of the Status, Socialization, and Relationships of Isle Royale Wolves, 1967–70,” by M. L. Wolfe and D. L. Allen (*Journal of Mammalogy*, vol. 54, no. 3, 1973, pp. 611–35). R. J. Rutter and D. H. Pimlott's *The World of the Wolf* (New York: J. B. Lippincott Co., 1968), is a profusely illus-

## ditional Reading

trated introduction for children that includes the authors' personal observations. Two *Natural History* articles are "The Social Organization of Wolves," by J. H. Woolpy (May 1968, pp. 46–55), and "Why Some Deer Are Safe From Wolves," by L. D. Mech (January 1979, pp. 70–77). Write to the North American Wolf Society, P.O. Box 118, Eatonville, WA 98328, for a list of books, pamphlets, and government publications on wolves. This society publishes a quarterly journal and sells reprints of its articles.

**Climate** (p. 64)

For a more complete treatment of climatic change and paleoclimatology, see *Climates of Hunger: Mankind and the World's Changing Weather*, by R. Bryson and T. Murray (Madison: University of Wisconsin Press, 1979). E. Le Roy Ladurie's *Times of Feast, Times of Famine: A History of Climate Since the Year 1000*, translated by Barbara Bray (Garden City: Doubleday and Co., 1971), is an outgrowth of the author's research into the history of agriculture in Europe. *Climates of the Past: An Introduction to Paleoclimatology*, by M. Schwartzbach (New York: AMS Press, 1977), first published in 1963, is a general text, while *Descriptive Paleoclimatology*, edited by A.E.M. Naun (New York: John Wiley and Sons, 1961), is a more technical symposium. R. Carpenter discusses the impact of climatic change in *Discontinuity in Greek Civilization* (New York: W. W. Norton and Co., 1968). "Climate of the Central North American Grasslands," by J. R. Borchert (*Annals of the Association of American Geographers*, vol. 40, 1950, pp. 1–39), and "A Pre-Columbian Urban Center on the Mississippi," by M. L. Fowler (*Scientific American*, August 1975, pp. 92–102), are specialized articles.

TIRED OF BUYING JUNK?
GET A Carpet Cat®

The CARPET CAT is built with care by people who make nothing else, for people who believe household appliances should last a lifetime. We also think appliances should be noiseless, convenient, pretty, efficient and require no electricity.

If you feel the same way, you're going to love a non-electric CARPET CAT floor and carpet sweeper. We believe it is the lightest, strongest, most efficient and convenient appliance of its type on earth. In the past 6 years, thousands of commercial users worldwide (airlines, hotels, restaurants, etc.) have confirmed our belief by demanding only our floor sweepers. A CARPET CAT weighs under 3 pounds, is only 9 inches wide and works as well on a bare floor as it does on carpet. It picks up sugar, sand, pet hairs, paper clips, ashes and much more. Who really needs a vacuum cleaner?

Yes, it looks like an old-fashioned "carpet sweeper" (except it is far smaller and about ⅓ the weight), but there the similarity ends. The CARPET CAT is patented and based on entirely new technology. Its natural hog bristle brush will outlast synthetics by about 3 to 1. It should last a lifetime if properly cared for in ordinary household use. The CARPET CAT'S baked enamel surface wipes clean with a damp cloth. Horse hair corner brushes clean right up to the wall, and the whole sweeper can be hung up in 2 inches of wall space. EVERY PART IS REPLACEABLE AND CARRIED IN STOCK.

If you can find any other sweeper that can make the above claims, BUY IT. We are sure you can't, so we want you to try our CARPET CAT.

Pick up unexpected messes in seconds.

Clean stairs quickly and easily.

Reach hard-to-get-at-places.

THE CARPET CAT: *Only* $24.95 plus $3.50 for ship./hand.

NO NOISE, NO HOSE, NO ELECTRIC CORDS

Carpet Cat

30-DAY MONEY-BACK GUARANTEE
If you decide the CARPET CAT is unsatisfactory FOR ANY REASON, simply return it to us within 30 days and we will refund the entire purchase price. You can't lose. DORSAY, 142 MacArthur Ave., Dept. 430, Garfield, N.J. 07026

## Travel

### Sri Lanka's PERAHERA
**Festival of the August Moon**

*Join a special tour to Asia's most spectacular celebration honoring the Sacred Tooth Relic of the Buddha. A hundred elephants, dancers, drummers, temple bells, the cracking of whips, blazing torches that light a myriad gems create the stunning pageantry of the Kandy Perahera.*

*You also tour the countryside to see ancient cities in the interior, the hill country, coastal villages, spice gardens, tea estates and craft centers. Extensions to the mountain valley of Kashmir and to the temple cities of South India are available.*

*For information please contact:*

All photographs taken by Adelaide de Menil at Allen's Neck Clambake

# An Original Old-fashioned Yankee Clambake

*Tradition is alive and well in New England!*

**by Raymond Sokolov**

The most exclusive and elaborate event in the American culinary calendar takes place on a tree-lined plot of land near Dartmouth, Massachusetts, in August. Last year, Wilfred Morrison, the proprietor of Davoll's General Store in the nearby hamlet of Russells Mills, was the *chef de cuisine*. He presided over a brigade of more than one hundred *sous-chefs*, who had worked for days to get this multicourse extravaganza onto the plates of five hundred lucky guests, who had signed up in time to secure a seat at one of the long wooden picnic tables across the path from Morrison's alfresco kitchen. Two thousand eager gourmets were turned away.

Unlike most modern chefs, Morrison did not cook with gas on a massive professional range. Indeed, he had no range at all, but insisted on a traditional, one might even say aboriginal, oven constructed, *à l'improviste*, from rocks, wood, and canvas. No wire whisks, copper pans, or Cuisinarts were allowed on the premises, only the canonical utensils sanctified by ninety previous years' experience: long-handled steel shovels.

The Allen's Neck Clambake began as an outing for the Sunday school of the local Quaker meeting in 1888. Originally held on Horseneck Beach, it moved slightly inland after 1903, but it is still within smelling distance of the Massachusetts shore in the state's biggest surviving agricultural region, just

to the east of the Rhode Island line. Getting lost in the maze of winding country roads running around farms is inevitable the first time you visit the area. The rational highway system of modern America is only minutes away, but just far enough to preserve the area from creeping exurbia. And because of this isolation from the socioeconomic mainstream, the life of the region has been spared the worst, most deracinating shocks that have shaken much of the rest of New England. A community of dirt farmers and gentry with a conservative outlook is holding its own on the east branch of the Westport River. And the Allen's Neck Clambake is its high-water mark, a historic ritual that transcends its official purpose of raising funds for the Friends Meeting House.

When working folk and local Brahmins sit down side by side over paper plates filled with steaming clams and ears of corn redolent of rockweed, there is a spirit of oldtime, small-town democracy in the salt air, the same spirit that once animated town meetings in New England. Perhaps the mood is mainly symbolic, but at least the symbolism is pure and unadulterated by slickness, shortcuts, and Chamber of Commerce hoopla. The genius of this clambake is its unremitting, stiff-necked fidelity to a method of cooking and a menu that have not changed since the dawn of the Republic, when settlers learned to cook the corn and shellfish of their newfound land in ad hoc ovens the Indians had invented and perfected on the rocks and sand of that same coast.

The New England clambake has as much claim to the title of our national feast as Thanksgiving, except that Thanksgiving flourishes everywhere, while the clambake has mostly fallen into neglect and been distorted by modern notions. Even some of the clambake's most devoted adherents will succumb to the proddings of their sensual natures and embellish the bake with lobsters. Others, hoping to simplify the cumbersome, labor-intensive

rocess of watching and controlling he bake, conduct this chthonic cookry in a metal prison that started out s a washtub.

At Allen's Neck, the bakemaster as always held the line against lobster ancification. And teams of willing veed-rakers and rock-pilers have been urning out early and late for more han fourscore years. This combinaion of abundant manpower and a menu codified right down to the tripe see recipe) has preserved the original Yankee clambake in as rugged and ristine form as modern conditions will allow.

Today, it is true, the menfolk no longer sail a catboat into Buzzard's

GRANDMA'S MOLASSES

Bay for fresh fish. And clams are no longer dug locally. The fish (mackerel) comes already filleted from a wholesaler. Clams arrive from Maine, where they were dug commercially in Machias Bay. But the corn is picked in a local field the morning of the bake. And the process of the clambake itself is militantly unchanged.

On the eve of the bake last summer, some twenty volunteers, men and boys, waded into the east branch of the Westport, collecting rockweed under the watchful eye of Karl Erickson, a retired schoolteacher with twenty years' experience on the clambake committee. He picked up a handful of rockweed and pointed out the blisters all over it. "They're full of water," he explained. "When they're heated, that water makes our bake into a natural steam pressure cooker."

It was almost nightfall before the pickup truck on the riverbank was full of rockweed. Meanwhile, other volunteers had been gathering the rocks and the hardwood for the fire.

By 7:15 A.M. the day of the bake, all of the raw materials had been assembled at the site, except for the corn, still to be picked, and the clams, which would soon be laboriously sorted and washed in a boat filled with seawater on the sand at Horseneck Beach.

At the site, a team of teen-agers started building the huge fire. They began with a concrete apron covered with a platform of long green oak stringers, on which were laid alternating levels of cut hardwood and stones. One girl, hefting a granite rock as big as her head and passing it on down the line, said, "This is great. All these years we've been coming here and we never knew this was how it was done."

Eventually, she and her friends had built an oblong rock and wood structure that stood five feet high and measured about twelve feet long and four feet across. There was kindling on top and gasoline-soaked paper underneath. At 8:45 the fire was lit and roared away brightly. "Utopia," said Karl Erickson, "is when it burns so there's not a stick of wood left, just charcoal and stones." By 9:00, all the food was cut and trimmed, bagged and racked, ready to cook. J.T. Smith, 91 years old and a former bakemaster, looked on approvingly.

By 10:45, the fire had burned down to a pyramid of rocks. It was time for the pullers. With their long-handled shovels, they dragged the hot rocks off the cement apron so that the charcoal and ash could be cleaned away. No wood smoke should defile the bake.

Speed was crucial so that the rocks wouldn't cool any more than absolutely necessary. As soon as the cement was clean, back went the rocks. On top of them came the rockweed. The food was set out in layers on the rockweed: the racks of clams first, the delicate corn last. Then the whole sizzling pile was covered with a soaked sheet and six layers of canvas; the edges of these cloths, where they met the ground, were caulked with rockweed. Clouds of vapor rose when the sheet went on, but the extra canvas shrouding and the rockweed sealed in the steam. The last edge was tamped down at 11:45. Twenty minutes later,

## First stop, Guatemala City:

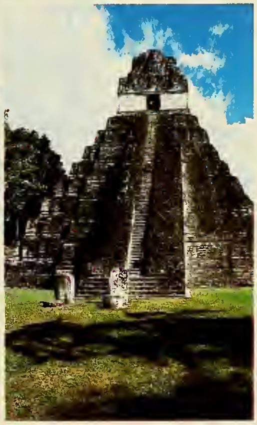
The modern capital, and headquarters for your visit. Great sightseeing, restaurants, shopping and nightlife. Home of the beautiful and ornate National Palace, with its colorful murals of the country's history and mythology. Visit nearby Kaminal-Juyu—the Mayan "valley of the dead."

## Antigua, the Spanish Colonial Capital:

One of the finest examples anywhere of a Spanish colonial city, Antigua was founded in 1543 as the Spanish capital of Central America. Today, the city, declared "Monument of the Americas," is preserved by law in its colonial splendor. Attractions include the palace of the Captain's General and many native artisan shops throughout the city.

## Scenic Lake Atitlan:

Ringed by mountain peaks and volcanoes, Atitlan sparkles like a blue diamond. Enjoy swimming, water sports, fishing, riding and boat trips to quaint villages. One of the most beautiful settings in the world.



## Chichicastenango:

Central America's most famous market. Each Thursday and Sunday, nearly 10,000 Indian artisans gather to show their wares, from food and wooden masks, to pottery, jewelry, blankets and leather goods. You'll be amazed how much a dollar buys.

## Tikal:

Here, the Mayan civilization flourished nearly 2000 years. By 950 A.D. the city had been abandoned. Six square miles of ruins are open, including the legendary Temple of the Great Jaguar.

## Dollar for dollar, today's biggest vacation value. Make this your year to enjoy

# GUATEMALA

**7 Nights from $99 to $176.** (IT9EA1GUATEW)

Take the value vacation: Guatemala.
Price is per person, double occupancy, and includes airport transfers in Guatemala and hotel accommodations in Guatemala City, Antigua or Lake Atitlan. Optional excursions are available to Chichicastenango, Tikal, Antigua and Rio Dulce at additional cost. Air fare is additional. Prices are subject to change and are valid through 12/31/80.

For more information on the many low cost tours of Guatemala, see your travel agent or write:

steam pressure made the canvas billow up taut as a sail in a good wind.

Now Ralph Macomber could rest while the clambake baked. This burly sawyer had supervised the trickiest part of the ritual, the breaking down of the fire and the piling up of the hot stones. And at one o'clock, as 500 eager guests gathered round, it was his job to reach down, pull up a corner of the canvas, and gingerly extract a finger-burning clam. Out of the shell it came, and into his mouth it went. Macomber pronounced it done.

Off came the six canvases and the sheet. Ravenous diners took their places at the tables, and efficient teams of servers moved about, distributing the mountain of food. On my paper plate was a feast without equal. The clams, especially, were remarkable—fresh and tender and permeated with the aroma of rockweed and ocean. I was happy. Wilfred Morrison was happy. Karl Erickson was happy. Ralph Macomber was happy. We stuffed ourselves with an abandon that itself is part of the clambake tradition. The late Skipper Howland, a chronicler of New England life and the grandfather of my host at Allen's Neck, wrote the classic description:

> The first bowl of clams disappears with surprising speed. Another relay appears, reinforced with fish, corn, and potatoes from the bake, and slices of brown bread and helpings of onions from the center of the table. But from this point on how can I attempt to set down in words, which after all are poor things, the disposal of all these gifts of God, which have been for the most part cooked in the good earth, seasoned by the salts thereof, uncontaminated by the impurities of civilization, fresh as the dawn; in such abundance that no one has to bolt his first helping to ensure a second, third, or even a fourth—except to say that, when every soul here gathered has filled himself or herself to comfortable capacity, and those who smoke have ignited the butt ends of Manila cheroots that have come tied in bunches with buttercup-yellow ribbands in leaden chests from the Far Eastern Isles, the day sinks softly and peacefully down toward its end in a pale blue smoky haze of contentment; a contentment that can come only from the know-how of making the most of Nature's gifts and the satisfaction arising from such knowledge, which has been acquired, not from endowed institutions of learning, but from attendance at that greatest of all universities, the outdoor world.

*Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.*

**Clambake to Feed 500 Paying Guests**
**Plus 125 Workers**

(From the *Allen's Neck Friends Cook Book*)

| | |
|---|---|
| | A safe, smooth, convenient site |
| 1 | cord of dry hardwood in 4-foot lengths |
| 1 | truckload of rockweed |
| 1½ | tons of stones about the size of a cantaloupe melon |

All clambakes are not alike; they vary in menu. Allen's Neck always has the same menu:

| | |
|---|---|
| 22 | bushels clams |
| 200 | pounds sausage |
| 75 | pounds fish fillets |
| 150 | pounds tripe |
| 75 | dozen sweet corn |
| 3 | bushels sweet potatoes |
| 30 | pans of dressing |
| 100 | pounds onions |
| 20 | large watermelons |
| 85 | homemade pies |
| 50 | pounds butter |
| | Coffee |
| | Milk |

*Special Requirements*

A group of enthusiastic workers, willing to work from Monday through Thursday; without these people no clambake of this size would succeed.

The clams must be culled and washed in fresh seawater, in a boat at Horseneck Beach.

The sweet corn must be fresh and sweet—harvested the day of the clambake. The rockweed must be fresh and kept moist.

After all the food from the bake has been consumed, it is hard to imagine how 20 large watermelons and 85 pies can disappear, but they do! No person should ever leave an Allen's Neck Clambake unless he or she is "full to the gills."

Now the last, and most important, ingredient of all is to ask our dear Lord for good weather.

## Six-mode exposure control. System versatility. Newer electronics for wider applications.

SHUTTER PRIORITY AE
PROGRAMMED AE
ELECTRONIC FLASH AE
MANUAL
STOPPED-DOWN AE
APERTURE PRIORITY AE

The incredible Canon A-1. It's on the cutting edge of technology, with state-of-the-art electronics and computerized operation.

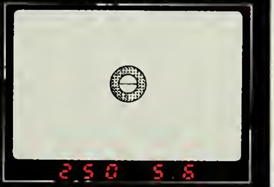
Yet, although the way we build it is complex, the way you use it is the ultimate in simplicity. If push-button-easy fine photography is what you're after, the A-1 can give it to you six ways.

1 Shutter-Priority automation: You pick the speed to freeze or blur action or prevent camera shake, the A-1 picks the perfect aperture automatically.

2 Aperture-Priority automation: Select the aperture you want for a soft background or total overall sharpness, the A-1 will give you the speed that's correct.

3 Programmed automation: On the A-1, this unique exposure mode picks both aperture and speed in ideal combinations depending on the light. You don't have to set *anything*.

4 Stopped-Down automation: This mode lets you get automatic exposure with any lens or accessory you can mount on the camera. Great for astrophotography, photomicrography, close-ups.



5 Flash automation: The A-1 has the easiest electronic flash of any camera of its type. With special Canon flash units, your aperture and speed are set automatically. Just mount the flash, turn it on and shoot for perfect exposures every time.

6 For any type of photography that's not already covered, there's manual.

There's more. Digital control and viewfinder display. Versatile control features. Accessories like a rugged motor drive, compact motorized film winder and interchangeable date/data back. Plus forty Canon FD lenses for unsurpassed image quality and scope.

You won't find another camera like it on the face of the earth. Because only Canon has the technology to make it. Luckily, you don't have to go to the ends of the earth to get an A-1. Only as far as your local Canon dealer.

# NATURAL HISTORY

7/80

The automatic 35mm Minolta XG-1 makes it easy to get clear, sharp pictures. Because the XG-1 sets itself electronically.

So it does the work. And you take the credit.

The XG-1 is compact, lightweight, and comfortable to hold. And its bright viewfinder tells you everything you need to know to take great pictures.

You can add to your fun by adding accessories. Like a Minolta auto winder to advance the film. Or an automatic Minolta electronic flash. And any of the more than forty superb Minolta lenses.

For more information, write Minolta Corporation, 101 Williams Drive, Ramsey, N.J. 07446 In Canada: Minolta, Ontario, L4W 1A4.

Or see your Minolta dealer. And find out how incredibly easy great pictures can be.

# WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE WITH A MINOLTA XG-1.

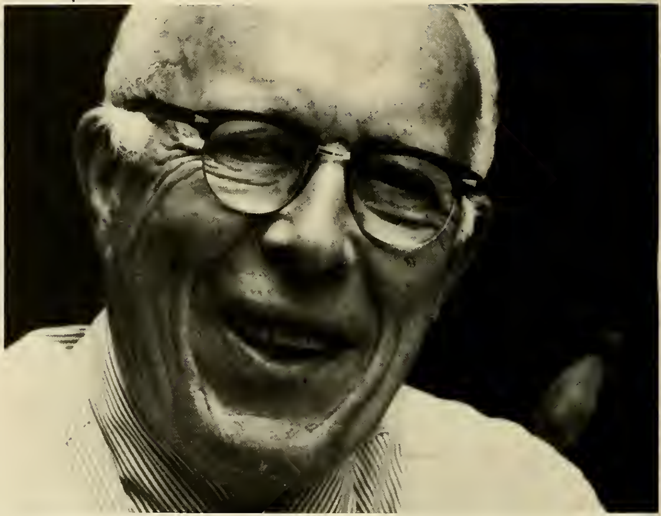
**René Dubos,** a microbiologist whose experimental work led to the discovery of important antibiotics, is equally well known as a successful popular author. Among the fifteen or so books he has written are *So Human an Animal*, for which he received a Pulitzer prize in 1969, and his most recent, *The Wooing of Earth.* Born in a small village in France in 1901, Dubos is a naturalized American citizen. He joined the staff of the Rockefeller Institute (now Rockefeller University) more than fifty years ago. Dubos has received numerous honorary degrees and other awards. He has never lost the constructive approach to problems he expressed in his foreword to *So Human an Animal:* "Man makes himself through enlightened choices that enhance his humanness."



**Niles Eldredge** began his study of the trilobite fossils he writes about in this issue partly by chance. An American missionary who had come to the American Museum of Natural History to have a fossil identified turned out to be a source of thousands of Bolivian fossils. Eldredge, who is investigating the role that species play in macroevolution, describes the essence of his research as trying to reconcile what he was taught with what he "sees in the rocks." He has found that natural selection cannot explain what he saw in the trilobite fossils and suggests some alternatives in his article. Eldredge is a curator in the Department of Invertebrates at the Museum.

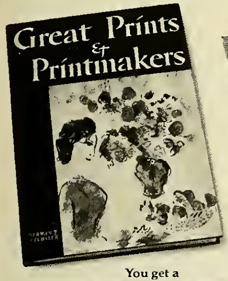
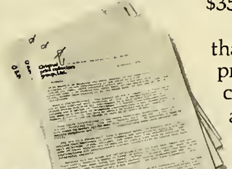
# When we sell you original art, we don't just leave you hanging.



You get a $35 book on original prints. Free.

Certificate of Authenticity

You get a certificate of authenticity and a full money-back guarantee.



You get newsletters with tips on investing in art.

Original print collectors group, Ltd.

You get to browse through beautiful, full-color brochures.

At the Original Print Collectors Group, we do more than sell fine art.

We help you get more enjoyment out of the art you buy.

For example, we help you learn more about collecting. When you buy your first print from us, you get a $35 book on the history of prints and printmaking. Free.

You also start receiving our bi-monthly newsletters that tell you about the techniques used to create original prints. How to care for your prints. Which artists are currently in vogue. And how original prints are doing as investments.

(Many of the prints we sell appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal*, *Business Week*, *Money*, AP, Barron's and UPI have all quoted us as an authority on investing in art.)

Along with the newsletters, you get full-color brochures, which feature our current offerings.

You can browse among signed, limited edition works by Calder, Chagall, Dali, Miró, Picasso and Vasarely. As well as works by up-and-coming artists, all at very reasonable prices.

And if you buy a print, you get a full money-back guarantee. Plus a certificate of authenticity, backed by our reputation as the country's leading dealer in original prints.

Find out for yourself how we help you enjoy the art you buy. Send in the coupon, without obligation.

**Original print collectors group, Ltd.**

**120 East 56th Street, Dept. NH-22, New York, N.Y. 10022**

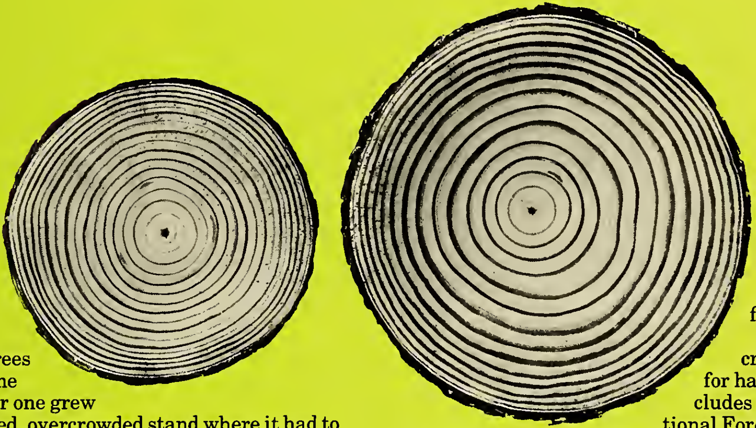
Salmon have been central to the interests of **Anthony Netboy** since 1952. That was the year he joined the Bonneville Power Administration in Portland, Oregon, to report on the problems of hydroelectric development of the Columbia River. He went on to write *Salmon of the Pacific Northwest: Fish v. Dams*, published in 1958. Other books followed as he became caught up in the story of the salmon's fight for survival. He has studied the fish in Europe, Asia, and Alaska, and claims to have visited every country that has, or has had, salmon, except Russia, Korea, and China. A native of Poland, Netboy was a professor of English with the Oregon State System of Higher Education until his retirement in 1971.

Born in Kabul, **Ashraf Ghani** understands the personal dilemmas that current developments have forced upon the educated segment of Afghanistan's population. Basing his account on the lives of people he knows, he has sought to dramatize for *Natural History* readers the perspective of a typical rural schoolteacher. Ghani did fieldwork in Afghanistan from 1973 to 1977, earning a master's degree in political science from the American University of Beirut. Since then he has been working toward a Ph.D. in anthropology from Columbia University; he received his Master of Philosophy this spring. Ghani's present research concerns political developments in Afghanistan from 1747 to 1978, the emergence of capitalist agriculture in Europe and the Middle East, and general anthropological theory. Hunting, mountain climbing, and collecting old books are among his diversions.

A report on the great American forest.

# Look what happens when Mother Nature gets a little help.



These log slices dramatically show the value of modern, scientific forest management. Both (shown 36% of actual size) are from trees of about the same age. The smaller one grew in an unmanaged, overcrowded stand where it had to compete for sunlight and moisture. The other is from a grove that was thinned to give the best trees room to thrive.

This is just one of many ways forest management can help meet a predicted doubling of domestic demand for wood and paper products in the next 50 years.

The forest industry has learned how to help Mother Nature grow more trees, faster, by applying scientific forest management techniques: encouraging natural regrowth, planting superior seeds and seedlings, fertilizing, protecting against disease and insects, thinning, watching carefully until time to harvest — then starting the cycle again.

## Demand keeps rising.

Forest management like this is vital because every year Americans need more homes, more paper products, more packaging and containers, more fuelwood, more of the thousands of other essential products that only the forest can provide.

So far, the country's commercial forest has been able to keep up with demand. (*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland—whether owned by individuals, government or the industry—that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.)

But trees aren't grown equally fast by all commercial forest owners. Though industry has made striking advances on its lands, productivity is lower on privately owned lands and seriously lagging in National Forests.

## Productivity not up to potential.

Overall, the U.S. Forest Service estimates average productivity of all commercial forestland is only 61 percent of potential. And at the same time, actual acreage in commercial forests keeps shrinking, as land is withdrawn for homes, highways and other needs of an expanding population.

So we as a nation still have a long way to go if our wood and paper products are not to become scarce and expensive.

If you'd like to be better informed on how important it is to keep America's forests productive, write American Forest Institute, P.O. Box 873, Springfield, VA 22150 for a free booklet, "The Great American Forest."

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

# You and the Ecology Movement

**Prepared by**
**Luther P. Gerlach**
**Virginia Hine**
**Betty Radcliffe**

In June-July 1970 *Natural History* ran a questionnaire on the ecology movement, as it was then called; in December 1970, we reported to our readers on their responses.

Ten years later, with what is now called environmentalism a good decade old, we are running another questionnaire, based closely on the first, that we hope will tell us how the opinions and actions of our readers have changed. Perhaps it will even give us some clues as to how the ecology/environmental movement itself has changed in ten years.

Luther P. Gerlach, the anthropologist who was principally responsible for the first questionnaire, has revised his earlier work for this second look. And just as with the first questionnaire, we'll report back to you in a later issue on the response to this one. Ten years ago you told us what you thought. We'd like to know what you think now.

To answer the questionnaire, follow the instructions for each section. Mail your answers to:

Natural History,
77 West 77th Street,
New York, New York 10024

Please answer the first thirteen questions by putting in the answer box on the following page the number that best describes your attitude:

(1) Strongly agree
(2) Agree
(3) Uncertain
(4) Disagree
(5) Strongly disagree

1. I believe plants and animals exist primarily for people's use and enjoyment.
2. With advances in technology, I think people will always be able to draw the resources they need from the environment.
3. I think environmental degradation, social injustice, and economic inequality are part of the same basic problem in our society.
4. I am concerned that using nuclear sources for energy may seriously endanger human life on this planet.
5. I believe churches should be actively involved in the critical social and environmental issues of our day.
6. I think owners of private property should be free to use the plants and other natural resources on it pretty much as is now permitted by law and convention.
7. I believe the profit motive in our society (desire for individual economic gain) is outdated and must change.
8. I feel that our environmental problems probably cannot be solved by existing American political and economic institutions.
9. I think all American families, regardless of social or economic position, must limit the number of children to two or, at most, three.
10. I believe our ecological problems can be solved primarily by the application of technology.
11. I think that we are indeed running out of fossil-based fuels.
12. I believe that economic growth is nearly always good for any community.
13. I believe that I have personal responsibility in the fight against pollution.

Please answer questions 14 through 25 by putting in the answer box the number of the statement that best describes your opinion.

14. How do you see yourself in relation to the influential and powerful groups in your community?
   (1) I am part of them and have a voice in decision making.
   (2) I feel part of them although I do not make decisions.
   (3) I am part of them but dislike it.
   (4) I am outside of them, but have a voice in decision making.
   (5) I am outside of them but not opposed to them.
   (6) I am outside of them and dislike them.
   (7) I am outside of them and actively oppose them.

15. At what level can we best solve our major air-, water-, and land-pollution and degradation problems?
   (1) Increasingly manage these problems as parts of complex systems on state, federal, and international levels.
   (2) Increasingly rely on local governments to implement and enforce strong measures.
   (3) Increasingly rely on individuals to do the right thing.

16. What do you consider to be our main energy problem?
   (1) Lack of a coherent, effective national energy policy.
   (2) Shortage and/or high prices.
   (3) Social impacts of current development strategies.
   (4) Dependence upon external, especially OPEC, oil.
   (5) Decision-making process too centralized.
   (6) Ecological costs (impacts) of energy development.

17. Which of the following seems to you the most desirable approach to achievement of a better, more adaptive energy and environmental future?
   (1) Interconnecting our energy grids more tightly, for example with Canada and Mexico, in hemispheric energy systems.
   (2) Making a massive shift to fossil-based synthetic fuels, solar electric power from solar-power towers, photovoltaic arrays, or satellites.
   (3) Integrating conventional fossil-fuel technologies and renewable-energy alternatives in both centralized and decentralized, large and small systems.
   (4) Developing community level conservation methods and local energy resources.
   (5) Increasing individual self-reliance through the use of rooftop solar collectors, using wood for home heating, etc.

18. Which of the following methods do you feel will *most effectively* resolve current conflicts over energy development?
   (1) Shifting to small-scale energy technologies and decentralizing decision making about energy production and distribution.
   (2) Improving and expanding citizen participation in decision making about nuclear- and fossil-fuel development.
   (3) Improving communication to the public of scientific concepts and technological facts about nuclear and fossil-based fuels.
   (4) Seeking compromise through mediation or conciliation.

(5) Lowering our expectations to reduce consumption and to accept some environmental risk.

19. Which of the following do you consider to be our most critical environmental problem?
(1) Water pollution.
(2) Air pollution.
(3) Nuclear and other hazardous waste buildup and storage.
(4) Increased societal costs of pollution control.
(5) Inadequate or unenforced regulatory legislation.
(6) Loss of land to highways, development, urbanization, etc.

20. Please give your age group.
(1) 19 or younger
(2) 20–24
(3) 25–29
(4) 30–39
(5) 40–49
(6) 50–59
(7) 60–69
(8) 70 and older

21. What is your sex?
(1) Female
(2) Male

22. How many children do you have?
(1) None
(2) One
(3) Two
(4) Three
(5) Four or more

23. What is your level of education?
(1) Less than high school graduate.
(2) High school or equivalency diploma.
(3) Business or technical school.
(4) Some college.
(5) Two-year college degree.
(6) Four-year college degree or about to graduate.
(7) Some graduate professional school.
(8) Graduate (M.A., M.S., Ph.D.) or professional (J.D. or M.D.) degree.

24. What is your annual family income from all sources before taxes?
(1) Less than $5,000
(2) $5,000 to $7,499
(3) $7,500 to $9,999
(4) $10,000 to $14,999
(5) $15,000 to $19,999
(6) $20,000 to $24,999
(7) $25,000 to $34,999
(8) $35,000 to $49,999
(9) $50,000 to $99,999
(10) $100,000 and over

25. What is the nature of your present work?
(1) Manufacturing or distribution of products
(2) Construction, building trades, or real estate
(3) Retail, merchandising, or sales
(4) Engineering or technical
(5) Government
(6) Health services and sciences
(7) Education
(8) Social service
(9) Law
(10) Military
(11) Farming, fisheries, lumbering, mining
(12) Banking or finance
(13) Energy production or distribution
(14) Transportation
(15) Communications, arts, or entertainment
(16) Other (see answer box)

26. Please enter your Zip code.

The next six items (27–32) describe types of present, past, or ongoing activist movements. Think about how you feel about each type and place in the answer box the number that best describes the opinion you now hold of them:
(1) I support them and am active in them.
(2) I favor them generally but have not been active.
(3) I do not have a position or am uncertain how I feel.
(4) I agree with the goals but disapprove of some of the methods.
(5) I disapprove of these movements but am against repressive action against them.
(6) I disapprove and would like to see these movements suppressed.

27. Organizations or activist groups in the environmental movement.

44. Organization and your role: ______________________________

______________________________

______________________________

I completed the 1970 questionnaire: ________ yes ________ no

28. Movements for equity and social justice (for example, movements of women, blacks, and American Indians; American agriculture movement; activism of seniors, handicapped, etc.)

29. Movements, including the antinuclear movement, protesting large-scale, centralized energy development: large coal-fired power plants, high-voltage transmission lines, related coal strip mining, and deep-water oil ports and pipelines.

30. Movements promoting small-scale, renewable, chiefly solar alternative-energy technologies.

31. Movements or campaigns to make corporations more accountable for actions believed to place at risk the health and welfare of workers and consumers here and in other countries.

32. The various movements focusing on change or self-actualization of the individual either through personal experience, such as meditation, or through interpersonal experiences, such as self-help or sensitivity groups.

Answer the following questions by placing the number(s) of your response(s) in the answer box(es) as directed.

33. Do you think that there is any connection between all or many of the various movements described above? (Choose one.)

(1) They are all aspects of one single wave of revolutionary change.
(2) They may be related but are still separate movements.
(3) There is some connection between some of them.
(4) I am uncertain what I think.
(5) There is no connection between them.

34. Please enter the numbers of any of the following actions that you have personally taken primarily because of your love of, or concern for, the environment (including concern about depleting, or the environmental effects of using, our fossil energy resources).

(1) Curtailed or greatly limited use of disposables.
(2) Made a practice of separating and recycling household garbage.
(3) Modified home to conserve energy or to use renewable energy.
(4) Moved to a more energy-efficient or solar home, to higher density housing, or closer to work.
(5) Gave up or decided to forego purchase of such items as home air conditioner or recreation vehicle.
(6) Have car pooled or used public transport as much as possible.
(7) Bought smaller and/or more gas efficient automobiles.
(8) Centered more recreational activities on hiking, biking, and the like, and less on the use of motors.
(9) Canoed or backpacked in wilderness areas.
(10) Have been seeking self-sufficient living in the country.
(11) Other and/or comment (See answer box).

35. Write in the spaces provided the numbers of any of these methods of influencing decision makers that you approve of.

(1) Writing letters to government officials.
(2) Speaking at public hearings.
(3) Bringing suit against corporations, government agencies, or individuals guilty of environmental negligence.
(4) Boycotting companies that don't seem environmentally or socially responsible.
(5) Rallies, marches, demonstrations.
(6) Nonviolent direct action, such as sitting in front of bulldozers.
(7) Citizen takeovers of offices of government agencies or industries to enforce demands.
(8) Destructive or violent action if other means fail.

If you are active in the ecology movement or in activist groups or movements that you feel have a strong environmental-concern focus, please complete the questionnaire, placing in the boxes for each question the numbers of as many responses as apply.

36. Which of the methods of influencing decision makers listed in the responses for item 35 have you engaged in?

37. In which of the following ways have you personally sought to influence people to become active in the environmental movement or to interest them in environmental problems?

(1) Personally calling or speaking to individuals.
(2) Giving or helping sponsor talks or programs, live or on radio or television.
(3) Writing or helping to prepare articles, letters to editors, handout materials, or flyers.

38. If your participation in the mov
ment has involved any risks, write i
the spaces provided the numbers
any of the following you have exp
rienced.

(1) Expenditure of great time
money.
(2) Loss of friends.
(3) Threatening mail or phon
calls.
(4) Pressure from employer.
(5) Serious family rift.
(6) Loss of job.
(7) Destruction of personal pro
erty.
(8) Arrest or conviction.
(9) Bodily harm.

Now, for the final questions, ent
in the answer box the number of th
one best response.

39. How many organizations co
cerned with environmental problem
do you belong to?

(1) None (4) Three
(2) One (5) Four or more
(3) Two

40. How often do you usually tal
to other people involved in these o
ganizations (telephone conversation
formal meetings, organizational mee
ings, etc.)?

(1) Never
(2) Few times a year
(3) Once a month
(4) Once a week
(5) Twice a week
(6) Three or four times a week
(7) Daily

41. Of the five people you feel close
to, how many are also involved in the
organizations?

(1) All five (4) Two
(2) Four (5) One
(3) Three (6) None

42. Has your involvement with thes
organizations changed your idea
about yourself and made you act di
ferently?

(1) No
(2) Yes, I have changed in som
ways.
(3) Yes, I have been radicall
changed.
(4) Undecided

43. How would you rate the approac
of the group in which you are mo
active?

(1) Conservative (3) Activist
(2) Moderate (4) Radical

44. Please list the organizations activ
in environmental problems that yo
support or are active in and indicat
the type of position you have hel
in them.

# ART, REAL ESTATE, GOLD. AND VOLVOS?

There are still a few investments left today that are worth making. And these three people know them when they see them. That's why they all own Volvos.

They not only consider Volvo a safe car to be in; they also consider it a safe place to put their money. Maybe that's because over the last two years the dollar invested in a Volvo has held its value better than the dollar in your pocket.*

Of course if you're shrewd enough to invest in a Volvo, it's unlikely you'll want to turn it over quickly. Because a Volvo is made to last a long time. (The life expectancy of a Volvo is now up to 17.9 years in Sweden.)

And with the money you might save by not buying a new car every few years, you can make another investment as worthwhile as your Volvo. Like art, real estate or gold.

**VOLVO**
A car you can believe in.

## Building on Shifting Sands

From Maine to Texas, islands close to the mainland provide a coastal environment rich in estuaries, marshlands, and vacation homes. In June 1970, in "Barrier Beaches of Eastern America," Christopher Schuberth wrote about the natural processes that build up, change, and shape barrier islands such as Miami Beach, Fire Island, and Atlantic City. Waves pound the beach, storms toss the sand around, and the littoral current of water along an island shore slowly moves, if not mountains, at least beaches. On Fire Island, near New York City, the littoral current moves 600,000 cubic yards of sand westward each year.

As Schuberth pointed out, building on a barrier island is risky. The natural rearrangement due to currents and storms may not be kind to real estate or human life. Nor does development on the beaches secure them. If anything, building on barrier islands just makes things worse, particularly when residents try to halt the shifting sands.

There are federal programs to protect barrier islands, but development has been proceeding apace in recent years, and one reason, it turns out, is that the federal government, largely inadvertently, has encouraged that development. It sounds contradictory, but through unconnected programs not specifically related to barrier islands, "over three fiscal years, the permitting, granting, and licensing agencies committed nearly one-half billion dollars to barrier island development projects."

That quotation is from a Draft Environmental Statement prepared by the Heritage Conservation and Recreation Service in concert with several other federal agencies. The largest chunk of these funds came, ironically, from the Environmental Protection Agency in the form of waste-water treatment. The Army Corps of Engineers invested heavily in beach restoration and protection, which indirectly supported development. Home and business mortgage insurance programs supported investments.

It may turn out that not only the environment will suffer. The recent growth of the barrier islands' populations has occurred during a long period when storm activity has been unusually low. "Nearly 80 percent of the people now living in island cities and communities have never experienced a hurricane," according to the report. And on many islands the means of escape from storms is not adequate. "Even if they heed and take seriously a hurricane warning," says the report of the island residents, "it is doubtful that more than a relatively minor percentage could escape before the storm hits."

## Albinisms

As Carl Witkop reported in "Albinism," October 1975, abnormal pigmentation, in one form or another, affects all animals—and there are many forms. In mice, at least 147 genes at 62 loci are involved in controlling coat color.

In humans there are now thirteen known forms of albinism (and a variety of other pigment disorders that come under the name of albinoidism). Witkop has had a hand in discovering two of these thirteen since his *Natural History* article.

One form is called Autosomal Recessively Inherited Ocular Albinism, and its recognition is important in genetic counseling. A more recent discovery called simply Brown Albinism was made by a research group in Nigeria, where many albinos suffer terribly from skin cancer because they lack the protection that pigment affords from the sun's rays. Witkop and his colleagues found the new form of albinism in the members of the Ibo tribe they were studying. These albinos had a light brown skin and did not suffer increased rates of skin cancer.

## Getting Along with Seals

When Gerald Kooyman wrote h 1976 article, "Deep Divers of the An arctic," he was spending a lot of h time with seals. He and his coworke would find the 1,000-pound Wedde seals on the ice, attach recorders them, and haul them by sled to hut over an isolated hole in the ic which usually tempted the seals dive immediately. "Occasionally wrote Kooyman, "a seal did not ent the water for several hours and the we were obliged to share our hut wi the animals for the evening or tl night—which reminded us of the jol about where does a 500-pound goril sleep."

Kooyman is still spending time wi seals, but he has his hut to himse now. He has turned to more ecolog cally, less physiologically oriente studies of how free-ranging seals div As expected, seals dive for shorter p riods of time when they are free ran ing. In a forced dive, they spend longer time under the ice because the are looking for a new hole to surfac through, not wanting to return to th "laboratory." Kooyman has yet to an lyze his data to produce any clea conclusions, but he did say the dept and length of the dives were high variable.

Although he has solved the hu problem, his work is still not the sam as dealing with white mice. Researc ers must approach a seal, put a ba over its head, and attach a record to its skin with what are known a hog rings, which pierce the skin. Koo man says the seals have tough an insensitive skin, and attaching the r corders causes little pain. But the sea tend not to like the whole process ve much. Which brings up the questic of how do you handle an unhapp 1,000-pound seal. Very carefully?

*James Gorma*

# Nutritional Ambiguities

*A diet suitable for one individual may be dangerously deficient for another*

**by René Dubos**

Many people of the Western world, especially in the United States, are intensely worried about their nutritional state and the quality of their food. This worry, however, is not caused by malnutrition but by constantly reading and hearing about the dangers of bad diets and of food contaminated with additives and other chemicals. Any departure from what Westerners assume to be an ideal natural diet is publicized by the mass media, thus contributing to the prevalent social neuroses about the general state of the world.

The reality is that most people in the developed and even semideveloped parts of the world now have diets that are better balanced and freer of toxic contaminants than at almost any time in the past, except perhaps during the Old Stone Age. Food shortages occurred frequently, even in Europe, as recently as a century ago, vitamin and other deficiencies affected many people at the end of the winter, microbial spoilage of food was difficult to avoid, and contamination with toxic substances often caused acute disease and death. It took Upton Sinclair's hair-raising stories in *The Jungle*, published in 1906, to make Congress create the Food and Drug Administration, which, among other functions, oversees the safety and quality of foodstuffs.

I do not claim that our food and our nutritional state are now ideal, but I believe that their most serious shortcomings do not stem from a deterioration of our dietary regimen. If some, and perhaps many, of us are in a state of *mal*nutrition, it is because our dietary regimen is ill-adapted to modern conditions. It would be surprising if the nutritional regimens designed for the old ways of life were the right ones for the conditions prevailing in today's wheel-borne, well-heated, air-conditioned societies. We know a great deal about the characteristics of the various kinds of food but very little about what would be the ideal food intake for a particular person in a particular physiological, behavioral, or occupational situation.

Until recent times, nutritional science has dealt chiefly with such general problems as the chemical identification and synthesis of essential growth factors; the determination of the average requirements for each one of these factors, according to age, sex, and state of health; the metabolic role and fate of each one of the foodstuffs in the body. Under normal conditions, this broad theoretical approach was based on the belief that, within a given age group and sex, all human beings have essentially the same nutritional requirements. Initially, for example, the requirements for young male adults were determined by tests on healthy, vigorous American students at an Ivy League college. But many recent studies have revealed that every person has a nutritional-metabolic pattern that is characteristic, indeed as unique as fingerprints. For this reason, a diet that is suitable for one person may be marginal, deficient, and even dangerous for another.

Individual differences in nutritional requirements can be considerable. A recent study of nineteen healthy men found an almost fivefold difference in their daily requirements for calciu (from 220 to 1,018 mg) and two- seven-fold differences in their nee for the various essential amino aci that maintain nitrogen balance. The differences are certainly due in pa to genetic constitution, but exper ments in animals and observations i human beings leave no doubt that th nutritional needs of an individual ca undergo profound changes as a resu of adaptation to a shortage or abu dance of certain nutrients.

Some twenty years ago, a study wa made in India of a large group o beggars who had long been on a die deficient in calories, iron, calcium phosphorus, vitamins A, B, C, an D, and proteins of animal origin. T their great surprise, the investigator found that only 4 percent of thes beggars showed obvious signs of nutritional deficiency and that radiological examinations showed most o them to have a normally calcified ske eton. In the women of this group, lo nutritional intakes did not have markedly deleterious effect on eithe pregnancy or lactation; the growt rate of children was only slightly lowe than normal. While these beggar probably used items of food that escaped the attention of the investigators, nevertheless chronic food shor age appears to have created in ther some form of physiological adaptatio to low nutritional intake.

The ability to survive and even t function well with an inadequate die can probably be attributed in part t people in underprivileged countrie learning to eat certain items—incluc ing insects—considered unacceptabl in richer countries. Above and beyon

# FORD'S EXCLUSIVE CLUB ROOM

**1980 Ford Captain's Club Wagon. Best EPA gas mileage rating of any van. Station wagon luxury—much more room.**

Here's one exclusive Club everyone can easily enter! Ford's advanced Club design means more move-around room for driver and plenty of inside passenger comfort. Built tough: Separate body-on-frame construction, rugged Twin-I-Beam suspension. See your Ford Dealer. And ask about Ford's Extended Service Plan.

**BEST VAN GAS MILEAGE**

**18** EPA EST.* **26** Hwy. EST.*

Built Ford Tough

*300 Six, optional 4-spd. manual transmission. Compare these estimates with others. Your mileage may differ, depending on speed, distance and weather. Actual highway mileage will probably be less than estimated. California estimates lower.

**Welcome inside the Club.** Ford's Captain's Club Wagon comes with fold-out snack/game table, four recline/swivel chairs, and seat/bed.

**Combination seat/bed.** Folding rear seat turns Ford's Captain's Club Wagon into a mini camper.

**Super wagon size, too!** Ford wagons offer seating plans for four to 15 passengers. And Ford Club Wagons offer light- and heavy-duty Trailer Towing Package options.

FORD

FORD DIVISION Ford

these "social" adaptations, however, undernourished or malnourished people can also develop certain "biological" adaptations that supplement the food intake, such as the synthesis of vitamins and amino acids by intestinal microbes. Perhaps of greater importance are "metabolic" adaptations that enable the body to "gear down" its metabolic demands.

The existence of multiple forms of nutritional adaptation certainly accounts for the fact that persons differ widely in their nutritional requirements, the result not only of genetic differences but also, and even more, of different cultural habits, ways of life, and behavioral patterns. These differences make a mockery of attempts to define precisely an optimum diet for the hypothetical average person.

Many people believe that they can function well only when provided with three square meals a day, and certain students of nutrition believe that this formula constitutes the surest way to a good nutritional state. But, in fact, few are the societies in which the practice of three square meals a day is considered essential for health.

In the economically humble French environment from which I emerged, the substantial meal was eaten at noon, supper was a desultory affair, and as to breakfast, it consisted of bread with a cup of cocoa for children and coffee for adults. Never did a glass of orange juice or tomato juice reach my lips until I had settled in the United States. Yet here I am to tell the tale at the age of seventy-nine. My sister and brother, who are both in their late seventies and living in Paris, are still doing well on the same regimen, as are my French nephews and nieces. There are tribes in which people nibble constantly and others whose members partake of only one meal a day. At Harvard University, I knew a famous medical educator who ate only at dinnertime, when he could make the meal an elaborate social occasion.

In East Africa, the Kikuyu people are healthy and can develop a good physique on a vegetarian diet. In contrast, the Masai people, who live in the same region, derive practically all their nourishment from milk and from the blood of their cattle, which they bleed daily. Yet the Masai do as well as the Kikuyu without much intake of the plant fiber that is so much on our minds today.

I could go on and on with examples illustrating that social groups and individual persons have successfully adapted themselves to very different dietary regimens. I find it more useful, however, to discuss at some length a more drastic phenomenon of nutritional adaptation, namely, adaptation to extremely low food intake throughout the life span.

During the 1940s, I participated in the research activities of the Institute of Nutrition for Central America and Panama, situated in Guatemala City. The average per capita food intake in the villages of Guatemala was then, and still is, extremely low and deficient in protein. Many children and young adults died of infection. But those who survived to adulthood, although of short stature and seemingly frail, were capable of far greater physical efforts than those expected of vigorous Europeans and North Americans—such as carrying heavy burdens on their backs over long distances up and down mountains. Physiological studies showed that they could maintain themselves in caloric and nitrogen balance on a diet that would have meant starvation for most Europeans and especially for North Americans. Furthermore, these skinny people, grossly undernourished according to our standards, commonly lived to a good old age.

Since Guatemalans raised in wealthier surroundings and fed a rich and abundant diet became as large as people of Europe and North America and exhibited the high nutritional requirements of these countries, we can assume that the anatomical and physiological characteristics of the adult village Guatemalans were not the consequence of genetic peculiarities but rather of adaptation to low food intake.

Before World War II, most adult Japanese men and women were of small size, and this is still true of Japanese persons more than forty years old. In contrast, the average size of Japanese teen-agers and young adults is now close to that of young Caucasians in the prosperous parts of the world. The phenomenal increase of body size in Japan cannot be due to genetic factors since it occurred within one generation. One reason may be the control of childhood disease; another is certainly the profound changes in the Japanese diet since the end of the war. Between 1950 and 1975, for example, the per capita average consumption increased *15-fold* (not 15 percent) in the case of milk, 7.5-fold in the case of meat and eggs, and 6-fold in the case of fat, while the per capita consumption of rice and potatoes decreased significantly.

Thus it seems certain that the prewar Japanese people had adapted biologically to a low intake of certain nutritional elements (probably protein and fat) by remaining small throughout life. This biologically adaptive state had such profound effects that adult and old Japanese people who grew up under such conditions do not significantly increase in size even when they adopt today's much richer and more abundant diet.

As already mentioned, by the beginning of the century American nutritionists had worked out Recommended Daily Allowances for the various essential nutrients, in particular, proteins; these values were derived from the requirements of vigorous young adults, chiefly college students. Almost unanimously, however, nutritionists of other countries have long considered the American Recommended Daily Allowances far too high. In the early 1970s, the commissions on nutrition of the World Health Organization and of the Food and Agricultural Organization scaled down the protein requirements of a healthy person by some 30 percent—thereby eliminating, by administrative decision, the international "protein gap" that had been postulated in earlier decades.

Recent American research has been interpreted to mean that the redefined protein standards are in reality too low because in one study a group of U.S. university students developed signs of deficiency two months after being fed the new recommended levels of protein. The explanation of this finding, however, is probably that some twenty years ago most American children were fed (and to a large extent most still are) diets much richer and more abundant than those given European children, let alone children of underdeveloped countries. The nutritional requirements of adults are probably largely determined by nutritional conditioning during the early years of life.

Average Americans, and now many Europeans, feel that they need a daily food intake containing more than 2,500 calories and 70 grams of protein, preferably meat protein. In contrast, whole populations of other ethnic groups seem well adapted to diets pro-

if you will join now for a trial period and agree to take 3 more books—at handsome discounts—over the next 12 months.

Here's a fantastic opportunity to acquire a specially selected set of four outstanding books on birding—all for $2.95. These four volumes have a publishers' list price of $50.80. Together they form a marvelously useful Basic Birding Library. You'll find them heaping with more than 2,000 pages on everything you need to know about birds and birding—from mating, nesting, and migration to the best places to bird in your state to how to easily identify over a thousand bird species.

Take a look at the four books you'll get:

**An Introduction to Ornithology.** *Wallace and Mahan. The* uncontested basic book on birds, this amply illustrated volume offers 550 fact-filled pages on bird behavior, courtship, anatomy, orders and families, flight, and much more. Publisher's price: $15.95

**The Audubon Society Field Guide to North American Birds: Volume I: Eastern Region; Volume II: Western Region.** These two volumes *each* offer 700 information packed pages. *Each* offers more than 550 color photographs on living birds in their natural habitats. Each is ingeniously organized for quick identification. Publisher's price for each volume: $9.95

**Guide to the National Wildlife Refuges.** *Riley and Riley.* The *only* complete guide to all of America's almost 400 wildlife refuges. Tells how to get there and when to go, where to stay and what to do, what birds to expect and where to find them, and much more. Publisher's price: $14.95

**What is the Birding Book Society?** A small, highly-specialized book club. A club created exclusively for all who take pleasure in the world of birds—from the backyard birdwatcher to the birding expert. The Birding Book Society offers big, bright fact-filled books on every aspect of birds and birding. Field guides...basic references... personal observations...photographic appreciations...new works and classics—you name it and we've got it. Add to that handsome savings on the selections you buy (up to 30% off the publisher's price and sometimes even more)...plus a Bonus Book Plan that lets you save at least 70% off the publisher's price. Join today and start taking advantage of the many benefits of the Birding Book Society.

If reply card has been removed, please write to: **Birding Book Society**, Dept. N-AB5, Riverside, N.J. 08370 to obtain membership information and an application.

viding approximately 1,500 calories and 40 grams of protein, or even less, and often with hardly any meat. This was the case in Japan before the war and is still the case for most Guatemalan villagers. Moreover, the immense majority of people in all ethnic groups could almost certainly adapt successfully to either one of these two extreme types of dietary regimen or to any in between. We need to learn much more about the effects of nutritional conditioning, especially during early childhood, because several of these effects might be essentially irreversible and could therefore affect the person during the whole life span.

The most obvious long-range effects have to do with health. Good evidence exists, for example, that babies pressed to take more food become habituated to an abundant diet and tend to become obese, with all the health risks associated with obesity during adulthood and old age. The postwar generation of richly fed Japanese, both men and women, now tend to have the same disease patterns that are prevalent in North America and Europe, where cardiovascular diseases and various forms of cancer have become the leading causes of death. In all prosperous societies, people are becoming increasingly concerned about the harmful components of their diets—cholesterol, saturated fatty acids, processed foods, contaminants such as pesticides, and various forms of additives. They would worry even more if they realized that almost any article of food—even the most natural food—is toxic if taken in excess. For example, potatoes contain solanin, a substance that would create toxic effects if ten times the usual amount were eaten at one sitting; cereal grains contain phytic acid, which interferes with the absorption of calcium and iron; and certain plants of the cabbage family produce goiter. Even vitamins can be a cause of disease as in the case of hypervitaminoses A and D.

While proving that many particular food items, artificial or natural, are dangerous if taken in large amounts is fairly easy, establishing the dangers of the typical rich American diet is much more difficult. A very recent study sponsored by the American Society for Clinical Nutrition examined a number of suspected relationships between diet and disease but found only three that could be statistically confirmed: between sucrose and dental caries; between alcohol and cirrhosis of the liver; between salt and hypertension. Convincing evidence could not be obtained that high intakes of cholesterol and fatty acids increased the chance of dying from cardiovascular disease.

Lack of statistical proof does not, of course, rule out that high blood levels of cholesterol and fatty acids can be involved in disease causation. The great differences of response among the persons examined make it difficult to establish statistically valid correlations. As mentioned earlier, these differences may have their origin not only in genetic constitution but also in behavioral patterns. One example will suffice to illustrate how a seemingly trivial aspect of behavior can influence the digestion of lipids and, consequently, their possible effects on disease. After a meal, ingested lipids travel in the bloodstream for a short time in the form of microscopic particles called chylomicra. These particles are rapidly digested under normal conditions, but they persist much longer in a person under stress even when the stress is as mild as having to give an anatomy lecture to medical students. If lipids do contribute to the formation of vascular lesions, adaptation to certain stresses may thus decrease their ability to cause cardiovascular disease.

Nutritional science therefore involves much more than knowing the requirements for essential growth factors and the toxic effects of food additives. A time may come when a particular patient's need for a particular food will be evaluated not only by measuring growth rates but also by determining the food's effect on specialized functions, such as the ability to develop scar tissue; produce new cells in the liver, spleen, and bone marrow; and generate the proper kind of response to detoxify poisons or drugs. There is now some evidence that the nutritional state can affect even behavioral responses, as shown by the brain's production of at least two neurotransmitters: serotonin which depends on the tryptophane level in the bloodstream, and acetylcholine, which depends on the choline level. Neither tryptophane nor choline can be manufactured by the body and must be supplied in the diet.

We have an immense amount of detailed knowledge about foodstuffs but know very little about their effects on the body and even less about their effects on behavior and on the social aspects of life. Developing a large body size is obviously an advantage for certain activities but probably not for others. Voltaire was a midget compared with Washington but outlived him by seventeen years and was at least as influential on the course of history. The small prewar Japanese could not play basketball with Americans; nevertheless, they were excellent soldiers and proved immensely successful in the technological and economic world of the postwar period. The new generation of richly fed Japanese is much taller than the preceding one but we do not know that its members will live longer or be happier. A good, abundant nutritional regimen will keep us alive, make us grow to a certain size, and protect us from deficiency diseases, but beyond that, we really do not know much about its effects on our bodies, our society and the future of civilization.

To illustrate our ignorance, and also the possibility of adapting successfully to extremely different dietary regimens, I shall mention the nutritional habits of two famous physicians whom I knew well during my early years at the Rockefeller Institute for Medical Research. One was Henry William

Welch, the architect of medical and public health sciences in the United States. The other was Oswald T. Avery, who is famous for his studies on infectious diseases and for having first demonstrated that DNA is the carrier of hereditary characteristics. Welch and Avery were approximately the same height, had received similar college and medical educations, spent most of their lives in academic medicine, remained bachelors, smoked a great deal, took practically no physical exercise, and never tired of talking. But they differed competely in nutritional behavior.

Welch had a Gargantuan appetite, with a preference for rich, well-seasoned foods. He was inordinately fond of sweets and prone to end his meal with several helpings of ice cream—in a period when this meant real cream. He loved wine and hard liquor and seemed proud that his most violent form of exercise was taking off his shoes at night and putting them on in the morning. He early became obese, loved fun and the carnival aspects of life, and remained intellectually active to the end of his life. He died of cancer in his eighty-fifth year.

Avery ate sparingly. Two slices of toast, a few leaves of lettuce, and several cups of coffee seemed to be his ideal meal. We used to say that he could be in nutritional balance only by fixing atmospheric nitrogen. He never weighed more than ninety pounds during the thirty years I knew him, yet he was constantly active, either in laboratory work or participating in discussions. He suffered from mild hyperthyroidism, and his disease took a more active form during a period of disappointments in his research program. After surgery and a few months rest, he came back to the laboratory and resumed his activities. He died of cancer in his seventy-ninth year.

As far as I know, no nutritional studies have been carried out on either Welch or Avery. One can take it for granted that genetic differences between them played a role in their contrasting attitudes toward food intake and responses to it, but one can also assume that their nutritional habits and their metabolism were profoundly influenced by other aspects of their ways of life, and probably by their early experiences. It takes more than a knowledge of foodstuffs to create a science of human nutrition. □

AVAILABLE NOW
CHARLES DARWIN
THE ZOOLOGY OF
THE VOYAGE OF H.M.S. BEAGLE

A Three Volume,
Limited Edition, Facsimile Reprint

Described here are the many unique animals Darwin encountered on his epic voyage. Among the superb illustrations are 50 colour plates of birds by the renowned John Gould.

Sumptuously produced in 3 Volumes, 1,096 pages, numerous colour plates and B/W illustrations, bound in genuine leather and linen. To the discerning collector these books offer outstanding investment value.

**Here's your opportunity to receive a choice collection of the latest annual reports from leading corporations. Use the handy coupon. There's no obligation.**

The Dun & Bradstreet Corporation
1979 Annual Report

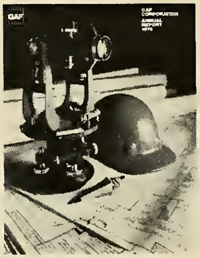
## THE DUN & BRADSTREET CORPORATION

The Dun & Bradstreet Corporation provides products and services in four groups: business information, publishing, marketing services and broadcasting. The company is the largest producer and disseminator of business information in the private sector. Earnings per share in 1979 were a record $3.19, up 26.6%, and more than double those of four years ago. Dividends were increased for the 28th consecutive year.

ÆTNA LIFE & CASUALTY

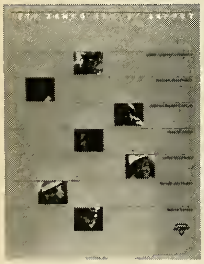
## ÆTNA LIFE & CASUALTY

Ætna Life & Casualty—largest investor-owned insurance organization in U.S., also in business financing, real estate development, technology enterprises. 1979 earnings reached new high of $560 million or $6.93 per common share, 21% return on shareholders' equity. Revenues rose 21% to $11.4 billion. Assets, shareholders' equity grew to $30.2 billion and $35.56 per common share. Annual dividend per common share increased 18% to $2.12 with May 15 payment. Annual dividend 194% greater than five years ago.



## GAF CORPORATION

GAF is expanding advanced technology in its chemical, building materials and reprographic businesses. Its specialty chemicals are gaining new applications in products as diverse as shampoos and auto parts, wines and adhesives. Its roofing, siding, insulation and vinyl floorings are in demand for remodeling and repair work as well as in new construction. GAF's diazo reprographic systems are moving into fields long monopolized by silver-based films and papers. 1979 sales were $1.2 billion.



## ARMCO INC.

We turned in record sales and earnings in 1979. Our annual report tells how we did it, reports results, both current and historical and describes our strategic plans for the future. We're a diversified five billion dollar corporation, organized with seven lines of business: Oilfield Equipment and Production, Fabricated Metal Products, Industrial Products and Services, Financial Services, Carbon Steel Products, Specialty Steel Products, Mining and Raw Materials.

Northern Natural Gas Company Annual Report 1979
INTERNORTH

## INTERNORTH (Northern Natural Gas)

Record earnings and revenues highlighted 1979, Northern's fiftieth year. Net income was a record $185.5 million. Operating revenues totaled a record $2.5 billion. Property, plant and equipment, at cost, now exceeds $3 billion. Earnings per share of $8.17 were our highest ever. Northern is an energy-based company involved in natural gas, liquefied fuels, petrochemicals, oil and gas exploration and coal operations.

Ashland Oil 1979
Annual Report for the New Generation
Ashland

## ASHLAND OIL

This year Ashland, the nation's largest independent refiner and marketer, published two annual reports. One for today's investors. One for the new generation of investors. This colorful report discusses facts from the 1979 Annual Report—explaining how private investors make our progress possible.

Like these record fiscal 1979 results: Revenues—$6.7 billion; net income $526 million. Dividends increased from annual rate of $1.33 in 1978 to a current annual rate of $2.20. Both annual reports will be sent.

KOPPERS
1979 Annual Report

## KOPPERS COMPANY, INC.

Investment in Koppers over the past five years produced an average total return of 29% per year to shareholders. The highly diversified industrial operations of the company are strategically situated so that 75% of sales are in the construction and capital spending segments of the economy and 25% in intermediate industrial products. This product mix gives Koppers a decided edge in providing future growth and continued high returns to investors.

# of the Year. Free.

## THE MEAD CORPORATION

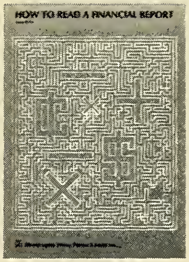
1979 another record year: 17% increase in net earnings to $141 million resulted in record 18.1% return on shareholders' equity. Fully diluted earnings per share reached $5.19 from $2.72 in '74—a compound growth rate of 14%—one of the most impressive in the forest products industry. Dividends have increased for seven consecutive years to annual rate of $1.80 per share.

## W.R. GRACE & CO.

Last year our Annual Report was judged best among 2,000 other companies. In 1979 it's even better with net income up 30% to $223 million, record sales of $5.3 billion up 18% and a market price ahead 57%. But we're no one-time champion. Over the decade of the seventies, our earnings have risen at a compound rate of more than 31% per year. Shouldn't you look into GRACE? Our 75,000 shareholders are glad they did.

## COMBUSTION ENGINEERING

The Energy Systems Company... Combustion Engineering is a diversified corporation which provides equipment, products and services for oil and gas exploration and production, petroleum and petrochemical processing, environmental control, electric power generation, synthetic fuels, and other energy-related industrial applications. C-E has annual sales approaching $3 billion, and a current annual dividend rate of $2.60, which has been increased eight times in the last five years.



## HOW TO READ A FINANCIAL REPORT

Plain talk in this 32 page booklet cuts through the financial mumbo jumbo. Explains what terms like "net fixed assets" and "total shareholders equity" mean. Shows how to use an annual report as a guide for investment decision making.

**MERRILL, LYNCH, PIERCE, FENNER & SMITH, INC.**

Great Northern Nekoosa Corporation 1979 Annual Report and 10-K

## GREAT NORTHERN NEKOOSA CORP.

Great Northern Nekoosa, a major pulp and paper company and the world's largest producer of copier paper, has large, efficient mills which produce low cost business papers, containerboard, newsprint and groundwood printing paper. GNN's assets include nearly 7,000 tons a day of pulp and paper capacity, 2,800,000 acres of timberland, millions of tons of coal reserves, and an extensive hydroelectric system. At just over 70%, GNN's energy self-sufficiency is among the highest in the paper industry.

## DOMINION BRIDGE COMPANY, LIMITED

During the Seventies this diversified international company achieved a 28% compounded annual growth rate of net income, while multiplying worldwide sales fivefold—to nearly $1 billion in 1979. During the decade its net income rose 970% and its growth rate exceeded 490 of the *Fortune* 500. Engaged principally in manufacturing steel-based products, engineering and construction activities, Dominion Bridge is traded on the Toronto and Montreal Stock Exchanges.

# Hen's Teeth and Horse's Toes

*Rather than an embarrassment, "throwbacks" are evolutionary reminiscences with intriguing implications*

**by Stephen Jay Gould**

Vanity license plates are just the latest expression of an old conviction that distinctive conveyances reflect status or, at least, compel notice. We can build our modern machines to order, but nature has narrower limits. Horses of unusual size or color commanded great favor, but Julius Caesar ventured beyond the mere accentuation of normality in choosing his favorite mount. The historian Suetonius writes that Caesar

> used to ride a remarkable horse, which had feet that were almost human, the hoofs being cleft like toes. It was born in his own stables, and as the soothsayers declared that it showed its owner would be lord of the world, he reared it with great care, and was the first to mount it; it would allow no other rider.

Normal horses represent the limit of evolutionary trends for the reduction of toes. Ancestral *Hyracotherium* (popularly, but incorrectly, known as *Eohippus*) had four toes in front and three in back, while some earlier forebear undoubtedly possessed the original mammalian complement of five on each foot. Modern horses retain but a single toe, the third of an original five. They also develop vestiges of the old second and fourth toes as short splints of bone, mounted high and inconspicuously above the hoof.

Abnormal horses with extra digits have been admired and studied since Caesar's time. O.C. Marsh, a founder of vertebrate paleontology in America, took a special interest in these aberrant animals and published a long article on "Recent polydactyle horses" in the *American Journal of Science* for April 1892. Marsh had two major claims upon fame, one dubious—his acrimonious battles with E.D. Cope in collecting and describing vertebrate fossils from the American West—and one unambiguous—his success in deciphering the evolution of horses, the first adequate demonstration of descent provided by the fossil record of vertebrates, and an important support in Darwin's early battles.

Marsh was puzzled and fascinated by these aberrant horses with extra toes. In most cases, the additional toe is merely a duplicate copy of the functional third digit. But Marsh found that a fair number of two- and three-toed horses had harkened back to their ancestors by developing either or both of the side splints into functional (or nearly functional) hoofed toes. (A later, and particularly thorough, German monograph of 1918 concluded that about two-thirds of horses with extra toes had simply duplicated the functional third digit, while about one-third had resuscitated an ancestral feature by developing the vestigial splints of their second or fourth toe into complete, hoofed digits.)

These apparent reversions to previous evolutionary states are called atavisms, after the Latin *atavus*: literally, great-great-great-grandfather; more generally, simply ancestor. The biological literature is studded with examples of the genre, but they have generally been treated anecdotally as mere curiosities bearing no important evolutionary message. If anything, they are surrounded with the odor of slight embarrassment, as if the progressive process of evolution did not care to be reminded so palpably of its previous imperfections. The synonyms of European colleagues express this feeling directly—"throwback" in England, *pas-en-arrière* ("backward step") in France, and *Rückschlag* ("setback") in Germany. When granted any general significance, atavisms have been treated as marks of constraint, as indications that an organism's past lurks just below its present surface and can hold back its future advance.

I would suggest an opposite view—that atavisms teach an important lesson about potential results of small genetic changes, and that they suggest an unconventional approach to the problem of major transitions in evolution. In the traditional view, major transitions are a summation of the small changes that adapt populations ever more finely to their local environments. Several evolutionists, myself included, have become dissatisfied with this vision of smooth extrapolation. Must one group always evolve from another through an insensibly graded series of intermediate forms? Must evolution proceed gene by gene, each tiny change producing a correspondingly small alteration of external appearance? The fossil record almost never records smooth transitions, and it is often difficult even to imagine a function for all hypothetical intermediates between ancestors and their highly modified descendants.

One promising solution to this dilemma recognizes that certain kinds of small genetic changes may have

# You've Just Come Face to Face With The Real World.

This is Eduardo. He lives with his mother, two sisters and his grandparents in Central America. Their home is a tile-roofed hut with a dirt floor, no sanitation and no running water. Eduardo suffers from malnutrition and needs medical attention, but his family can't afford a doctor.

His world is one of poverty and hunger. But you can help change that for a child like Eduardo by becoming a sponsor.

Through Christian Children's Fund, you can reach out and help give a child what he needs to live a healthier, happier life.

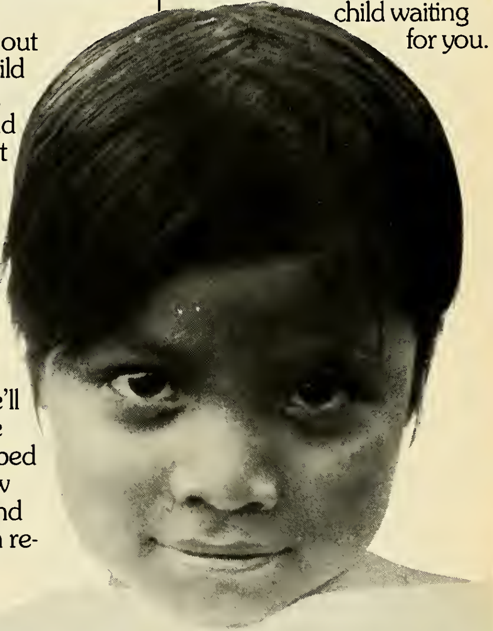
When you become a sponsor, you're helping to give some of the basic things a child needs just to get through a day—nourishing meals, clothing, proper medical attention, a chance to go to school, or whatever is needed most. Your 50¢ a day goes a long way toward helping alleviate some of the most serious problems a child has to face in his world. Without your help, he might not have much hope.

When you send your regular monthly payment of $15, 80% or more is used for the program where the child you sponsor receives assistance, and is pooled with funds from sponsors helping other children in that program. There, the money is used for the children's individual and group needs.

We're proud of our efficiency in child care services. Our combined administrative and fund-raising costs are among the lowest of any non-profit agency. A full audit, as reported by Peat, Marwick, Mitchell & Co., is included in our annual report and mailed to sponsors and contributors each fall.

Please reach out and help the child who needs you. You needn't send any money right away. Just mail in the coupon. Christian Children's Fund will send you a child's photograph and family background information. We'll tell you how the child will be helped and explain how you can write and receive letters in return. It's a special way for a child to share his world with you.

When you give $15 a month for a child, you're sending much more than money. You're sending love. Please mail in the coupon today. There's a child waiting for you.



## Send Your Love Around The World.

Dr. Verent J. Mills QNHY76
CHRISTIAN CHILDREN'S FUND, Inc., Box 26511, Richmond, VA 23261

I wish to sponsor a boy ☐ girl ☐ any child ☐ who needs my help. Please send my information package today.

☐ I want to learn more about the child assigned to me. If I accept the child, I'll send my first sponsorship payment of $15 within 10 days. Or I'll return the photograph and other material so you can ask someone else to help.

☐ I prefer to send my first payment now, and I enclose my first monthly payment of $15.

☐ I cannot sponsor a child now but would like to contribute $ ______.

major, discontinuous effects upon morphology. We can make no one-to-one translation between extent of genetic change and degree of alteration in external form. Genes are not attached to independent bits of the body, each responsible for building one small item. Genetic systems are arranged hierarchically; controllers and master switches often activate large blocks of genes. Small changes in the timing of action for these controllers often translate into major and discontinuous alterations of external form. Most dramatic are the so-called homeotic mutants causing spatial shifts in the expression of blocks of genes. In *bithorax* mutants of the fruit fly *Drosophila*, for example, small changes in any of five closely linked genes cause posterior parts of the body to appear in more forward positions or anterior parts to develop farther back. Changes are often discontinuous, not graded. Halters, organs used for maintaining balance during flight, may be replaced by true wings. In an even more striking and peculiar mutation, called *aristapedia*, the tarsus of a leg, with all its structures, appears on the head where an antenna should form.

The current challenge to traditional gradualistic accounts of evolutionary transitions will take root only if genetic systems contain extensive, hidden capacities for expressing small changes as large effects. Atavisms provide the most striking demonstration of this principle that I know. If genetic systems were beanbags of independent items, each responsible for building a single part of the body, then evolutionary change could only occur piece by piece. But genetic systems are integrated products of an organism's history, and they retain extensive, latent capacities that can often be released by small changes. Horses have never lost the genetic information for producing side toes even though their ancestors settled on a single toe several million years ago. What else might their genetic system maintain, normally unexpressed, but able to serve, if activated, as a possible focus for major and rapid evolutionary change? Atavisms reflect the enormous, latent capacity of genetic systems, not primarily the constraints and limitations imposed by an organism's past.

My columns often suffer from runaway introductions, fueled by overenthusiasm for a latent generality inspired by a particular story. The preceding paragraphs were suggested by a recent report of something that has no right to exist if one of our most venerable similes expresses literal truth—hen's teeth. In *Science* for February 29, 1980 (enough of a rarity in itself), E.J. Kollar and C. Fisher reported an ingenious technique for coaxing chickens to reveal some surprising genetic flexibility retained from a distant past.

They took epithelial (outer) tissue from the first and second gill arches of a five-day-old chick embryo and combined it with mesenchyme (inner embryonic tissue) of sixteen- to eighteen-day-old mouse embryos from the region where first molar teeth form. A fascinating evolutionary tale lies hidden in this simple statement as well. Jaws evolved from bones supporting the anterior gills of ancestral fishes. All vertebrate embryos still develop the anterior gill arches first (as ancestral embryos did) and then transform them during development into jaws (as ancestors did not in retaining the forward gills throughout life). Thus, if the embryonic tissues of chickens still retain any capacity for forming teeth, the epithelium of the anterior gill arches is the place to look.

Kollar and Fisher took the combined embryonic tissue of mouse and chicken and grew it in what might strike readers as a bizarre and unlikely place—the anterior chambers of the eyes of adult nude mice (but where else in an animal's body can one find an open space, filled with liquid that is not circulating?). In ordinary teeth, made by a single animal, the outer enamel layer forms from epithelial tissue and the underlying dentin and bone from mesenchyme. But mesenchyme cannot form dentin (although it can produce bone) unless it can interact directly with epithelium destined to form enamel. (In embryological jargon, epithelium is a necessary inducer, although only mesenchyme can form dentin.)

When Kollar and Fisher grafted mouse mesenchyme alone into the eyes of their experimental animals, no dentin developed, but only spongy bone—the normal product of mesenchyme when deprived of contact with enamel epithelium as an inducer. But among fifty-five combined grafts of mouse mesenchyme and chick epithelium, ten produced dentin. Thus, chick epithelium is still capable of inducing mesenchyme (from another species in another vertebrate class yet!) to form dentin. *Archaeopteryx*, the first bird still possessed teeth, as did severa fossils from the early history of birds But no fossil bird of the past sixt million years has produced teeth while the toothlessness of all moder birds ranks with wings and feather as defining characters of the class Nonetheless, although the system ha not been used on its home groun for perhaps a hundred million generations, chick epithelium can still induce the formation of dentin whe combined with appropriate mesenchyme (chick mesenchyme itself ha probably lost the ability to form dentin, hence the toothlessness of hen and the necessity for using mice).

Kollar and Fisher then found something even more interesting. In fou of their grafts, complete teeth had developed! Chick epithelium had no only induced mouse mesenchyme t form dentin; it had also been abl to generate the enamel matrix proteins. (Dentin must be induced by epithelium, but this epithelium canno differentiate into enamel unless it, i turn, can interact with the very denti it has induced. Since chick mesenchyme cannot form dentin, chick epithelium never gets the chance to show its persistent stuff in nature.)

One final point stunned me ever more. Kollar and Fisher write of thei best tooth: "The entire tooth structur was well formed, with root development in proper relation to the crown but the latter did not have the typica first-molar morphology, since it lacke the cusp pattern usually present i intraocular grafts of first-molar rudiments." In other words, the tooth look normal, but it does not have the form of a mouse's molar. The odd form may, of course, simply result from th peculiar interaction of two systems no meant to be joined in nature. But i it possible that we are seeing, in part the actual form of a latent bird' tooth—the potential structure tha chick epithelium has encoded for sixt million years but has not expresse in the absence of dentin to induc it?

Kollar and Fisher's work recalle another experiment from the opposit end of a chick, a famous story usuall misreported by evolutionary biologist (once, I am embarrassed to say, b myself), as I discovered in trackin down the original source. In 1959, th French embryologist Armand Hamp reported some experiments on the de

© 1979 VOLKSWAGEN OF AMERICA

# 1980 DASHER DIESEL. THE BEST MILEAGE WAGON IN AMERICA.

The VW Dasher Diesel not only gets better mileage than any other wagon in America, it gets better mileage than most other cars in America. (EPA est. $\boxed{36}$ mpg, 49 mpg highway estimate. Use est. mpg for comparisons. Mpg varies with speed, trip length, weather.

(Actual highway mileage will probably be less.)

The Dasher Diesel wagon is big enough to hold a fair-sized calf. But the inside is so handsome, you'll want to keep the livestock elsewhere.

"Quality pervades wherever one looks, and it's pleasing to the eye as well as to the touch," says Motor Trend. "It's so nice that you'll feel as if you're driving a much more expensive car."

Breezin' by all them gas stations, you'll recollect what Car and Driver said: "It has a way of going much like that of a fine horse, precise and proud."

So, pardner, if someone tells you there ain't no way to put downright luxury together with downright economy, you can give 'em a quote from us:

"Bull."

**VOLKSWAGEN DOES IT AGAIN**

velopment of leg bones in chick embryos. In ancestral reptiles, the tibia and fibula (the bones between your kneecap and ankle) are equal in length; the ankle region below includes a series of small bones. In *Archaeopteryx*, the first bird, tibia and fibula are still equal in length, but the ankle bones below have been reduced to two, one articulating with the tibia, the other with the fibula. In most modern birds, however, the fibula has been reduced to a splint. It never reaches the ankle region, while the two ankle bones are "engulfed" by the rapidly growing tibia and fuse with it. Thus, modern birds develop a single structure (the tibia with ankle bones fused to it and the rudimentary fibula at its side), articulating with bones of the foot below.

Hampé reasoned that the fibula might well maintain its capacity for attaining full, ancestral length, but that competition for material by the rapidly growing tibia mght deprive it of any opportunity to express this potential. He therefore performed three types of experiments, all directed toward giving the fibula some relief from its imperialistic and normally victorious neighboring bone. In all cases, the fibula attained its ancestral length, equal to the tibia and reaching the ankle region below. In the first, Hampé simply grafted more embryonic tissue into the region of the growing leg bones. The tibia reached its characteristic length, but the region now had enough material "left over" for the fibula. In the second, he altered the direction of growth for tibia and fibula so that the two bones did not remain in intimate contact. In the third, he inserted a mica plate between the two bones; the developing tibia could no longer "grab" material from its less vigorous neighbor and the fibula achieved its full length.

Thus, Hampé re-created an ancestral relationship between two bones by a series of simple manipulations. And this alteration engendered an even more interesting consequence. In normal chicks, the fibula begins its growth in contact with one of the small ankle bones below. But as the tibia enlarges and predominates, this contact breaks at about the fifth day of development. The fibula then retreats to form its splint, while the expanding tibia engulfs both ankle bones to form a single structure. In one case during Hampé's manipulations, the two ankle bones remained separate and did not fuse with either tibia or fibula (while both ankle bones fused with the tibia, as usual, in the other leg of the same embryo—an untreated control allowed to develop normally). In this bird, Hampé's simple manipulation not only produced its intended result (expression of an ancestral relationship in leg bones); it also evoked the ancestral pattern of ankle bones as well.

Hampé was able to produce these impressive atavisms by simple manipulations that amount to minor, quantitative changes in timing of development or placement of embryonic tissue. Adding more tissue doesn't simply make a bigger part with the same proportions; it leads to differential growth of one bone (the fibula) and a change in arrangement of the entire ankle area (two ankle bones, articulating separately to tibia and fibula in some cases, rather than a single tibia with ankle bones fused to it).

Developmental patterns of an organism's past persist in latent form. Chicks no longer develop teeth because their own mesenchyme does not form dentin, even though their epithelium can still produce enamel and induce dentin in other animals. Chicks no longer develop separate ankle bones because their fibula no longer keeps pace with the tibia during growth, but the ankle bones develop and retain their identity when fibulas are coaxed to reach their ancestral length. An organism's past not only constrains its future; it also provides as legacy an enormous reservoir of potential for rapid morphological change based upon small genetic alteration.

Charles Darwin constructed his theory as a two-stage process: variation to supply raw material and natural selection to impart direction. It is frequently (and incorrectly) stated that he said little about variation, embarrassed as he was by ignorance about the mechanism of heredity. Many people believe that he simply treated variation as a "black box," something to be assumed, mentioned in passing, and then forgotten. After all, if there is always enough variation for natural selection to use, why worry about its nature and causes?

Yet Darwin was obsessed with variation. In his writings he devoted much more attention to variation than to natural selection, for he knew that no satisfactory theory of major evolutionary change could be constructed until the causes of variation and the empirical rules of its form and amount had been elucidated. His longest book is devoted entirely to problems of variation—the two-volume *Variation of Animals and Plants Under Domestication* (1868). Darwin felt that atavism held the key to many mysteries of variation, and he devoted an entire chapter to it, closing (as I will) with these words:

> The fertilized germ of one of the higher animals . . . is perhaps the most wonderful object in nature. . . . On the doctrine of reversion [atavism] . . . the germ becomes a far more marvellous object, for besides the visible changes which it undergoes, we must believe that it is crowded with invisible characters . . separated by hundreds or even thousands of generations from the present time: and these characters, like those written on paper with invisible ink, lie ready to be evolved whenever the organization is disturbed by certain known or unknown conditions.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

THE NIKON FE
A CAMERA TO STIR YOUR EMOTIONS

A favorite of professionals, the FE is the creative camera par excellence – the embodiment of Nikon sophistication.

Its precise meter system sets correct exposures with uncanny accuracy, automatically. Or, just turn a dial for complete manual control. Either way, the pictures are razor sharp... pure Nikon.

Offering combined capabilities found in no other automatic, it accepts Nikon's extraordinary lenses, accessories and a true 3.5 fps motor drive.

A modern 35mm classic, the Nikon FE is the finest compact automatic in its class. Priced to make it an irresistible value too! Why settle for anything less.

# Winners of Natural History's 80th-Anniversary Photographic Competition

"You're kidding!" was the typical response of the winners of our 1980 Photographic Competition, suggesting that the many entrants (who submitted up to five pictures each) did so with little thought of succeeding. But the mail that piled up in our office was ample evidence that our contestants were cautiously optimistic.

This year our judges were Will Hopkins, former art director of *Look*, who is the art director of *American Photographer* and a consulting editorial art director; Arthur Rothstein, director of photography for *Parade*, the Sunday newspaper magazine, who recently had the distinction of serving as a juror for the 1979 Pulitzer Prize in photography; and Marie Schumann, picture reporter for *Life* and also a freelance picture researcher.

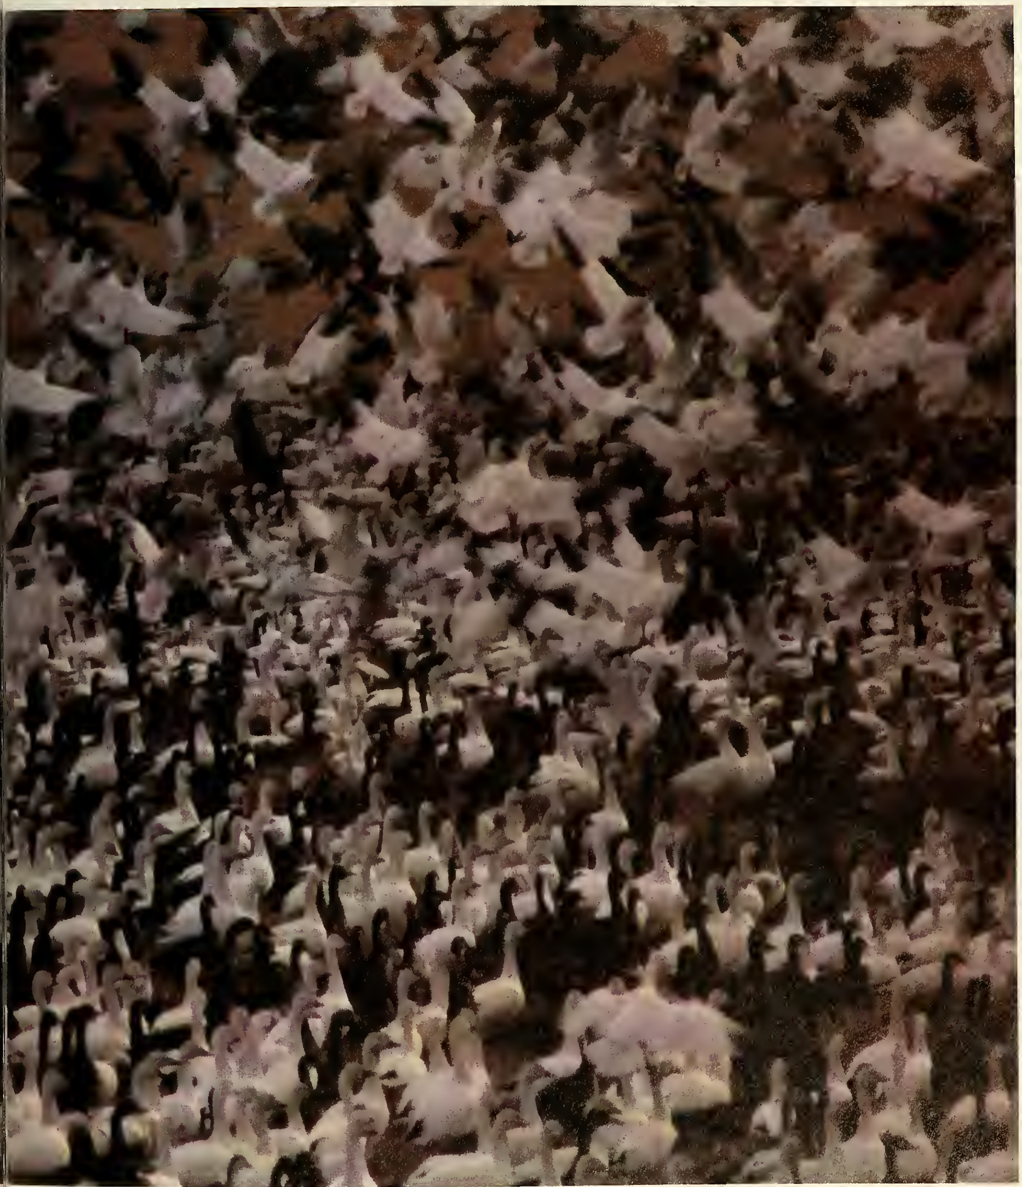
Artistic design figured strongly in the judges' selections; they bestowed the Grand Prize on a beautifully composed photograph of a yucca plant in white sand. First Prize winners were chosen for three major categories—The Human Family; Animals; and Plants and Their Environment—and Merit Awards were given for Photomicrography; A Sequence in Nature; Urban Wildlife; and Humor in Nature. Honorable Mentions were chosen from among all the finalists. The prizewinning photographs will also be exhibited at the Museum this fall.

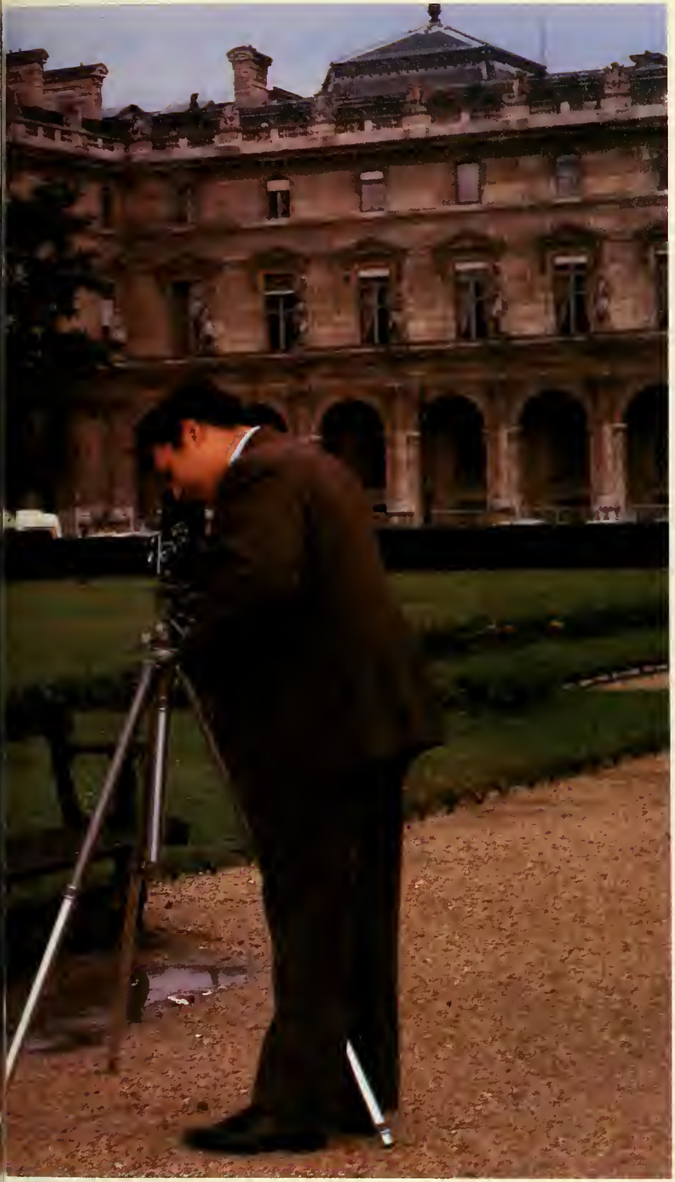
To all who participated, a well-deserved "thank you" and hearty encouragement for next year's contest. The deadline and rules for the 1981 competition, to be announced in a future issue of *Natural History*, will include one important new feature. In place of a Merit Award for Urban Wildlife there will be a special category for photographs more than fifty years old (you need not be the original photographer). So start looking through your family albums and attics for previously unpublished, historical pictures that fit the themes of our contest categories. We look forward to sharing your discoveries.

*Vittorio Maestro*

**FIRST PRIZE**
Animals
**FRANS LANTING**

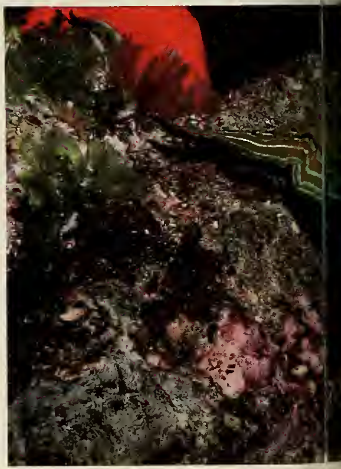
*Snow geese and Canada geese feeding at California's Tule Lake will take off at the slightest provocation. Frans Lanting photographed the birds in the late afternoon of an overcast winter day. He is an instructor in environmental studies at the University of California at Santa Cruz.*

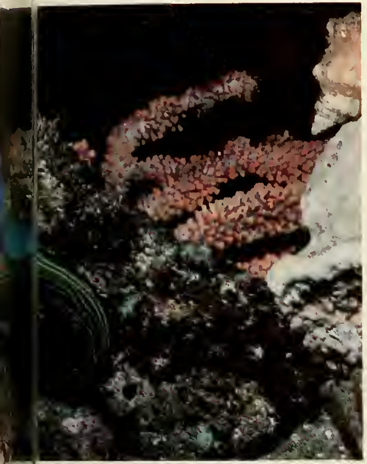




**FIRST PRIZE**
The Human Family
**IRENE BORGER**

*The Louvre in Paris provided the backdrop for this photograph, taken in the summer of 1972 by Irene Borger. A resident of Santa Monica, California, Borger is a dance anthropologist, interested in understanding dance in its cultural context. She also writes about photography, but does only a limited amount herself, as a hobby.*





## MERIT AWARD

A Sequence in Nature

**ALEX KERSTITCH**

*Alex Kerstitch first suspected that the sea slug* Roboastra tigris *was cannibalistic when he was diving in the Sea of Cortez. He had collected three specimens in a jar, but when he opened the container, he found only one oversized slug. To witness and record the event in nature, Kerstitch spent more than 100 hours underwater in the Gulf of California, off western Mexico. In this sequence, the smaller sea slug uses its sense of smell to approach the larger individual, probably expecting to make a meal of it. However, the larger sea slug turns on the smaller one, expanding its mouth parts to seize it. The victim is quickly engulfed and within thirty seconds has all but disappeared. One distended sea slug remains, and digestion begins. Although cannibalistic,* R. tigris *appear not to prey on other species of sea slugs, which they avoid. Alex Kerstitch is a research associate in the Department of Ecology and Evolutionary Biology at the University of Arizona, Tucson, and teaches high school art and science.*

# An Extravagance of Species

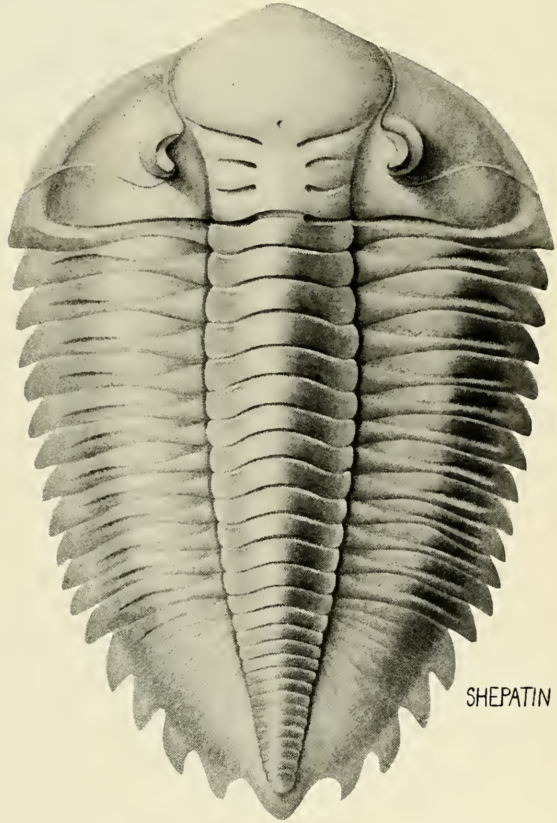
*The diversity of fossil trilobites poses a challenge to traditional evolutionary theory*

**by Niles Eldredge**

In the summer of 1972, a colleague asked me to help with a routine identification of a fossil owned by LeGrand Smith, an American missionary living in Bolivia, who was passing through New York en route to Czechoslovakia with a load of fossils. The single specimen he brought us resembled nothing so much as a rounded lump of hardened clay, and we first pronounced it "inorganic." But a thin ridge with what looked like the lenses of the eye of a trilobite (an extinct relative of crabs and shrimp) finally convinced us that there must be something organic hidden inside.

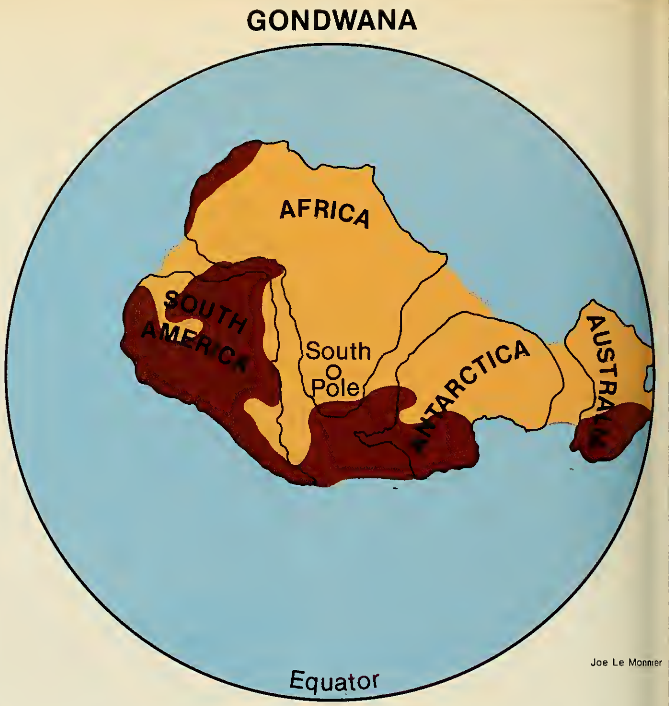
A month of tedious, painstaking preparation with a sharp needle eventually uncovered a fossil, although not a trilobite. It was so odd that we couldn't tell exactly what kind of fossil it was. After some detective work in the literature we finally established that it was an exquisite, uncrushed specimen of a rare proto-horseshoe crab. Only three highly distorted and totally flattened specimens even remotely like the Bolivian creature had ever been seen before. The crushed specimens came from Lower Devonian slates of southern Germany. Because of the excellent preservation of the Bolivian material, anatomical details of this group of early horseshoe crabs were clarified for the first time, which enabled us to reassess the early stages of evolution of horseshoe crabs.

But the really appetizing part of the encounter with Smith was his offhand assertion that he had thousands of Devonian fossils in his collection. His collaborator, Dr. Leonardo Branisa, then of the Bolivian Geological Survey, had amassed a still larger collec-



*Metacryphaeus*

*Scientists believe that about 380 million years ago, Africa, South America, Antarctica, and Australia were part of one unified landmass—Gondwana—which later drifted apart. The brown-shaded areas were shallow seas overlying parts of Gondwana; yellow indicates land; and blue, open sea. The trilobites discussed in the article inhabited these shallow seas; their fossils are now found in parts of South America and the other continents that were once under water.*



Joe Le Monnier

tion and had recently sold several thousand specimens to the Smithsonian Institution. No paleontologist even remotely interested in the fossils of a region could ignore or resist the promise of an open pipeline into what looked like enormous fossil wealth. Smith, Branisa, and I joined forces, and I soon found myself inundated with Bolivian trilobites.

Nothing delights a paleontologist more than confronting a rich collection of well-preserved fossils, and the Devonian rocks of the southern continents, the source of my trilobites, are famous for their fossils. They have been studied sporadically, mostly by northerners, for more than 100 years and until recently seemed fairly well known. Famous collecting sites in Bolivia, Brazil, and South Africa have long since been carefully picked over, and descriptions of their fossils have filled the pages of at least fifty articles and monographs. But now that remoter areas, particularly of the South American Andean Cordillera, are being frequented by fossil hunters, we find that we have only scratched the surface.

A flood of new fossils has easily doubled the number of known species of marine invertebrates. But beyond the simple pleasure of filling a large gap in our knowledge of the history of life, this new fossil material has raised a number of questions about the origin and history of a vast territory of the world and its inhabitants during a forty-million-year period of time that spans the Upper Silurian and Lower Devonian periods, from about 410 to 370 million years ago.

The area involved is the more southerly part of famed Gondwana, the once-unified landmass that drifted apart to become South America, Africa, Antarctica, India, and Australia. And the animals involved are shelled invertebrates—past denizens of shallow marine habitats. Dominant among these invertebrates are the trilobites.

Trilobites, including the ones from Bolivia that I studied, pose some fundamentally important evolutionary puzzles, puzzles whose solutions demand changes in evolutionary theory. It would be tempting to offer a scientific detective story of my work, with patterns in the raw data suddenly emerging to suggest a new theory. But no scientist ever accumulates facts blindly. There are always new ideas emerging that influence the way we look at new, and old, facts.

When I first became aware of the Devonian trilobites of the Southern Hemisphere, new ideas of the earth's history, such as the notion of continental drift, were in the breeze. These ideas were having their effect in other areas, particularly on explanations of how animal and plant distributions change through time (historical biogeography). And I was entranced with a new and, in some respects, radically different way of thinking about the evolutionary process that questions the role of natural selection in creating new species.

Theoretical ferment on evolution in the Southern Hemisphere is not new. The history of research in the ancient geography and the fossil animals of the southern continents has been tortuous and filled with controversy. To begin with, the notion that Africa and South America were previously joined has only recently gained widespread acceptance. For years, just a few solitary voices supported this idea, including those of the South African Alexander du Toit and the American Kenneth Caster, both of whom were familiar with the similarity between the fossil faunas of South America and southern Africa. Others believed the continents had always been far apart.

Depending on which view of geographical history is adopted (stable continents always separated or Gondwana now fragmented), paleontologists naturally develop rather different ideas about the history of distributions of animals and plants. If the pattern to be explained is the presence of similar organisms on two forever widely separated continents, our explanation invokes long-distance dispersal over the barrier of the South Atlantic. For marine invertebrates, we must invoke current patterns capable of wafting larvae long distances. The invention of these current patterns sometimes stretches he principles of oceanography beyond endurance.

Dispersal need not be invoked if we let the continents do the moving. In his approach, major changes in the distributions of organisms over the globe are passive reflections of actual changes in the physical geography itself.

Thus we have two conflicting sets of explanations for historical changes in animal and plant distributions; both have come into play in the analysis of the history of the 380-million-year-old fossils from the Southern Hemisphere. Now there is a consensus that the similar fossil faunas scattered over the southern continents reflect fragmentation of Gondwana rather than long-range larval dispersal.

What is the evolutionary history of he Gondwana trilobites? Most, roughly thirty of fifty genera, belong o the Calmoniidae, a single family hat occurs nowhere else and whose numbers offer an excellent chance to look for evolutionary patterns.

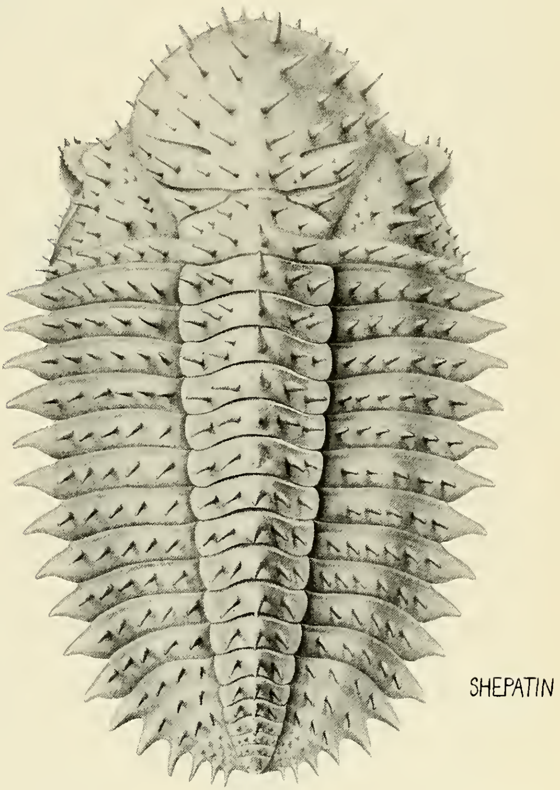
Apart from their dominance, the calmoniid trilobites are a fascinating lot. Derived from a garden variety, run-of-the-mill simple form, the sixty or so species known to date diversified into one of the more spectacular radiations of the entire 400-million-year history of trilobites. A few retained the general ancestral simple form. But most modified the old form, and some became, even by trilobite standards, downright bizarre. I have calmoniids with spines added to the front, or to the sides and middle of the head, or around the margins of the tail. I have others up to seven inches long—quite a length for a trilobite, most of which are less than one and a half inches long.

One group, which seems to be natural (meaning that all its members are closely related and form a single sublineage of the family), invented a unique anatomical plan. The genera in his group do not resemble any other kind of trilobite particularly closely. They are immediately identifiable as unique forms. *Deltacephalaspis*—the long name simply means "triangular-shaped head with spine"—is both typical of this group and highly unusual for trilobites in general. The immense spines sticking out from both sides of he head are particularly noteworthy. To guess with any certainty about how trilobites lived is difficult in itself, as their appendages, used for food gathering and locomotion, are almost never preserved. But I am totally at a loss to explain strange structures like the pair of enormous, hornlike spines on either side of the head of *Deltacephalaspis*.

The spines could have been stabilizing structures used in swimming or in righting the animal if it were ever tipped over. (Think of the difficulty a wingless insect has in getting back on its feet after falling on its back.) But with no clear living analogs, such speculation, however entertaining, is fruitless. For *Deltacephalaspis* and its relatives (such as the spine-snouted *Schizostylus* and *Cryphaeoides*), we must be content with just describing the array of different kinds, assuming that there were functional reasons underlying their evolutionary development.

The evolutionary pattern of diversification in the other major calmoniid group is more readily explained—at least in general terms. Also evolutionarily natural and coherent, this group shows, if anything, an even greater range of anatomical configurations than the first. But the kinds of anatomical modifications developed by members of this group are rather familiar. They are reminiscent of trilobites in other families. *Bouleia dagincourti*, for instance, is similar to *Phacops*, a trilobite that is also found in Gondwana.

I stumbled on this similarity before I became deeply involved with the Bolivian fossils. At the time, I was working on *Phacops* (see "A Trilobite Odyssey," *Natural History*, October 1972). Browsing through the trilobite collections at the American Museum of Natural History, I found a particu-



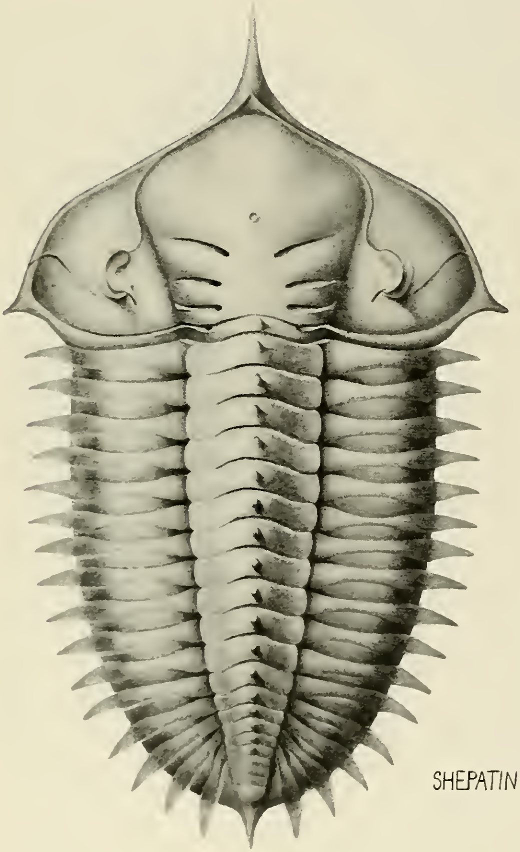
*Bouleia*

larly beautiful specimen of *Bouleia*, which was said to be closely related to *Phacops*. The specimen was well enough preserved to show that its resemblance to *Phacops* was entirely superficial. The only special similarities between them were a large, bulbous head and a small, rounded tail. Here, apparently, was a case of evolutionary convergence, in which remotely related organisms evolve somewhat similar structures, adapting to similar environmental demands.

In this second group of calmoniids there are several examples of convergence. *Metacryphaeus*, a calmoniid, is very much like the dalmanitid trilobites common in Devonian faunas elsewhere in the world. Another case of convergence is the similarity of *Schizostylus*, with its long snout and cheek spines, to the rare *Probolops*, both calmoniids. The head of *Probolops* is modified into exactly the same form as *Schizostylus*. Since the two are found in the same beds and *Probolops* is extremely rare, it may well have gained some advantage by mimicking *Schizostylus*.

Such similarities offer some insight into the evolutionary history of the Gondwana trilobites. But we are left to explain the most striking fact about these fossils—their diversity. What does all this variety suggest? How and why did ancestral trilobites evolve into so many kinds of descendants, so anatomically varied?

Standard evolutionary theory focuses on anatomical change through time by picturing natural selection as the agent that preserves the best of the designs available for coping with the environment. This generation by generation process, working on small amounts of variation, is thought to change, slowly but inexorably, the genetic and anatomical makeup of a population.



*Cryphaeoides*

If this theory were correct, then I should have found evidence of this smooth progression in the vast numbers of Bolivian fossil trilobites I studied. I should have found species gradually changing through time, with smoothly intermediate forms connecting descendant species to their ancestors.

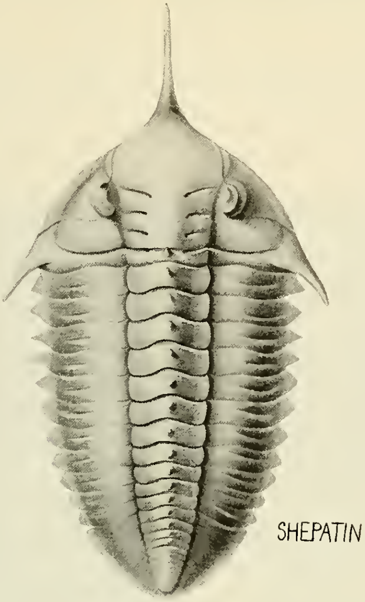
Instead I found most of the various kinds, including some unique and advanced ones, present in the earliest-known fossil beds. Species persisted for long periods of time without change. When they were replaced by similar, related (presumably descendant) species, I saw no gradual change in the older species that would have allowed me to predict the anatomical features of its younger relative.

The story of anatomical change through time that I read in the Devonian trilobites of Gondwana is similar to the picture emerging elsewhere in the fossil record: long periods of little or no change, followed by the appearance of anatomically modified descendants, usually with no smoothly intergradational forms in evidence.

If the evidence conflicts with theoretical predictions, something must be wrong with the theory. But for years the apparent lack of progressive change within fossil species has been ignored or else the evidence—*not* the theory—has been attacked. Attempts to salvage evolutionary theory have been made by claiming that the pattern of stepwise change usually seen in fossils reflects a poor, spotty fossil record. Were the record sufficiently complete, goes the claim, we would see the expected pattern of gradational change. But there are too many examples of this pattern of stepwise change to ignore it any longer. It is time to reexamine evolutionary theory itself.

There is probably little wrong with the notion of natural selection as a means of modifying the genetics of a species through time, although it is difficult to put it to the test. But the predicted gradual accumulation of change within species is seldom (if ever) encountered in our practical experience with the fossil record.

The problem appears to be this: focusing attention purely on anatomical



*Schizostylus*

(and underlying genetic) change ignores a fundamental feature of nature—the existence of species. Species are reproductive communities. They are held together by a network of parental ancestry and descent and separated from other, similar networks of parentage. They are coherent entities in space and—and this is the crucial part—through time as well. Species have origins, histories, and extinctions. They may or may not give rise to one or more descendant species during the course of their own existence.

The internal cohesion of a species predicts the sort of lack of anatomical change during its history that we see so often in the fossil record. And speciation, the process of creating a new, descendant reproductive community from an ancestral one—in a way other than that proposed by natural selection—must be a crucial step in the evolutionary process.

There are three or four commonly accepted, slightly different notions on how speciation occurs. The most favored theory of speciation for active, complex animals such as trilobites is geographical, or allopatric, speciation—what nineteenth-century biologists called vicariance. The basic idea of this model is simple: the easiest way to achieve reproductive independence between an ancestral species and its descendant is to segregate a segment from the main part of the ancestral species. Speciation occurs if enough behavioral or anatomical differences develop to guarantee that the two species will not hybridize should they one day come to inhabit the same area.

Other speciation theories hypothesize ways in which a new reproductive community—a fledgling species—can bud off from its parent without being isolated geographically as an initial step. But none of the various theories see *natural selection* changing a species' adaptations enough to develop a "new" species from an old one. Rather, speciation is a largely accidental fragmentation of a once coherent reproductive community.

During such events, behavioral, anatomical, and genetic change (sometimes quite rapid) may occur. Such change must occur if we are to be able to tell the daughter species from the parent. And the process of natural selection must account for part of such change. But natural selection per se does not work to create new species. The pattern of change in so many examples in the fossil record is far more a reflection of the origin and differential survival (selective extinction) of species than the inexorable accumulation of minute changes within species through the agency of natural selection.

The evolutionary pattern of the calmoniid trilobites is decisive: an evolutionary theory that maintains the primacy of pure natural selection and entertains no other mode of change is incomplete. In fact, the Devonian trilobites of Gondwana support, on several levels, the importance of geographical differentiation and speciation emphasized so long ago by Darwin and some of his contemporaries. First, speciation is the key to understanding the pattern of anatomical change actually seen in the fossil record. Since geographical isolation is the simplest way to bud off a descendant from an ancestral species, we look for adjacent regions harboring slightly different, closely related races and species. Within Bolivia itself, there is a pattern of geographical variation from north to south among many of the calmoniid species.

On a grosser level, three major subregions of the Devonian Gondwanan province can be recognized, each with its characteristic assemblage of species related to, but usually not the same as, those in the other subregions. Patterns of relationship among the species of calmoniids indicate that the Andean subregion may be more closely affiliated with southern Africa than either is with the stable continental interior subregion of South America. The Gondwanan map shows a possible explanation for this pattern: current patterns reconstructed on the basis of principles of physical oceanography indicate a more complete connection between the Andes and southern Africa than between either of those areas and continental South America.

Finally we return to the grand pattern we took up at the outset: the entire Gondwanan province is unique. It is an area that was so isolated from the rest of the world that it peopled its seas almost entirely with its own home-grown products. There is no clearer picture of the relation between geography and evolution than the pattern of the origin, history, and demise of the Devonian trilobites of ancient Gondwana. □

# Those Salmon Keep Butting Those Dams

*The Columbia River has become a virtual lake as dam after dam impedes its flow. For the salmon that spawn in the river, the dams may be insurmountable obstacles*

**by Anthony Netboy**

In April 1978, Herman J. McDevitt, a member of the Pacific Fishery Management Council, requested that the National Marine Fisheries Service review the status of the rapidly declining spring and summer chinook salmon runs in his home state of Idaho. The inquiry, under the Endangered Species Act, was later widened to include all salmon species in the streams above the confluence of the Columbia and Snake rivers. If after public hearings it is found that one or more of the upper river species are in danger of extinction, the federal government, along with the states involved, would be required to develop protective regulations "necessary and advisable for conservation of the species."

Endangered listing would automatically prohibit the taking of the species until stocks are built back—a process that could take years. It would also throw a monkey wrench into the operation of upper river hydroprojects, which have depleted the salmon stocks by usurping the water flow needed for the migration of these fish.

How did the Columbia, one of the world's richest salmon rivers, come to this pass?

The early explorers of this region found a wilderness whose rivers teemed with fishes, of which the salmon and steelhead trout (the Pacific version of the Atlantic salmon) were the largest and most numerous. The *Journals* of Lewis and Clark describe with considerable detail the scenery, inhabitants, rivers, and especially the wildlife they encountered in 1805 and 1806. In one day's sailing down the Columbia they passed twenty-nine lodges below the entrance of the Snake River, its major tributary, where Indians were catching and drying salmon. Outside nearly every lodge hung racks of drying fish. In some places the Indians were making pemmican (pounded, dried salmon) and packing it in baskets made of grass and rushes and lined with the dried skins of large salmon. These 90- to 100-pound baskets were not only the major item in the Indians' winter supply of protein food but also the chief article of commerce with distant tribes. At one village Clark counted 107 such baskets containing at least 10,000 pounds of pemmican.

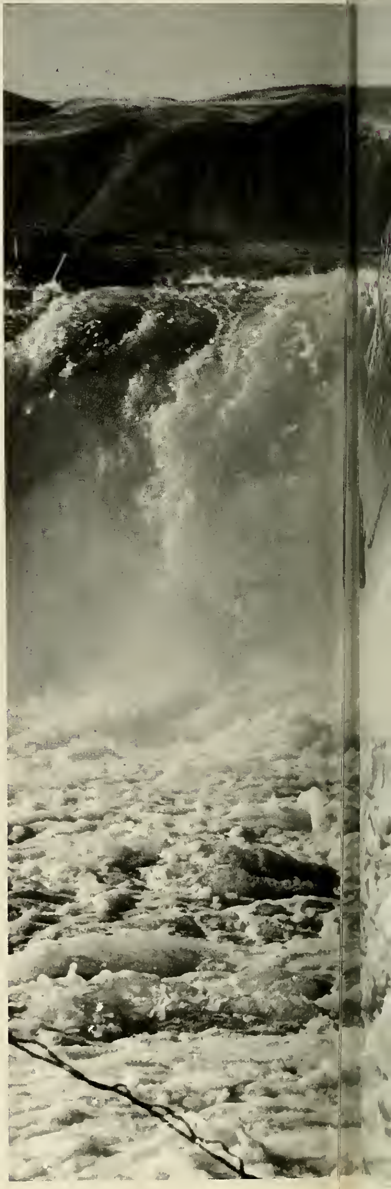
Lewis and Clark recorded more than a hundred sites where the Indians fished for salmon with a variety of gear. Catches were ample, especially at waterfalls, where salmon leaped up from the churning water and Indians with dip nets fished from treacherous rocks. The fish runs continued from April to October.

The salmon were the Indians' staff of life. These torpedo-shaped fish returned with astonishing regularity to the same streams every year. "What was more logical,"says anthropologist Philip Drucker, "than to imagine that they ascended the rivers to benefit mankind, died, and returned to life?"

Thus arose the belief that salmon

> were a race of supernatural beings who dwelt in a great house under the sea. They went about in human form, feasting and dancing like people. When the time came for the "run" the salmon people dressed themselves in salmon flesh, that is, assumed the form of fish to sacrifice themselves. Once dead, the spirit of each fish returned to the house beneath the sea.

To show their gratitude, joy, and relief, the Indians greeted the arrival of the first fish in the spring with prayers and incantations, for if the fish did not appear in sufficient numbers, hunger was sure to follow. Virtually every tribe that lived along the rivers from Bristol Bay, Alaska, to Monterey Bay, California, developed



*Netting salmon at Celilo Falls is a thing of the past. Construction of The Dalles dam ten miles downstream has flooded this once turbulent and productive stretch of the Columbia River.*

Ray Atkeson

LIFE HISTORY OF THE COLUMBIA RIVER SALMON AND STEELHEAD TROUT

| Common name | Chinook, King | Blueback, Sockeye, Red | Chum, Dog | Silver, Coho | Steelhead Trout |
|---|---|---|---|---|---|
| Length of freshwater life | few days–2 yr | few days–3 yr | few days | 1–2 yr | 2 yr |
| Length of ocean life | 1–5 yr | ½–4 yr | ½–4 yr | ½–1½ yr | 2 yr |
| Length at maturity | 3 ft | 15–33 in. | 25 in. | 24 in. | 26–28 in. |
| Weight at maturity | 22 lb | 5–7 lb | 8–9 lb | 10 lb | 6–8 lb |
| Spawning months | Aug.–Sept. | July–Sept. | Sept.–Nov. | Sept.–Dec. | Feb.–May |
| Female Fecundity (Number of eggs) | 5,000 | 4,000 | 3,000 | 3,500 | 3,000–3,500 |

rituals and taboos in handling and eating the first arrivals, as a means of propitiating them and their spirits.

The Indians apparently did not know that salmon are anadromous. Born in freshwater, where they remain anywhere from a few weeks to two or three years, salmon head for the ocean when they weigh only a few ounces. Biologists believe the salmon follow routes inherited from their ancestors and imprinted in their chromosomes. Their extensive ocean peregrinations may cover thousands of miles, but when they feel the mating urge, salmon head for their home rivers where they will spawn—and die. (Some steelheads survive and return to the sea.)

After the Indians were relocated to reservations in the mid-nineteenth century, large-scale commercial fisheries arose on the Columbia. The first cannery in the region—at Eagle Cliff on the Washington side of the river—was built in 1865 by Andrew Hapgood and the Hume brothers, all from Maine. That year they handpacked 4,000 cases of 48 one-pound cans of salmon; the next year, 18,000 cases. Competitors soon moved in to exploit the "river of gold."

As demand for this inexpensive, nutritious food developed in the United States, Europe, and South America, industry expanded to satisfy it—on the Columbia, Sacramento, and Fraser rivers, in Puget Sound, and in many Alaskan streams. By 1889 thirty-nine canneries on the Columbia and some of its tributaries were packing 630,000 cases a year.

In the heyday of the fishery an armada of fishing boats plied the Columbia from Astoria to Celilo Falls and beyond. In 1889 twenty-six hundred rowboats and sailboats fished for salmon in an area of about 150 miles, while purse seines, traps, setnets, dip nets, and most efficient of all, huge fish wheels caught additional thousands of fish a day.

Fishing was unrestrained. When reliable gasoline motors came along, in about 1912, many fishermen found they could catch more fish in the ocean beyond the treacherous Columbia Bar than in the river. From 1875 to 1920 annual catches averaged thirty to forty million pounds. At first only the hefty chinook, weighing from twelve to fifty and even one hundred pounds, were taken. When this species began to decline in the 1890s, fishermen hauled in the smaller species: silvers, or coho, weighing on the average ten to twelve pounds; chum, or dog salmon, eight to nine pounds; and red, or sockeye, salmon, five to seven pounds and regarded as the prime canning fish because of its deep red color and succulent flesh.

There were no minimum sizes to which fishermen had to adhere. What state regulations existed could not be enforced because of insufficient funds—only three wardens were available in the entire state of Oregon. One is therefore not surprised to read in the annual report for 1894 of the Oregon Fish Protector:

> It is only a matter of a few years under present conditions when the chinook will be as scarce as the beaver that once was so plentiful in our streams. . . . For a third of a century Oregon has drawn wealth from her streams but now by reason of her wastefulness and lack of intelligent provision for the future, the source of that wealth is disappearing and is threatened with annihilation.

It took a long time for the states of Oregon and Washington, which jointly manage the Columbia River fishery, to heed these prophetic words and take steps to slow down the pace of exploitation by outlawing the most effective gear—fish wheels, weirs, traps, and purse seines—reduce the size of gill nets and mesh, and curtail fishing seasons. Ultimately salmon fishing was limited to gill netting in the rivers, and trolling, a hook-and-line technique, in the ocean. All fixed gear was banned except for setnets, which by treaty rights only Indians may use on the Columbia.

By 1938, when 65-foot-high Bonneville Dam was completed, the fishery had already been considerably reduced by overfishing and much of the salmon's habitat in the vast watershed had been impaired by the clear-cutting of forests, by poor farming and grazing practices that caused soil erosion and siltation of streams, by logjams and logging dams, and by forest fires. Most harmful of all were the huge dams for irrigation, which were built without any consideration of the needs of migrating fish, and unscreened irrigation canals, which lured hordes of young fish to their death.

President Theodore Roosevelt in his *Autobiography* hailed the projects spawned by the passage of the Reclamation Act of 1902 as among the major achievements of his administration but ignored the damage they did to fish stocks. He said, "Many of the dams required for these huge tasks are higher than any previously built anywhere in the world. They feed main-line canals over 7,000 miles in length."

In *Development of the Water Resources of the Columbia River*, a comprehensive report published in 1947, the Bureau of Reclamation admitted "that much of the earlier development of water resources for the essential irrigation of lands in the Central Snake Basin was undertaken without full recognition of the significance of the salmon runs, or of the means to preserve them." As a result, "the volume of the runs has been reduced," a classic understatement. The report contained a map showing the extensive spawning areas already lost, including 1,100 linear miles in northern Washington and British Columbia blockaded by Grand Coulee Dam. When Grand Coulee became operational in 1942, it was the largest dam in the world, and no feasible means had been devised for getting salmon over a bar-

ricade 550 feet high, 4,173 feet long.

The completion of Bonneville Dam in 1938 had marked a new era in the history of the Columbia fishery. When designs for this multipurpose project were first published by the Army Corps of Engineers, no provisions had been made for fish passage. When this "oversight" was brought to the attention of the chief of the Corps, he allegedly said, "We do not intend to play nursemaid to the fish." Protests by the fishing industry and conservationists changed his mind, and the 65-foot megalith was provided with the most ingenious system of fish ladders, locks, and bypasses ever devised anywhere in the world. The fate of the greater part of the Columbia's anadromous fish runs depended upon the success of this novel system.

Milo Bell, the fishery engineer who, with the late Harlan Holmes of the Bureau of Fisheries, designed the ladders, wrote to me in 1970:

> Little was known of the number of fish that we might be expected to handle at the dam and only limited knowledge of the downstream migration that might be expected. It was assumed that the fingerlings would go over the spillway if their migration coincided with the period of high water that was in excess of power needs and would be allowed to spill; otherwise they would have to pass through the turbine blades in the power house. Passage through turbines was almost completely an unknown subject.

The upstream-migrating adults would be directed by means of powerful jets of water into the curving ladders, one on the Washington side of the dam and another on Bradford Island adjoining the powerhouse. After the fish were in the reservoir an attendant opened a gate and the fish continued their voyage upstream. "If you were a gambling man," said Bell, "you could have found some odds that the whole facility would not have been completely fuhctional."

*Aglow with lights that emphasize its engineering wizardry, Grand Coulee Dam blocks the Columbia River in Washington, diverting part of its flow to irrigation projects.*

The ladders went into operation in the spring of 1938 and the entire fishing industry watched with trepidation. But the canny fish found the entrances with seemingly little hesitation or loss. More than a million fish scaled the ladders that year, of which 470,000 were salmonids. In 1939, 522,000 were counted at the dam; in 1940, 740,000; in 1941, 670,000; and in 1942, 625,000. The large return of adults in 1942 was particularly gratifying because that year marked the end of the four-year chinook and red salmon cycle, indicating that the juveniles of these species, which went downstream in 1938 and 1939, over the spillway or through the revolving blades of the turbines, survived in respectable numbers, reached the ocean, and eventually returned as spawners. The Bonneville ladders were hailed in fishery circles around the world as a miracle of engineering and soon became a tourist attraction.

Although a study by the U.S. Fish and Wildlife Service in the late 1940s showed that up to 15 percent of the fingerlings and a smaller percentage of the adults were killed at the dam, the Corps of Engineers and the electric power industry, especially the public power agencies that had first call on Bonneville generation, proclaimed, "We can have fish and power, too!" This slogan, although challenged more and more as additional dams were constructed on the rivers, generally persuaded the people of the Pacific Northwest to accept the almost complete damming of the Columbia and Snake rivers.

The Corps of Engineers pushed hard to have Congress authorize mainstem dams proposed in its famous "308 Report," first published in the 1920s and subsequently expanded. The Corps had surveyed every stream in the United States portion of the watershed that could feasibly be harnessed for power, navigation, irrigation, and allied benefits. In a similar study by the Bureau of Reclamation, the focus was on irrigation possibilities, the costs to be partly repaid by power generation, as at Grand Coulee, which has provided water to fructify about 500,000 acres in Washington.

The alarmed fishing industry demanded a moratorium on dam construction until more was known about the effects of Bonneville on the fish runs. The Fish and Wildlife Service's

Ray Atkeson

Ray Atkeson

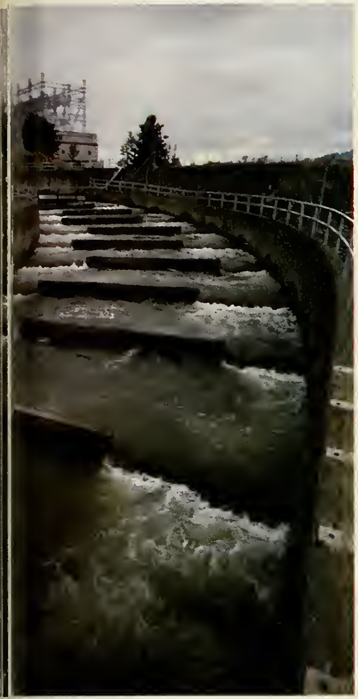
report was suppressed by the Secretary of the Interior, but its findings leaked out. The Columbia Basin Interagency Committee (CBIAC), consisting of the governors of all the basin states, held a hearing at Walla Walla, Washington, in June 1947, at which many people testified pro or con. The gist of the proponents' arguments for a moratorium was given by Thomas Sandoz, vice-president of the Columbia River Packers Association, who said, "Because one power dam is a good thing is no argument six are better." And a spokesman for the Fishery and Cannery Workers' Union added, "Since 75 percent of the salmon spawning areas [an exaggeration] are already lost, the lower Columbia River should be shielded from additional encroachments. Why spend the taxpayers' money for unwanted power, navigation, and reclamation projects before a fish [enhancement] program is fully developed?"

Speaking against the moratorium was Ira N. Gabrielson, chief of the U.S. Fish and Wildlife Service, who argued that the region needed the dams' power and other benefits. Gabrielson and Sen. Warren Magnuson of Washington, who sent a letter to the hearing, felt that the success of the Bonneville ladders augured well for getting fish over additional high dams. The CBIAC referred the issue to its parent body, the Federal River Basin Commission, which concluded unanimously that it did not favor the moratorium because "additional dams would not result in major loss or extinction of fish life in the streams."

In the June 1947 issue of the *Oregon Business Review*, Paul R. Needham, director of research for the Oregon Fish Commission, wrote:

> Some of the plans of the dam builders, if completed, will completely ruin for all time some of the richest fishery resources of the nation. The principal streams concerned are the Sacramento in California, the Rogue in Oregon, and the Columbia with its principal tributaries in Washington, Oregon, and Idaho. A total of some sixty-nine dam sites are now under study in the Columbia Basin alone. Among them is the McNary Dam [already authorized by Congress for construction across the main Columbia above Bonneville near the mouth of the Umatilla River]. If this is built, it will be the beginning of the end of steelhead and salmon runs in the upper Columbia. Another main-river dam is proposed for con-

David Falconer, Black Star



*On their way upriver to spawn, salmon must negotiate such natural obstacles as waterfalls and such man-made ones as the fish ladders at Bonneville Dam. The combination proves too much for some fish.*

struction at The Dalles near Celilo Falls. But the finishing touch will be the four-dam plan now being recommended by the Army Corps of Engineers for construction on the Snake River to provide slack-water navigation to Lewiston, Idaho. All western fishery biologists with whom I have talked agree that this plan, if followed, will spell the doom of salmon and steelhead migrations up the Snake River as well as up its tributary, the Salmon River in Idaho.

Needham's statements were remarkably prophetic.

In the next three decades the Corps of Engineers' dams went up in fairly rapid succession. On the Columbia: McNary, 100 feet high; The Dalles, 88 feet; John Day, 132 feet. On the Snake: Ice Harbor, 100 feet; Lower Monumental, 93 feet; Little Goose, 100 feet; and Lower Granite, 82 feet. All have Bonneville-type fish ladders. The Corps also built Chief Joseph Dam, below Grand Coulee, without ladders, eliminating another considerable portion of the salmonid habitat.

During the Eisenhower administration the federal government temporarily withdrew its interest in the main stems of the rivers and licensed public utility districts in Washington to build Wanapum, Priest Rapids, Rocky Reach, and Wells dams, all supplied with fish ladders. Idaho Power Company was permitted to construct a trio of dams on the Middle Snake: Hells Canyon, Oxbow, and Brownlee. Only Brownlee had fish-passage facilities, and when they failed, the entire Snake River system above the dam was lost to salmon and steelhead.

All the consequences of damming a mighty river teeming with valuable migratory fishes have occurred on the Columbia. Nowhere in the world have salmon had to cope with so many man-made difficulties; yet with the help of a tremendous hatchery program, some of the runs continue to exist in relatively respectable, if diminishing, numbers. Fish that spawn in the upper reach of the Columbia in Washington, such as the Okanogan River, must hurdle nine dams with accumulated elevations of over 800 feet in a stretch of about 500 miles. At each obstruction they must find the entrances to the ladders, adjust to conditions in the reservoir, and still have enough stamina to reach their destinations and spawn. Fish heading for Snake River tributaries, such as the Salmon and Clearwater, must pass eight dams with a total elevation of almost 800 feet; losses are great betwen dams as the fish die from exhaustion or from bubble disease generated by an excess of nitrogen gas in the reservoirs.

However, by far the greatest mortalities are suffered by the tiny fingerlings. The increasing demand for power has made the Bonneville Power Administration, which markets the electricity generated at all federal dams, and the public utility districts in Washington reluctant to taper off generation of energy in the spring during fingerling migration by allowing some of the water to flow through spillways. When the fingerlings can take this route instead of dashing through the turbines, their chances of survival are much greater. The losses at some dams have been so enormous in recent years—95 percent in the drought year 1977 on the Snake River—that extraordinary measures had to be taken. In 1979 some five million juveniles were collected at Lower Granite and Little Goose dams and transported by trucks (called fish pullmans), barges, and even airplanes for release below Bonneville. Survival rate by this means is said to be more than twice that of juveniles that go through the turbines.

"Extensive effort has been made to improve fish passage ever since Bonneville Dam was built," says William E. Pitney, a biologist with the Oregon Department of Fish and Wildlife.

> The resource management agencies of the several states have struggled with many problems. Improvements have been made, but for each gain an almost unending host of other problems has been recognized. Once it had been determined that adult fish could pass over high dams it was quickly discovered that their young were ineffective in finding their way downstream through many miles of slack water. This resulted largely from the water being impounded at the time of year the migrants should have been carried by the freshets to the sea. Some of those which do leave the reservoirs find only the turbine systems as outlets and are killed by pressure changes of spinning blades.

Thanks to the dams, the Columbia is now completely tamed from tidewater to the headwaters in British Columbia, except for about fifty miles of free-flowing water around the Hanford reservation, site of the greatest concentration of nuclear plants and nuclear-waste dumps in the world. Even here the Corps of Engineers has staked out its claim and despite intense opposition is hoping to build Ben Franklin Dam, for which it has already received planning money from Congress. The deep chasms and canyons, the thundering cascades, the huge rocks over which the river had beat endlessly when spring torrents came down from the mountains have all been drowned out. Most of the birds that used to feed and rest in the sloughs and channels—Canada geese, pelicans, many species of ducks, cormorants, eagles, condors, herons, and cranes—have either vanished or are seen in very small numbers. Deer and elk populations are sparse. There has not been a major flood since 1948.

Along the tidal portion of the river there are towns and cities, factories, mills, tank farms, aluminum smelters, and other industrial establishments.

Around metropolitan Portland the spoils of industry plague the Columbia and foul fishermen's nets. East of Portland, the brooding cliffs and rimrocks are unscarred, but the forests of Douglas fir and associated species have been gashed by huge clearcuts.

Above Bonneville, one dam and its reservoir succeeds another for 450 miles to the Canadian border, and the scene is repeated on the Snake River for several hundred miles. Spidery transmission lines, taking energy from the fifty-four major dams in the basin, connect the steel towers that march across the landscape in every direction and bring electricity to cities and villages, factories, farms, and isolated ranches, at rates that are a fraction of those in the Midwest or the East.

Development of the hydroelectric potential of the rivers has brought immense boons to the Pacific Northwest: low-cost power, a forty-foot navigation channel to Idaho, water to fructify millions of acres of semiarid land, and elimination of floods on the once turbulent Columbia. Offsetting these gains has been the loss of much of the salmon stocks.

Of the four species of salmon in the Columbia, the once abundant chum have totally disappeared, and the equally numerous red salmon have been reduced to token numbers. Coho had almost vanished from the river by 1960, then made a phenomenal comeback thanks to a breakthrough in salmon culture with the development of pellet feed. Now, for reasons biologists can't fathom, coho are again in serious decline all along the Pacific coast. Stocks of spring and summer chinook are at a nadir. Fall chinook is the mainstay of the commercial fishery and, along with coho, of the sport fishery. Winter steelhead runs are in fairly good shape; summer steelhead runs are not. The upriver races have experienced the most serious deterioration because of the difficulties of surmounting the many dams.

About half of all sport and commercial catches are the products of some fifty salmon hatcheries in Oregon, Washington, and Idaho. In the 1970s commercial landings, exclusive of ocean catches, averaged nine to ten million pounds a year, a quarter to a third of what they were fifty years earlier. The increase in ocean catches has not been substantial enough to make up the shortfall, and the canning industry on the Columbia is moribund—only 4,400 cases were packed by the four plants still in operation in 1978.

To retain as much of the anadromous fish stocks as still survive has been costly. More than $500 million has been spent by the federal and nonfederal power entities to construct ladders and other fish-passage facilities at the dams, and for salmon and steelhead hatcheries, research facilities, stream improvement programs, screening of irrigation ditches, and other works. This is by far the most ambitious and costly fish-saving undertaking anywhere in the world.

What of the future?

In 1979 two months were lopped off the ocean-trolling season, gill netting in the river was reduced to 55 days (compared with 272 days in 1938), the sport-fishing season was curtailed by a month, and the bag limit cut to two salmon a day from three last year. Still, too many fishermen were chasing too few fish, and all user groups were unhappy. The 300 to 400 Indians, belonging to four tribes that have a private fishing reserve on the Columbia by virtue of the Walla Walla Treaty of 1855, exacerbated the situation by filing one suit after another in the federal district court at Portland to curtail the white men's fishing season. They fear it would adversely affect their chances of catching 50 percent of the harvestable salmon that enter the river, as allowed by a court ruling.

In Oregon the retail price of salmon has reached $6.00 a pound, higher than the best cuts of beef. As part of a many-pronged effort to produce more fish, biologists say, "Give us more money and we will provide more salmon." On this assumption Congress has funded the building of hatcheries to make up the losses at the Snake and Columbia river dams. If Congress provides the funds, double the volume of fingerlings will be released into the streams, from 75 million to about 150 million annually. Whether these fish will fare better than their predecessors in getting past the dams is not certain. There is, however, plenty of habitat available to accommodate additional adult populations. Terry Holubetz, director of the Pacific Fishery Management Council, says that in Idaho alone there are some 3,500 miles of streams with clear, constant water and undamaged spawning areas.

Another approach to the problem is to persuade the electric power agencies to reduce generation at the dams when fingerlings move seaward in order to allow more of them to go over the spillways. As more powerhouses rise at these projects, however, the fear is that inevitably there will be so much capacity—to satisfy Gargantuan demands for electricity—that at times almost the entire flow of the Columbia will be run through the powerhouse at most projects, unless Congress forces the utilities to reduce generation and allow more fingerlings to pass over the spillways. This is a key provision in the Northwest Energy Bill now going through Congress—and it is being fought bitterly.

Water rights are allocated by the states for different uses but migratory fishes have never been accorded such rights. The Federal Power Commission, which licenses the dams, is sympathetic to the need of curtailing generation to save the fingerlings, and some progress has been made in persuading the Bonneville Power Administration and the public utility districts to reduce generation, a move that aided fingerling survival in 1977, 1978, and 1979. Fishery agencies are also urging the Bureau of Reclamation to reduce water withdrawals at some of its projects for the benefit of salmon migration and are opposing the Bureau's plan for irrigating some 500,000 additional acres with Grand Coulee reservoir water. They say that the region already has too much irrigation for growing sugar beets, potatoes, and dryland wheat, all of which are in excess supply in the United States.

If these and other proposals to ease the salmon crisis are not soon implemented, one cannot help but conclude that the upriver races face additional losses and perhaps, in the not too distant future, will be reduced to token populations. Should that happen, there will be few salmon and steelhead climbing the ladders at the dams, and the stocks will be almost entirely confined to the lower river, testimony to the folly of believing the engineers when they said, "We can have fish and power, too!" ☐

*From platforms over the water, Indians use the traditional dip net method to scoop up salmon. This fishing site is at the Cascade Locks on the Oregon side, upstream from Bonneville Dam.*

# Pink Stripe on the Ocean

In late August or early September, when there is a spell of calm weather near Bermuda, you can sometimes see one or more pink stripes on the water several miles offshore. They look as if they had been painted from the near to the far horizon with a giant brush. James Burnett-Herkes, director of Fisheries in Bermuda, told me that the pink material is coral spawn, consisting of motile larvae released by anthozoan octocorals, which float to the surface and are swept into a narrow band by down-welling convergence currents. If these larvae were to settle on a reef, they might grow into sea fans, sea feathers, or other soft corals. But the ones in this photograph were probably eaten by fish or crustaceans.

The convergence currents are caused by the evaporation of water in the shallow lagoons of the Bermuda platform during the summer. Warmer water would normally float on top of the colder water from the Sargasso Sea, but because the warm water has evaporated and become more saline, it has also become more dense. Thus, in calm weather in the late summer, shallow water can run slowly and smoothly off the edge of the platform into deep water, creating an amazingly sharp boundary. That boundary, which would otherwise be detected only by someone making a temperature or salinity survey, is made dramatically visible by the presence of the brightly colored coral spawn—the "paint" of this mysterious "highway stripe."

خلق
صنف خبازان

Just as the thick dark of the night was giving way to the pale light of early dawn, the ringing of the alarm clock shook Gulab out of his sleep. He hastily got out of his cot and, after making his ablutions, rushed to the local mosque. With a sigh of relief, he noted that other people were still arriving. He was keenly aware that some people were keeping a close record of his attendance, as well as other of his activities. As he mechanically performed the rituals, his mind wandered over the conflicting demands that were ripping his life apart.

Like everybody else in the mosque of Khost in southeastern Afghanistan, Gulab was born in the vicinity of the town. He was thirty or thirty-one years old. As dates of birth were not recorded, he did not know his exact age, but he knew the tribal lore well. He remembered the times spent with his father, memorizing the names of his seven paternal ancestors as required by custom. His father had made sure that Gulab and his three brothers knew the names of the various lineages and clans that jointly made up the Pashtun ethnic group. They were also told about the groups that were allied together and those that carried on feuds.

When Gulab was a boy, his father owned four acres of irrigated land and about forty watered by rainfall in a village fifteen miles east of Khost. He was also involved in the illegal trade between Khost and towns across the border in Pakistan. The biggest item of trade at the time was wood. Some of the now barren mountains were forested then, and others had a much

*In early September 1979, supporters welcomed home President Taraki from the Nonaligned Nations Summit in Havana. Taraki was deposed on September 16, and some days later his death was reported.*

Rick Smolan, Contact

thicker layer of green. But people had to make a living, and nobody was concerned about the changing nature of the scenery or the erosion that deforestation would precipitate.

In those years, Khost was not a particularly healthy place. It was infested with malaria, and the people preferred their cooler villages on the upper hills to the damp and flat valley in which the town was located. Few people wanted to settle in Khost for long. Yet, a government garrison had been stationed in the town since the mid-nineteenth century, and the governor of Paktia Province spent the winters in the town.

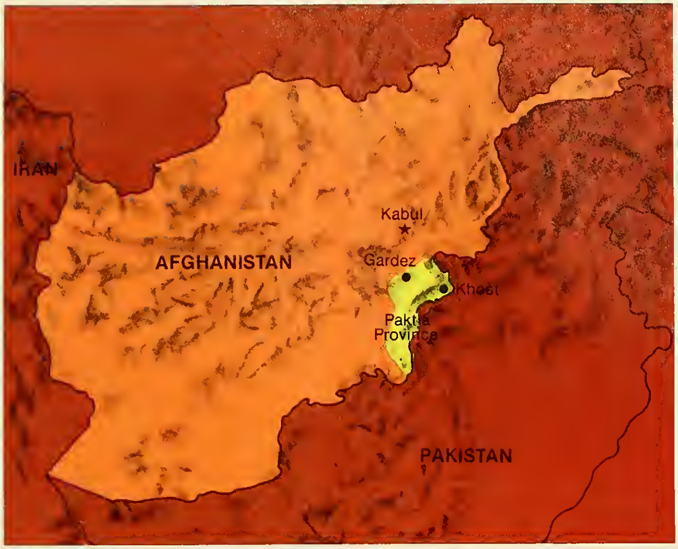
But it had not been Gulab's lot to avoid Khost. He remembered his first trip there well. One day when he was about six years old, he and his brother Sur Gul, who was a year younger, were told to put on their fine clothes and were taken to the town. In those days there were no trucks or buses linking the villages to the town, and the boys were put on a donkey while the older men walked. One of Gulab's two sisters was married to a man whose village was about two miles from Khost, and the brothers were at first told that they would be staying there for some time. In fact, they were to attend the school in Khost for the next six years.

Gulab's father was not literate. He had not allowed his eldest son to go to school and, as it later turned out, was not going to permit the youngest one to enroll either, but his dealings with the governmental machinery had convinced him that it might be useful to send his two middle sons to school. So in 1956 Gulab and Sur Gul found themselves in school.

The two boys were terrified by the discipline. Whenever they felt the need, teachers and headmasters used the stripped branch of an almond tree on the students. Most of the students were much older than the two brothers; some had spent two or three years in the same grade without learning to read or write. As the central government held the headmaster accountable for the number of enrollments per year—public schooling was in theory compulsory—those students unwilling to attend the classes were dragged there by the school's orderlies. A generous bribe to the headmaster was the only way their parents had to release them from their misery.

*In much of the Muslim world, the home compound has separate quarters for women, but this is not typical in Paktia Province, where women have more contact with the outside.*

Joe Le Monnier



After their pleas for returning to the carefree life of the village were rejected, Gulab and Sur Gul accepted the inevitable and passed their exams regularly. Despite their acclimation, they cherished their three-month summer vacations, which they spent in their home village, sharing in the schemes of their age-mates.

Graduation from the elementary school brought about a longer period of exile for the two brothers. Through some connections in Kabul, a member of their lineage learned that the government had established two special high schools for students of the border areas. Unlike other schools in the capital, in the special schools the language of instruction was Pashtu. In addition to room and board, students were granted a monthly stipend. The relative persuaded Gulab's father to enroll Gulab in one of the high schools and to send Sur Gul to a military school, also located in Kabul.

This time, the trip was longer and more strenuous. After tearful partings from their mothers, who entrusted each with a bundle containing clothes, some home-baked cookies, and a cone of refined cane sugar, a band of thirty boys from villages surrounding Khost headed toward Gardez, the provincial capital. Steered by five elders from different clans, the group took three days to walk the one hundred or so miles separating the two towns. They spent the nights in mosques or guesthouses of the various clans along the way. It rained on the last day of their trip, and when they reached Gardez not only were they soaked but the sugar in their sacks had melted, permeating all their clothes with a special smell. The owners of teahouses, which also served as guesthouses, refused to receive them at first until one of the elders accompanying them found a local friend who intervened on their behalf.

Gardez was much larger than Khost; its size and the number of soldiers pacing its streets awed the boys. They listened with fear as some shopkeepers described the methods of torture that the governor administered to those who dared defy his orders. However, the sight of the trucks on which they were to be taken to Kabul overjoyed them. The trucks were loaded with wood on which they had to sit, but this was the first time most of them were riding a vehicle, and they were thrilled at the prospect and pleased not to be walking. They sang Pashtu martial and love poetry and were amazed at the speed of their journey. The trucks were making about ten to fifteen miles an hour!

*Roads are the transportation backbone of Afghanistan, which lacks railroads and navigable rivers. Despite some upgrading of the highway system, travel conditions often remain as rugged as the land.*

Covered with dust from the dirt road, they reached Kabul after about ten hours' travel. Henceforth, Gulab's and Sur Gul's lives were to be intertwined with the rapid tempo of political change in the capital. Nobody had any inkling of what the future held in store, of course, and when he was taken to his room in the school and shown his bed, all that a tired Gulab desired was blissful sleep. The night was quiet, but with dawn the new adjustments began.

Life in school resembled that in a military barracks, and there were elaborate rules for what could and what could not be done. The rest of the city remained a great mystery to Gulab and his fellow students. On holidays and Fridays they walked around the town and even, at times, managed to see a movie, but they never made any real contact with the local people. Gulab slowly mastered the Persian language, but the opportunity to use it was basically confined to the classroom and his weekly rounds in the markets of Kabul. Gulab spent six years in the school, yet not once did he have a meal in a house. The only house he visited was that of the principal, but not for social purposes. The principal was building two new houses for himself, and to avoid hiring labor, he assigned teams of students to work on the site.

Eve Arnold, Magnum

In these years, Gulab's perception of Afghanistan underwent radical changes. Textbooks told him of an indestructible country that had managed to resist all attempts at annexation and conquest for some three thousand years. While he readily imbibed this part of the nationalist credo, he was more ambivalent about the portrayal of rural revolts. The textbooks painted an image of a progressive central government whose designs were destroyed by the bigotry of the rural people. Not far from his school was a monument, called the Minaret of Knowledge and Ignorance, which

celebrated the victory of the reforming government over the rebels of Khost in 1924. But Gulab had heard a different story in Khost. The elders of the village had told him that they had been resisting a despotic government's interference in their customs and its demands for revenue. At home Gulab himself had repeatedly sung some of the antigovernment poetry of the period. To say the least, he was confused by the discordance of the two versions.

During their three-month summer vacations, Gulab and his brother went back to their village near Khost. Transportation now reached the town, and the boys rode on the back of trucks. They were becoming adolescents, and there was talk of looking for suitable matches for them. As the last year of high school approached, the boys' family arranged their engagements to two girls from nearby villages. Since they had never seen the girls before, they spent long hours wondering what they looked like. Custom allowed the future mothers-in-law to arrange for the couples to meet without the knowledge of their hus-

*Men relax and confer in a teahouse in Paktia Province. Pashtuns, who make up more than half of Afghanistan's population, include tribes of sedentary agriculturists and nomadic herdsmen.*

Roland and Sabrina Michaud

bands, who played the role of stern patriarchs. Gulab and Sur Gul were finally permitted to see their future wives in the presence of their mothers, but nobody quite knew what to say, and they just stole glances at each other. By that time, vacation was over, and the boys had to return to school.

Life in school was suddenly transformed. A series of high school student unrests and widespread political agitation at Kabul University had erupted following Gen. Mohammad Daud's ouster as prime minister, a post he had held for about a decade. The movement had taken five years to reach Gulab's school, which was finally in the throes of overdue change.

Food in the school had always been bad. It was common knowledge among the students that part of the funds assigned to their upkeep was diverted to pay for the principal's new houses. Nobody had dared to complain, taking for granted that all government bureaucrats were corrupt. On hearing that the Ministry of Education had considered similar complaints from the students of Kabul University, some of Gulab's classmates decided to follow their example. They even convinced a number of students, including Gulab, to accompany them to the university to see for themselves.

This was Gulab's first visit to the university. He was amazed to see so many extremely well-dressed girls and boys and, at first, took them to be part of the staff, only to learn they were all students. A number had their own cars and others used chauffeur-driven governmental cars. When he expressed his surprise at this wealth, a friend commented that these students came from a class other than that to which people like Gulab and himself belonged. Seeing the expression of bewilderment on Gulab's face, the friend explained that the word "class" expressed the difference in wealth and social standing of different segments of society.

Gulab knew that in his village there were people called *mala*, which meant "filled with food," and those called *wigi*, which meant "hungry." He knew that the size of landholdings in Khost were unequal. But a considerable part of the land of one person, if not all of it, would not be enough to pay for one of the cars the students were driving. A thought suddenly flashed through his mind: If the sons displayed so much wealth, how wealthy must the fathers be!

The sight of the university made such an impression on Gulab that he could not absorb the advice he and the other students were given on how to voice their discontent. The idea of bringing their complaints to the Ministry of Education, however, was circulated among his fellow students, and although most were frightened, they all agreed that the situation was intolerable. A few days later, some students challenged the authority of the principal by refusing to eat their supper. Infuriated, the principal reacted by trying to beat one of them. Others came to his rescue, and a melee broke out between students and orderlies. Some teachers intervened, and soon a representative of the Ministry of Education arrived at the scene of the fight. After inquiries, which took almost a month, the school got a new principal, the food improved, and there was no more talk of working on housing sites in the evening.

Soon it was time to prepare for the entrance exam to the university. Only by accident did the students, who were familiar only with writing essay examinations by rote, learn that it was to be of the multiple-choice type. A

friend from the university volunteered to explain what this meant and even gave them a trial exam. When the examiners came from the university, they took only a couple of minutes to explain the procedure before administering the exam.

After some six months of anxious waiting, Gulab learned that he had been admitted to the School of Natural Sciences. He was granted a place in the dormitory, where he was to share a room with five other people, none of whom was from the vicinity of Khost. Two were Pashtu speakers, but the other three spoke hardly a word of it. Also, all professors lectured in Persian. Gulab made a strong effort to understand what was said in class, but he was acutely aware that the students from Kabul made fun of his accent. Not wishing to risk ridicule, he grew reticent in class and would not take part in discussions.

Life in the dormitory was different. Gulab thought it funny that he was becoming closer to his Persian-speaking roommates than to the Pashtu-speaking ones. These last two came from major land-owning families, and everybody was soon aware that they had used forged documents on their family income in order to qualify for the subsidies provided by the university. They carried sufficient cash to go regularly to restaurants and movies. When in a good mood, they even spoke of their exploits with women and told Gulab that they made regular visits to prostitutes. Gulab, who had never been told that one could have access to a woman outside the bounds of marriage, now realized there were many things he did not know and braced himself for future surprises.

Gulab's three Persian-speaking roommates came from a background similar to his own. One from the valley of Darwaz, in the province of Badakhshan, told Gulab that his village was right on the bank of the Oxus River, which bordered the Soviet Union. Gulab was amazed to learn that there

*Lumber is loaded for local use. Despite a harsh climate and terrain, Afghanistan has some luxuriant forests. Many have been depleted, however, by large-scale timber smuggling to neighboring Pakistan.*

Ralph Gates

was a large town on the Soviet side of the border and that it had an airport where some fifteen to twenty planes landed every day. Gulab had been to the airport of Kabul only once, but the description of the Soviet airport convinced him that it was much larger than the Kabul airport. And, he marveled, the airport of the Soviet capital must be even larger than that of a provincial town.

He also learned that people in Badakhshan spoke several languages and that Persian was not, in fact, his friend's mother tongue. It was the same with another of his roommates, who came from a small village in the province of Balkh, in northern Afghanistan, and whose mother tongue was Uzbecki. Only the third roommate, who came from Hazarajat in central Afghanistan, was a native Persian speaker, but even his accent was not like that of Kabul. Although the boys at first hesitated to trust each other, they gradually found that they had a lot in common. Other differences, however, came to the fore.

All were aware that there were students who were members of various political parties, and Gulab had even heard some of them deliver speeches on oppression and class struggle in a corner of the campus where a forum was regularly held. Toward the end of the first semester, one of these boys, who lived in the next room, approached Gulab and asked whether he would be interested in reading some of their literature. Gulab said he would not mind, and the student gave him three novels written in Pashtu by Noor Mohammad Taraki, who was to become president of Afghanistan some ten years later, after the coup of April 1978.

These books centered on the description of life in rural Afghanistan and of migrant Afghan labor in British colonial India. Religious dignitaries were condemned as parasites, and the consumption orientation of the rural and urban upper classes was deplored. But the books also had a positive message. In each one, the chief character was made to declare that if the working people united, they could put an end to this condition of inequality and abolish the whole stratification of society.

Gulab was favorably impressed and asked his contact for more material. Meanwhile he discussed the books with his three roommates. To Gulab's surprise, one of the boys told him that although the author claimed to be a socialist, he was in fact a Pashtun chauvinist and that most of his followers were Pashtuns. The second said that he could not possibly agree with an atheistic author, and that Islam, although abused like any other religion, was capable of being generated from within. True equality, he said, had only existed during the reign of the first four caliphs. The third one disagreed with all of them, declaring that the Soviet Union, which had inspired the author in advocating a method of peaceful struggle, was no longer revolutionary. He maintained that the only revolutionary country in the world was the People's Republic of China; that the only true harbinger of the future was the Maoist group in Afghanistan. Taken aback, Gulab did not know how to respond. When his three friends realized that he had not, in fact, joined the party of Taraki, they each urged upon him their own literature and implored him to meet with their comrades, who would explain their course of conduct to him in detail. Although Gulab agreed to take a look at their material, he had to prepare for his examinations and did not get around to reading it until

the next year. But the discussion in the room continued, and while Gulab listened, each of the three boys stuck to his position and attacked that of the others.

One day, just before the beginning of the summer vacation, Gulab's brother Sur Gul, who was attending the military academy and whom Gulab now saw only occasionally, came to his room in great excitement. He had been granted a scholarship to pursue his studies in the Soviet Union and would be leaving in six months. Training was provided by the USSR, the only country offering military aid to Afghanistan. The brothers rushed to the bus station—by now buses were running to Khost—and told a relative who was a bus driver to inform the family of Sur Gul's good fortune. A week later Gulab and Sur Gul left for home.

The family had changed during their absence. Gulab's father and elder brother were now involved in smuggling Pakistani cloth to different provinces in Afghanistan and in taking wood from Paktia Province into Pakistan. The father was also negotiating about becoming the agent of a company that imported spare parts for trucks to be smuggled into Pakistan. The family, with a group of friends, had bought some camels for transporting the goods across the border. They had also invested in a minitruck, and Gulab's youngest brother, who had not been sent to school, was transporting people and goods between Khost and the surrounding villages. The family members were wearing better clothes and eating more meat and rice than during Gulab's childhood.

Upon the boys' arrival, the topic of conversation became Sur Gul's impending departure and the responsibilities of the family. Although everybody had heard that the Soviet Union was an atheistic country, the father and elder brother were not particularly worried by this and were happy that Sur Gul had been granted the scholarship. An officer who was related to a business associate had told Gulab's father that recipients of these scholarships advanced very rapidly in their careers and were bound to be entrusted with important governmental posts. Obviously, all the family would gain from his influence.

The discussion turned to the mar-

riage of the two boys. As Gulab was older, he was expected to marry first. The plans had been that Gulab's marriage would take place in a year and Sur Gul's in three years. But Sur Gul's imminent departure changed the whole picture. The family could not meet the expense of two marriages on such short notice and yet did not know how to avoid hurting Gulab's feelings and violating the custom. Sensing the dilemma, Gulab came forward and said there was no need for him to marry at the moment; that he would go and explain the problem to his future in-laws. The father and the elder brother agreed and advised Gulab that when he paid his visit, he should take a sheep and some special presents. Without asking Sur Gul, it was decided that his wedding would take place in a month.

On the eve of the occasion, Gulab's father, his four sons, and some of the elders of the village drove to the bride's village and gave her father the last installment of the bride-price. Half of the money had already been given at the time of the engagement. The total sum amounted to fifty thousand afghanis—the price of one acre of irrigated land—and the family spent another ten thousand on the marriage ceremony itself. The teen-age bride was brought to Sur Gul's village, and during his five years in the Soviet Union, she stayed with his family.

Meanwhile, Gulab gained the confidence of his future mother-in-law, and several times she allowed him to visit his fiancée alone. Gulab found her quite pleasant and was fairly happy with what fate had brought him. He was so busy during all these months that he completely forgot about the literature that his roommates had given him. He saw the books again as he was preparing his bag just before leaving for Kabul.

The political climate of Kabul was as intense as ever, and Gulab soon found himself in the midst of conflicting demands. There were frequent demonstrations, speeches every day in the special corner of the campus, and intense discussions in the dormitory on the merits and shortcomings of various parties. Professors took sides more or less openly and actively tried to build a loyal following among the students. There were allegations that grades reflected the political beliefs of the students more than their competence. There were also rumors that some of the professors took bribes, and that most of the rich students were passing without studying. There was even talk that some members of the faculty took advantage of female students. Everybody was full of accusations, and Gulab did not know whom to believe.

As he slowly read over the material that he was given, one question increasingly bothered him. What did all this have to do with Afghanistan? He read the Chinese attacks on the Soviet Union and those of the latter on the former. He read fragments of a piece on how out of ten hours of work the workers were given wages for only five, but there were very few industrial workers in the country. Even the literature of the Muslim group dealt with Syria and Egypt. Gulab spent most of the year considering the merits of the pieces he was reading and preparing for his exam.

From time to time, his father and two brothers from the village would visit him on their way to other provinces in Afghanistan. The father even spoke of buying some land in northern Afghanistan. Gulab's involvement in the family economy was minimal; he was never asked his opinion and kept his thoughts to himself. But even in his own mind he did not know how to react to the relative expansion of his family's resources.

When Gulab returned for his vacation, plans for his wedding were under way and he was married. By the time he left, his wife was expecting a baby. Gulab, of course, had no income of his own, and all the expenses of his wedding and the maintenance of his wife were paid by the family. He took advantage of every major holiday to visit home, but as the trip took two days each way, he could not make it as often as he wished.

By Gulab's third year of studies, things at the university were in turmoil. Demands for establishing a student council led to a full-scale student strike, and the government stopped supplying food to the dorms and asked the students to leave. Although the university was officially closed for some time, committees of students and faculty met regularly and became even firmer in their demands. Students raised funds from inside the country, and even Afghan students from abroad sent money to provide food for the university. It was during this strike that Gulab became known as a sympathizer of Taraki, although he had not officially joined his party. One day he was taken to Taraki's house, which was located only a couple of miles from the campus. Taraki was a plump man with a cleanshaven head. In his humble manner, he told the group that their demands were legitimate and that history would prove them right.

Gulab was becoming fairly active in the strike when he received a message that his father was seriously ill. He reached home just in time to witness his father's last words, asking his sons to remain united. With the death of his father, the authority in the house passed over to the elder brother. Since harvesttime was approaching and the family had been deprived of an active member, the elder brother asked Gulab to oversee the management of the house. Gulab stayed the summer until the university reopened. During this time his wife gave birth, and he was the father of a son.

Back for his final year at the university, he continued his political activity, which now included trying to recruit others to his beliefs. He was told by members of Taraki's party to make use of his knowledge of local conditions to attract the sympathies of students from the region of Khost. Although some joined, others were quitting. The membership of the various groups was not stable, and there was much crossing over. Gulab himself did not feel particularly bound and still did not join Taraki's party officially. There were more strikes, more protests. All of the city was gripped by the debates in parliament on the question of languages. A proposal for turning Pashtu into an official language was being considered, but for months the quorum was not met. There was also pending a treaty with Iran on the division of the waters of the Helmand River, which had become an issue in the whole country and was portrayed as an act of national

*Because many rural areas lack facilities, classes are often held outdoors. Although compulsory, primary education actually reaches only a small fraction of the population. Fewer girls than boys attend classes, which usually are segregated by sex. The national literacy rate has been estimated to be between 5 and 13 percent.*

Eve Arnold, Magnum

treason by all the opposition parties. Just as Gulab was preparing for his final examinations in the university came the coup of 1973.

Gen. Mohammad Daud, cousin and brother-in-law of the king, and prime minister from 1953 to 1962, overthrew the monarchy and declared the Republic. A large number of the posts in the cabinet were given to junior officers, who according to rumors were sympathetic to the parties on the Left. Yet, open political life in the country came to an end, although it continued underground.

Gulab received his B.A. in chemistry and was assigned to teach high school in the valley of Aryoub in Paktia Province. Aryoub was not very far from Khost, but as it was not on the road between Kabul and Khost, Gulab had never been there. As he rode on the back of a truck toward Aryoub, he was amazed by the beauty of the forest that unrolled in front of his eyes. Unlike the semibarren valleys that surrounded Khost, the mountains were all densely covered with trees. To his dismay, he learned that even from here the wood was increasingly taken to Pakistan. The only government-owned forest was located near the border, and only there did some reforestation take place.

Gulab did not expect the school where he was to teach to be built like the one in Kabul, but he was not prepared for what he saw. The high school, serving about six hundred students, was an old mud house, and most of the classes were held in the open air. Whenever it rained, classes had to be canceled. Next to the school was an unfinished two-story concrete structure; Gulab was told that this was to be the new school, but that contractors and government officials had stolen from the allotted budget leaving it uncompleted. The minister of public works of the new regime had come to the valley, but despite the petition he was presented with by the teachers, the only outcome of his visit was a report in the national newspapers stating that he had been satisfied with the 95 percent completion of the work.

Although all of Gulab's teaching of chemistry was confined to illustrations on the blackboard, he found the students attentive. Only he and the principal, who had a B.A. in literature, were graduates of the university. The other ten teachers had anywhere from six years of schooling to specialized training in teachers' institutes. Despite the seeming geographical isolation of the place, currents of ideas from the rest of the country were very much present. Students quickly started asking Gulab about the political movements in Kabul, and he found out that the teachers had very definite commitments.

Whereas students and teachers were divided along lines similar to those found in Kabul, there were also movements among the peasantry aimed at the revitalization of Islam. A number of theology students, trained in schools in Pakistan, were coming back and trying to teach the peasants what "true" Islam was all about. Gulab also heard of the emergence in a neighboring valley of a soldier as a holy figure; in six months the man had a major following. When the more orthodox mullahs challenged him to a debate, his lack of knowledge of Islamic sources was exposed and he was forced to leave.

While in Aryoub, Gulab sent the major part of his salary home. His wife and child were not with him, and he found his assignment cumbersome. Two years went by. Finally, through some friends and relatives, he secured a contact in the Ministry of Education and managed to be transferred to Khost.

The town had changed considerably. There was a German-operated hospital, as well as a center for reforestation. Shops built of concrete were replacing the old mud structures, and buses and taxis left almost every hour for Kabul. Half of the road to Kabul had been paved; this section could be traversed in about two hours, while the unpaved portion required from four to five hours. Students and teachers were politically active, and the deputy-governor, who had had no formal education himself, kept a wary eye on their activities.

Gulab's elder brother had visited Mecca and was now known as Haji. He had expanded his operations and had even bought a house in Khost where all the male members of the family stayed when they had to remain in town. The youngest brother had also married. Sur Gul was back in Afghanistan and had a post in the armored division in Kabul, but he did not have a house of his own in the city and his wife had to stay with the rest of the family in the village. Every other week he went to see her and his daughter. Gulab too had a daughter now. Although Sur Gul did not share his thoughts with the other members of the family, he confided to Gulab that he had secretly joined Taraki's party and that conditions in the country were coming to a head-on collision. Dissatisfaction with Daud was growing because officers in the regime were being fired, and the regime was drawing closer to Iran.

When one day in April 1978 Gulab heard on the radio that, as a result of their demonstrations in Kabul, Taraki and some other members of the party were arrested, his thoughts went to the safety of his brother. Two days later, however, Daud was killed while resisting a coup, and Taraki became president, prime minister, and chairman of the revolutionary council. Two of Gulab's professors were appointed to the cabinet, as well as some friends of Sur Gul from the armored division. Gulab soon learned that Sur Gul, having played an important role in the coup, had been appointed garrison commander fulfilling the duties of a general. Because Sur Gul was now too busy to leave Kabul, he asked that his wife and daughter be sent to join him. He had been given an apartment and could provide for them. When Gulab took Sur Gul's family to Kabul, he was asked to join Taraki's party and was told that, if he wished, his transfer to another ministry in Kabul could be easily arranged. He answered that he would join the party but preferred to stay in Khost for a while.

Most of the people in the country were stunned by the takeover by Taraki's party and could not really believe it. Many were happy that the old regime had come to an end, and people in Khost were pleased that Taraki was giving his official speeches in Pashtu. Neither the king nor Daud had ever done so, although ethnically they were Pashtuns.

But after some months, disturbing news started to emanate from Kabul. There were rumors of mass arrests and torture of people whom Gulab had gotten to know in his years at the university. There were also rumors that Russians were in charge and that, in response to local armed resistance, the government had dropped bombs on villages in the province of Jalalabad. Parties of people arrived from Kabul and crossed the border to Pakistan. Soon, a number of them were crossing back into the Khost region, openly declaring that they were going to fight the government. Religious dignitaries asserted that religion was in danger, and landlords and moneylenders said that the state was going to confiscate all the belongings of the wealthy. Everybody was taking sides, and people seemed hesitant to speak in front of Gulab.

Government officials said that they were not afraid of any party and that whoever opposed them was reactionary and would be punished. They soon showed that they were not talking lightly. One day, people who came from the Aryoub valley brought the news that planes had bombed the neighboring valley. One after the other, reports of bombing came from every corner of the country, including almost every valley of Paktia Province. Business came to a standstill, and few dared go to Kabul.

In the midst of all this uncertainty, Sur Gul sent his family back to the village. He wrote that he could not live with an ignorant rural wife and was going to marry a member of the party from Kabul. This news made Haji and Gulab's youngest brother so furious that they disowned Sur Gul. Haji also announced that he was going to join the opposition and cross the border; the youngest brother said he was going with him.

Gulab, by this time, was under considerable pressure and did not know what to make of the situation. On the one hand he was witnessing considerable suffering; on the other, the radio was every day proclaiming the glories of the revolution and its achievements for the toiling people. But then came another piece of news. Taraki had been removed from office and replaced by his deputy, Hafizullah Amin. Some weeks later, Taraki's death was announced. Then came news of a huge attack by some four hundred tanks on the town of Gardez, a display of muscle by the central government intended to intimidate the rebels. Khost, by that time, was more or less isolated and few dared move out of it. Gulab was still teaching in the high school, but the number of students was decreasing. Whereas previously nobody had ever asked him whether he prayed, now he had to attend the local mosque and pray with the congregation. The people who showed concern were not strangers; they were his in-laws and kinsmen who told him openly that unless he sided with them, they could not guarantee his safety.

Thus, all his life unrolled in front of his eyes in the early chill of a December morning in the mosque of Khost. Gulab realized that he had to make a decision soon. He could join his brother in the capital by becoming a member of the bureaucracy and embracing the ideology of the emerging regime, but he would have to sacrifice his ties to the community where he was born. Or he could ally himself with his other two brothers in rebelling against the central government; in so doing, he would affirm traditional family ties at the risk of becoming an émigré in Pakistan, severed from his homeland. Neither route could promise safety and security, for the future was too uncertain.

Just as the prayer ended, a soldier came running in, shouting that the Russians had taken over the capital and that President Amin had been shot. There was sudden silence, then a great flurry of noise and activity. Gulab knew that there was no more opportunity for postponement. All his life he had been hesitant about making clear-cut decisions; now he could no longer delay. Either choice was going to be painful.

The sounds in the mosque slowly merged and there was a cry of *Allah u-Akbar*—"God is great." Yet as he looked out of the window, Gulab could see the red flag of the regime unfurling with the wind on top of the government building.

*Gulab is one of some thirty thousand teachers in Afghanistan. In a country where the majority of the people are illiterate, teachers have a very important role to play in implementing the social policies of the new regime. Most of the membership of the leftist parties also comes from the ranks of the teachers. All are confronted with more or less the same choice. How they decide will have a significant bearing on the future of the country.*

---

ERRATUM. We regret that two lines were dropped from page 85 of the May book review by Peter Farb. The complete sentence, which begins on page 84, should read: "Their travels began in Mill Grove, Pennsylvania, where Audubon had arrived in 1803, age eighteen, the illegitimate son of a French merchant-slave trader who sent Jean Jacques to the United States to escape conscription into the French army."

## RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired Occasionally, slight editing is required for clarity. Thank you!

# Celestial Events

### by Thomas D. Nicholson

**The Moon** Phases in July and the first half of August are: last-quarter on July 5 and August 3, new moon on July 12 and August 10, first-quarter on July 20, and full moon on July 27. The moon is an evening object from about July 15 through full moon on the 27th and then appears in the morning sky until early August. About August 13, it reappears as an evening crescent. Perigee moon (nearest the earth) is on July 4 and 30; apogee (farthest) is on July 18 and August 15.

**Stars and Planets** Venus, the spectacular evening star of the spring, becomes equally prominent as a morning star this month. Up with the dawn, it is bright and high in the east each morning until daylight fades it. Mars, Jupiter, and Saturn are still putting on a fair show in the evening sky. All three are low in the southwest at dusk, Jupiter lowest and brightest, near the star Regulus. To the left and higher, Saturn first and then Mars are about as bright as Regulus. The three planets appear progressively lower each night through July. The sun moves from the constellation Gemini into Cancer in July and into Leo in early August.

July 5: Earth is at aphelion, farthest from the sun this year, 152,100,000 kilometers (94,500,000 miles) away.

July 6: Venus, now a bright morning star rising in the east before dawn, ends its retrograde movement.

July 9: At dawn this morning, the waning crescent moon is between Aldebaran, to its right, and Venus, to its left. Shortly after 1:30 P.M., EST (you must adjust for your time zone and for daylight-saving time), the moon covers Venus.

July 11: Mercury, in inferior conjunction, becomes a morning star.

July 15: The young crescent moon is between Regulus and Jupiter tonight. Jupiter, the brighter, to the moon's left, is occulted by the moon at about 10:30 P.M., EST, while it is still above the horizon on the West Coast.

July 16: Tonight the moon is between Jupiter (to its right) and Saturn (to its left).

July 17: The moon has now moved between Saturn (to its right) and Mars (to its left).

July 21: Venus is at greatest brilliancy as a morning star.

July 22: Mercury resumes its direct (easterly) motion.

July 27: A penumbral lunar eclipse (causing only a slight darkening of the full moon) occurs before moonrise in North America.

July 28: The Delta Aquarid meteor shower (about 20 per hour) is at maximum this morning. Look from 1:00 A.M. on.

August 6–7: Look for Venus and the moon on both mornings.

August 10: Today's solar eclipse is annular in a path crossing central South America, partial through all South and Central America, southern Florida, southern and southwestern United States, and Hawaii.

August 10–13: These are the best mornings (from 1:00 A.M. on each day) for viewing the Perseid meteor shower, the most reliable, most productive, and easiest to observe of the year.

August 12–15: The moon passes Jupiter, Saturn, and Mars again. Look for it near the planets in the southwest early in the evening.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those you see in the sky. When you turn to face in other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match stars in the sky with those on the lower half of the map. The map represents the evening sky from about 11 to 12 P.M. on July 1; 10 to 11 P.M. on July 15; 9 to 10 P.M. on July 31; and 8 to 9 P.M. on August 15. Only planets and moon phases above the horizon are shown and all times are EST.

# A Captive of Birds

### by Michael Harwood

BIRD STUDENT, by George Miksch Sutton. *University of Texas Press, $15.95; 240 pp., illus.*

I have to admit I'm prejudiced in favor of bird painters. From all the available evidence, their craft is exceedingly difficult to master. Having neither the temperament nor the talent myself, I find what they do nothing short of magic. So I am more than mildly interested when one of them writes about his adventures and what he thinks about life, tells how he got started and how he works.

There are not many bird artists, however, who write prolifically and well. To be sure, Alexander Wilson was a poet who taught himself to draw birds, Aububon overflowed with words, and Roger Tory Peterson has a pleasing narrative style. Such people are few and far between. And George Miksch Sutton is especially remarkable— an academic ornithologist and bird artist who writes lucid, literate scientific papers and is at his best a fine storyteller.

*Bird Student* is a summing-up of the first thirty-seven years of a life that has by now stretched eighty-two years. It began in Bethany, Nebraska, where George Sutton was born, the first child of an itinerant college teacher and his musician wife. Eventually, there were also three younger sisters, one of whom died in childhood. The family had a hard go of it financially. Father couldn't always find teaching work, so he was now and then a substitute preacher and, for a while, a worker in a rubber factory. He had a romantic streak—wrote drama, declaimed Shakespeare and poetry—and he was public-spirited: once he even ran for governor of Nebraska on the Prohibition ticket. Mother gave piano lessons and conducted choruses. The Suttons moved to Minnesota, back to Nebraska, then to Oregon, Illinois, Texas, and West Virginia—all before George Sutton was nineteen.

In keeping with that itinerary, his education was helter-skelter, and he began college classes without receiving a high-school degree. For objecting to the wartime "militarization" of Bethany College—everyone wearing uniforms, lots of close-order drills—he was dismissed in the autumn of 1918, his senior year, and didn't finish his degree work until 1923. By then he was a professional ornithologist, working at the Carnegie Museum of Natural History in Pittsburgh. He had already been on his first museum expedition to Labrador and had been asked to provide the color plates for Thomas D. Burleigh's *Georgia Birds* and for Harold H. Bailey's *Birds of Florida*. In 1923 he went to James Bay and the following year to southern Florida on two more collecting expeditions for the Carnegie Museum.

At twenty-six, Sutton became Pennsylvania State Ornithologist and chief of the Bureau of Research and Information of the Pennsylvania Board of Game Commissioners. (The salary allowed him to carry out a long-standing plan: he bought his parents a permanent home.) The game commissioners loaned him to Carnegie Museum for an expedition one summer, and he went off to the east shore of Hudson

Bay. While there, he decided to quit his job in Pennsylvania and take his Ph.D. in ornithology at Cornell University. Gathering material for the doctorate, he spent a year on Southampton Island at the north end of Hudson Bay. He earned his degree in 1932 and remained at Cornell for many years as curator of the Louis Agassiz Fuertes Memorial Collection of Birds. The book ends in 1935, with Doc Sutton happily writing about the ambience of his life in the university. (Sutton is now George Lynn Cross Research Professor Emeritus of Zoology and curator of birds for the Stovall Museum of Science and History at the University of Oklahoma.)

So in a way this is a success story. There isn't much brag in Sutton's makeup, yet it does seem that from the time he was quite young he was a self-starter. For example, when he decided at age sixteen to take his bird painting seriously, he wrote to Louis Agassiz Fuertes, then the country's premier bird painter, and asked for help. Fuertes invited him for a visit, and to pay his way Sutton took a job on a road gang. Characteristically, he was quickly made a crew chief. All his life others have been appointing or electing him the man in charge of one thing or another.

But the success story is not the reason for the book. Sutton wants to talk about people and places, birds and bird painting, and the setting of a course for a lifetime's work in ornithology.

Many of his childhood memories are about birds—the stuffed pintail duck he proudly hauled around in a little wagon, the dead birds he dissected, his early sketches in hymnal margins of the birds and bird fragments he saw on the ladies' hats in church, the pet Bantam rooster he dropped in water to see if it could swim, the climb up into a tower to watch barn owls, the browsing after birds in the family dictionary, the dead northern harrier he wrapped in a stocking cap and took to school so that he could stow it in his desk and surreptitiously stroke it once in a while.

The possession of birds was vital to him. The "Simon Pures" in the amateur birding fraternity are going to be offended by Sutton's innocent enthusiasm in this regard. He recalls a crucial boyhood incident: Two male western tanagers were battling in midair, they grappled and fell to the ground close to him, and he tossed his cap on them and picked them up, one in each hand. Now the question was, what should he do next?

> I let the tanagers go—but not without qualms of a sort I had never felt. I didn't know what the birds were, and this ignorance hurt. Their lustrous black, white, yellow, and scarlet plumage was the most gorgeous I had ever held in my hands. All that beauty, that exquisite beauty, I wanted to keep, to have for reference, to show people by way of making clear how wonderful birds could be. Here was an opportunity of a lifetime. But what was I to do with them? How could I preserve them? As they flew off, I felt that I had not quite played fair with an important part of myself.

Years later, on a collecting expedition in Labrador, he shot a purple

**"An eminently readable, endlessly fascinating journal."**

sandpiper, a species he hadn't seen before.

As I flexed the stubby legs and stroked the soft, thick plumage, a real thrill went through me. In a very special sense of the word, that most exciting of shorebirds had become mine, really mine, at last.

That was not the thrill of a trophy hunter. Sutton suffered great remorse after he botched an attempt to kill a polar bear with a shotgun—something he had tried on an impulse, thinking to make his mark among the Eskimos he was with. He tells us he decided to relate the story here "in hopes that other young men, eager to prove their mettle or win renown, will not make the same sad mistake." So for Sutton that was an aberration. The thrill of the bird in the hand had to do with something else—the physical and mystical experience of knowing a bird, the possession of that by which one is himself possessed.

The thrill Sutton felt must be connected to his impulse to draw and paint birds. Perhaps depicting something is another way of possessing it. Unfortunately, Sutton doesn't say what he thinks about that. The only passage in which he touches on why anyone would want to depict a scene or a creature is brief and unsatisfactory. His conclusion is that all art flows from "the desire to tell, the need to be on record, the will to communicate," and that doesn't get at the choice of subjects or the choice of medium.

*Bird Student* is occasionally irritating because of such incompleteness. Sutton tends to skip from anecdote to anecdote to philosophy to narrative to anecdote without joining them where they need joining or developing them into meaty units. This works well for him when he is writing about something that has its own built-in coherence, such as a long expedition. He has a talent for the neat, quick description of an event. But when he is covering ground between expeditions and adventures, the book becomes choppy.

This stylistic weakness is aggravated by his evident use of his autobiography to acknowledge his debt to a number of friends by mentioning their names. They appear in their allotted paragraphs—perhaps alone, perhaps not; the reader learns little or nothing about them, and they are never heard from again. Sutton also critiques some of his artistic efforts, a baffling exercise for the reader who doesn't happen to have the particular works at hand. Sutton would have benefited—as Lord knows we all can—from some good editing. Furthermore, readers familiar with earlier Sutton books—and there have been a good many—will be distracted by the frequent juxtaposition of stories they already know and those that are unfamiliar.

But these cavils aside, the book has much to offer, especially to those who haven't read any Sutton yet. As he shows, professional fieldwork can involve enormous amounts of effort, risk, and expense. A museum mounts an expedition into some remote part of the world for the sake of filling a small but important gap in a collection or to gather specimens for a particular display. Often the weather is contrary, vital equipment breaks or is lost or the need for it has not been anticipated, the birds aren't where they were expected, and the expedition achieves only a small fraction of its nominal goals. Nevertheless, a good deal may be accomplished that wasn't part of the plan—birds found, data collected, and descriptions written up. Ingenuity and adaptability are essential parts of a good field ornithologist's makeup.

One also becomes used to working under primitive conditions. A board nailed to a tree root becomes a skinning table. So does the top of a wooden chest in a schooner's hold, where the naturalist runs the risk of losing a favorite scalpel in the ballast of stones. And in the field, an ornithologist of Sutton's stripe routinely takes chances with his life because so many birds nest in high places. Sutton was a good climber, but on one occasion early in his career a rock pulled loose and dropped him off a cliff; he was lucky to escape with a few broken bones.

There are some good tales here. And a picture of the man emerges—self-effacing, generous, at times plagued by spiritual questions, not altogether sure of himself, but *very* determined and always caught and held by birds. Ornithology and bird painting for Doc Sutton seem to have been from the start not just a life's work but as central to his being as breathing.

*Michael Harwood, who has written several books on birds, is coauthor with his wife, Mary Durant, of* On the Road with John James Audubon *(Dodd, Mead and Co.).*

# Telescope in Space

*An orbiting observatory is the newest apparatus at the service of astrophysicists*

**by Stephen P. Maran**

Astronomers scanning the sky from comfortable swivel chairs far removed from their customary telescopes are making revolutionary studies of stars and gas in our own and other galaxies. This seeming impossibility is made feasible by means of a telescope aboard an observatory spacecraft hovering over the Atlantic Ocean about 22,000 miles above the surface of the earth. This eighteen-inch telescope is equipped with two spectographs—instruments for photographing a spectrum—hooked up to computer display screens at two viewing centers, one in Greenbelt, Maryland, and the other outside Madrid, Spain. The spacecraft is operated by ground controllers in Greenbelt.

The NASA satellite carrying the telescope is called the IUE, for International Ultraviolet Explorer. It is in synchronous orbit, which means that it remains over the same region of the globe at all times, making an orbit once every twenty-four hours and thus keeping up as the earth below turns once on its axis.

The IUE has great operational flexibility. Ground controllers do not depend on occasional passes over far-flung tracking stations to get data from the IUE or to send it new commands. Instead, since it hovers nearly in place, the satellite is always in contact with the Greenbelt facility. When an observing astronomer requests that IUE point at a particular place in the sky, he or she waits until it does so and then sees the view through the satellite telescope on a computer console and a large, wall-mounted display screen. The star of interest can be readily identified and new commands to adjust the pointing of the telescope can be quickly sent if necessary.

The telescope beams the star's image into the entrance hole of a spectrograph. There, the light is spread out into a spectrum and focused onto an electronic image tube, which senses the dim ultraviolet light on its front end and produces an accurate duplicate image in glowing blue at its back. A television camera in the satellite scans the blue picture, makes a time exposure, and then produces an electronic signal that is telemetered to earth, run through computers, displayed on the screens, and recorded for posterity on magnetic tape. There is more to the process than that, but this should provide the general idea.

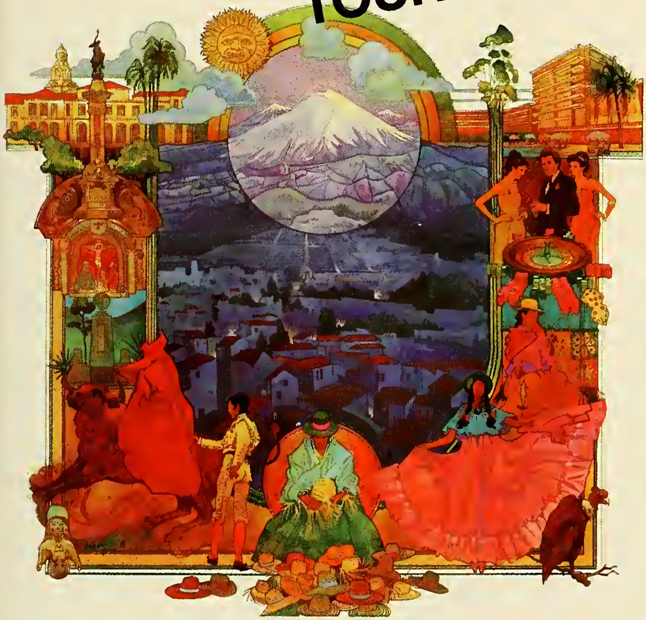
IUE is an astronomy milestone because it allows us to observe the ultraviolet light of much fainter and more distant objects than was possible with earlier satellites. Because ultraviolet light is absorbed by the earth's atmosphere, it must be observed from space. Hot stars are bright in the ultraviolet, while cool stars generally are dim in that part of the spectrum; hence, IUE is ideal for locating and studying hot objects in the cosmos. In addition, the thin interstellar gas can be investigated through its telltale "signature," a pattern of dark lines in the ultraviolet spectra of hot stars located beyond the gas cloud that is under study. The lines are caused by the gas, the stars simply acting as background lamps for the astronomer's convenience.

The observer sees the spectrum displayed shortly after IUE finishes an exposure and while the telescope is still pointing where the picture was taken. Thus, there is time to decide whether the exposure was adequate or needs to be repeated, and to see whether there is anything unanticipated in the spectrum (as there often is) that warrants a change in the observing directions. In other words, working with IUE is like using an ordinary mountaintop telescope, but one that the astronomer cannot touch.

This flexibility is in marked contrast to the limitations of earlier astronomy satellites. Failure to make the right estimates of exposure times or to choose the right wavelengths for observation in the rigidly preplanned observing schedules sometimes resulted in measurements that were not as useful as they might have been.

The "International" in IUE acknowledges that the satellite is a three-way undertaking by NASA, the European Space Agency, and the Science Research Council of the United Kingdom. Albert Boggess, a pioneer space astronomer at the Goddard Space Flight Center in Greenbelt, Maryland, is in overall charge of the satellite. For two eight-hour shifts a day, the observatory is used by American astronomers, who work in a basement room at the Goddard Center. During the other eight hours, the Europeans have their turn at a corresponding fa-

ESCAPADE
ECUATORIANA
TOURS TO SOUTH AMERICA



The wonders and beauty of all the Americas are yours.

Come to our Andes. Come to our Amazon. Come to our America. We've found the most exciting ways through our mysterious jungles, soaring mountains and fabulous cities. We know where nature is perfectly preserved. And we can show you the most relaxing beaches and exciting nightlife. And hotels and restaurants that are always superb. All through Ecuador. And all through South America.

Let our Escapade Ecuatoriana tours show you our America:

1. **Ecuador Siempre.** Guayaquil, Cuenca, Quito, Otavalo. 10 days to really get to know Ecuador.
2. **Project Galapagos.** Quito, Galapagos, Otavalo, Cuenca. 15 days in the wilds and wonders.
3. **Jewels of South America.** Quito, Bogotá, Medellin, Cartagena. 12 days in the most beautiful South American cities.
4. **Ecuador & Peru Combo.** Quito, Lima, Cuzco option. 10 days to see two uniquely beautiful countries.

We can help you select just the right South American Escapade Ecuatoriana tour. For expert advice, please see your Travel Agent.

**Ecuatoriana Vacation Center** NH 780
**Suite 1760, One Biscayne Tower**
**Two Biscayne Boulevard, Miami, FLA 33131**
Escapade Ecuatoriana tours sound like the perfect way to see all of South America. Tell me more.

**Prides of New Zealand...**

Certain countries are synonymous with product excellence. Timepieces from Switzerland, wine from France and caviar from Russia are unquestionably the finest produced in the world. So it is with sheepskin products from New Zealand.

Seldom, if ever, could one find the pride and perfection of New Zealand's manufacture without travelling halfway around the world. Monarch Trading Co. of N.Z. has changed all that.

Browse through our latest full color catalog featuring the finest lambswool rugs in your choice of size and color with virgin pile so deep you can bury your hand, custom auto and aircraft seat covers that keep you cool in summer and warm in winter, sweaters, jackets and slippers of unbelievably soft fleece to luxuriate in...including products never before offered in the U.S.

The prides of New Zealand are shipped duty paid from Honolulu within 48 hours of receipt of your order to you or your gift list with your absolute satisfaction guaranteed. For the latest full color catalog, send your name, address and $3. today to help defray postage and handling. A $10. *Redemption Certificate* will be included.

Available exclusively by mail

cility near Madrid. The setup at Goddard is much like that at a conventional observatory, with star catalogs, sky atlases, and even a microwave oven to warm up midnight snacks.

IUE's ability to discriminate hot objects from cool ones has led to several important findings. One of the latest is the discovery that two well-known cepheid variable stars actually are binary systems. A cepheid is a yellow giant star that pulsates, making its brightness increase and decrease in cyclic fashion. Cepheids are very bright stars and have been intensively studied.

Usually you can tell if a star is a binary by looking for moving lines in its spectrum that shift back and forth gradually as the members of the binary system go around their orbits. The shifting is due to the Doppler effect. If one of the two stars of a binary is much brighter than the other, you find only one set of lines in the spectrum, since the light of the fainter star is lost in the glare of the brighter one. Nevertheless, you can still tell you are dealing with a binary star because the single set of lines does shift back and forth.

In a cepheid's spectrum, only one set of lines is found. These lines also shift back and forth, but that is because the star is pulsating and the Doppler effect makes them shift as the star's surface pulses in and out. That effect masks any possible shifts due to orbital motion. However, astronomers from the Naval Research Laboratory in Washington, D.C., found a way to identify binary systems among cepheid variable stars. In two of the half dozen cepheids that they studied with the IUE, they found excess ultraviolet light beyond that expected from a yellow star. Further, the ultraviolet spectra had the wrong "slopes," meaning that the way in which the ultraviolet brightness changed with wavelength did not correspond to the expected circumstance for a yellow star.

In the case of the cepheid Eta Aquilae, for example, the amount and slope of the excess ultraviolet light correspond to what we would receive from an ordinary white star, such as Sirius or Vega, if it were placed at the distance of the cepheid. One might argue that excess ultraviolet radiation could be produced by some unusual means in a complex, pulsating star, so that it is unnecessary to postulate the existence of a companion star. But there is a fatal objection to this argument: Eta Aquilae gets noticeably brighter and fainter as it pulsates rhythmically once a week. No such changes were found in the ultraviolet light; hence a companion, nonvariable white star must be present. Much smaller than the cepheid, the white star is lost in the visible spectrum where the cepheid shines so brightly, but since the white star is much hotter, it dominates the ultraviolet radiation from the system.

One of the most interesting discoveries made since IUE was launched in January 1978 was the observation of intense blue cores in globular clusters. The latter are spherical aggregations of hundreds of thousands to millions of closely packed stars (see "Stars by the Cluster," *Natural History*, October 1976). As observed with ground-based telescopes, the star images seem to blend together at the center of a globular cluster, so that individual stars cannot be discerned. Further, the cluster light is dominated by the glow of numerous red giants.

Six globular clusters were examined with IUE by a team of scientists led by Andrea Dupree, a noted astronomer at the Center for Astrophysics in Cambridge, Massachusetts. To appreciate what the team found, you need to know what a spectrum looks like. As shown on an IUE display screen, a spectrum consists of one or more long, straight, diagonal bands. Positions along the length of a band correspond to the wavelengths of ultraviolet light. The width of the band at any point corresponds to the size of the image of the target, measured along a certain axis.

If the target is a single star with a pointlike image, the spectral band will be narrow and of uniform width, but if the target is spatially extended, the width will be greater. If a star cluster were composed of identical stars, its spectrum would be of uniform width, since stars at every place along the image axis would produce light over the same range of the spectrum.

Dupree found, however, that the ultraviolet spectrum of a typical globular cluster, such as M15 in Pegasus, is a tapered band, narrower at the shorter-wavelength end than at the longer-wavelength end. This implies that the shorter ultraviolet wavelength radiation is produced by a group of hot stars that must be concentrated in a small region. In the case of M15, the cluster as a whole is roughly ninety light-years in diameter, but the hot stars are located within a central zone of only one light-year.

The observed short-wavelength radiation can be most readily explained as the product of about twenty luminous blue stars. These are not young blue giant stars of the type found in Orion, for globular clusters are too old to contain such objects. Rather, they must be of a less familiar type, called horizontal branch stars after their position in a technical diagram used for classifying stars.

The difficulty with this explanation is that the theory of globular clusters tells us that a given type of star should not be concentrated more strongly at the center of a cluster than other member stars unless it is a very massive type, and horizontal branch stars are not exceptionally heavy. Dupree's way out of this dilemma was to suggest that the concentrated horizontal branch stars are binary systems. Two stars are heavier than one (with some exceptions, of course), so the binaries would be more strongly concentrated at the cluster center than individual horizontal branch stars.

One of the best examples of the use of IUE to study the interstellar gas is an investigation by two astronomers from the University of Wisconsin in Madison. They adopted bright blue giant stars in the Large and Small Magellanic Clouds, two neighbor galaxies of our own Milky Way, as background lamps to study the gas of the Milky Way at high altitudes above the galactic disk. The IUE spectra revealed that there is indeed a thin gas up there, where there are few if any stars, and that the gas is very hot, perhaps 100,000°C. The gas, called the galactic corona by the Wisconsin astronomers, is not primordial, for it contains atoms of carbon, oxygen, silicon, and other elements that must have been made by nuclear reactions within stars. How did this gas get up there? The best guess is that it comes from the disk of the Milky Way, where it was heated by supernovae explosions and then rose upward like steam. This theory remains to be proved, but the observations are valid. Here again, IUE struck pay dirt, or perhaps I should say "hot stuff."

# A Mummy's Travels

Working in the American Museum of Natural History presents occasional problems. One morning last month, for example, the staff of *Natural History* was greeted by the suffocating odor of mothballs. The cause was soon revealed: the mummies in the mummy storage area, which is adjacent to the offices of *Natural History*, had just received a mothball change. And since only a plasterboard wall that reaches halfway to the ceiling separates the quick and the dead, the fumes easily found their way over the top and down again.

The mummy storage area houses most of the human remains (aside from bones) that have, through the years, become part of the Museum's collection. Stored in black tin boxes are burials and mummy bundles from the Americas, trophy heads wrapped in exquisitely woven textiles, and thirty-odd Egyptian mummy heads loaned by the Metropolitan Museum of Art some fifty years ago. Not everything is hidden away, however. In the center of the storage area rest several exhibit cases from the dismantled South American Hall.

By far the most striking sight in these cases is Copper Man, a South American copper miner killed about A.D. 800 when the tunnel in which he was working collapsed. It is not hard to imagine how he got his name: his skin is stained with dull green copper oxides, except where oozing resins have created the illusion of a shiny, metallic surface. His body is remarkably well preserved, and unlike other naturally mummified bodies, only minimal shrinkage of skin occurred. One can trace the details of his musculature and facial features. His hair is neatly braided, and he wears two strips of coarse cloth as a loin covering.

The complete history of Copper Man has recently been pieced together by Junius B. Bird, curator emeritus in the Department of Anthropology. His research, published by Dumbarton Oaks in a volume on pre-Columbian metallurgy, covers not only the anthropological significance of the mummy but also its discovery and subsequent transit through the fairs, marketplaces, and warehouses of Chile and the United States.

Copper Man was unearthed in 1899 in an ancient, collapsed mine shaft at a small mineral claim in the Atacama Desert of northern Chile. Found with him were four coiled baskets, a rawhide bag, a stone hammer, and a spadelike stone implement. He had probably been removing copper ore in a crawl space, hammering and prying out loose rock from cracks and fissures, when the ceiling shifted, pinning him. His arms are still extended in a working position.

According to a letter found by Bird, the discovery of the mummy precipitated an argument between the American owner of the mine, William Matthews, and the Frenchman who was renting it, a M. Pidot. Pidot argued that because the body assayed at slightly under one percent copper, it was ore, and therefore belonged to him. Matthews replied that Pidot had only rented the mine, not the miners.

After a year of negotiation, they finally arrived at a satisfactory financial arrangement and sold the mummy for $1,000 to Edward Jackson, an American entrepreneur living in Antofagasta, Chile. With characteristic Yankee enterprise, Jackson set it up in his house and charged a fee for viewing it. Presumably business was slow, because he soon entered into a partnership with a fellow Antofagastan, Perez de Arce, who was to take Copper Man on tour to Valparaiso and Santiago.

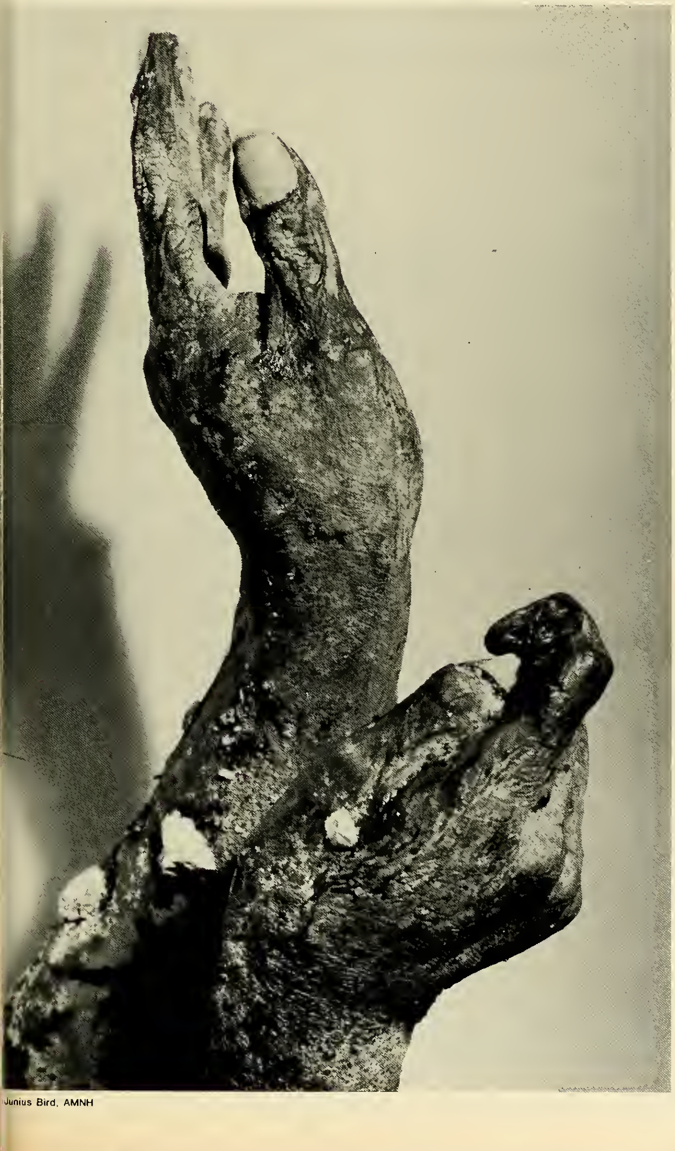
When a few months had passed and no profits were forthcoming from de Arce, Jackson decided the mummy was more trouble than profit and made arrangements to sell it. He soon found out that, unfortunately, getting rid of a mummy was not that easy.

Through the efforts of his brother, Jackson sold the mummy to two businessmen, Srs. Torres and Tornero, for $15,000—$5,000 cash and $10,000 to be paid in three months. Torres and Tornero brought Copper Man to the United States, and after some trouble with the Customs Service displayed it at the Pan-American Exhibition in Buffalo, New York, from May 1 to November 2, 1901. To stir up interest, they printed a pamphlet entitled: *Human Petrification: The Only Specimen in Existence of a Perfectly Preserved Body From a Race Which Is Now Entirely Extinct.*

During the exhibition, excited spectators swarmed into the Chilean building, sometimes climbing over the railings and standing on the furniture to look at the remarkable mummy. At one point, the police temporarily roped off the area after frantic crowds smashed the mummy's glass case.

When the exhibition closed, Torres and Tornero put Copper Man up for sale at an enormous price—fully expecting to become rich men—but there were no takers. They optimistically prolonged their stay in the United States, where they sank deeper and deeper into debt. After a creditor seized the mummy as security, Torres and Tornero returned to Chile thanks to the largess of the Chilean consul.

Because Jackson had never been paid the $10,000 still owed him, the mummy was legally his, but his efforts to regain it were brushed aside by the creditor. In desperation he gave $500 in gold coin and power of attorney to an acquaintance, Raimundo Docekal, who was going to the States



Junius Bird, AMNH

and promised to get the mummy back. After surviving a shipwreck in the Strait of Magellan, Docekal arrived in New York, made a deal with the creditor, canceled the $10,000 debt, sold the mummy, and disappeared.

In a letter to F.D. Aller, Esq., Jackson later wrote: "I looked for him [Docekal] when I was in New York but found it rather too big a place to find him."

After discussing in detail his income and expenses regarding Copper Man, he continued: "I made only $200 on it, and I came to the conclusion that it is a sin to deal in dead men's bodies, and shall not do so again.

"Mummies went up terribly in the market after our find."

The mummy apparently bounced around New York and was finally acquired by the American Museum of Natural History in 1905 through the generosity of J. Pierpont Morgan.

How much Morgan and the Museum paid for the mummy is a mystery. The owner had initially asked for $100,000 but probably got only a fraction of that amount. The proud director of the Museum, Prof. Hermon C. Bumpus, put Copper Man on display almost immediately.

In 1953, two scientists drilled out cores from the body for study, and discovered that the copper oxides had only permeated the skin and were not

*The hands of Copper Man, still extended in a working position, show the remarkable preservation of the 1,200-year-old mummy. The prehistoric South American copper miner lost his little finger (and little toe) to souvenir hunters at the time of his discovery in 1899.*

present in the inner tissues. They also confirmed that the mineral compounds in the surrounding earth had created a sterile environment for the body, preventing bacterial decay.

Junius Bird theorizes that the blood forced into the extremities of the miner's body when he was pinned by the rock probably resulted in the mummy's lifelike preservation. If the skin dried and hardened while distended, the normal shrinkage that takes place during mummification would not have occurred. Bird notes that the Atacama Desert is one of the world's driest regions, an environment where a body could have desiccated this rapidly.

Copper Man remained on display until 1967, when his case was moved into the mummy storage area.

There is some debate in the Anthropology Department over whether the Museum should exhibit Copper Man again. Some curators feel it is improper to display human remains for popular viewing. Bird, however, disagrees. He feels that, as the Americas' only prehistoric miner found with his tools, the mummy would be an important part of the planned hall of South American peoples. "Mining," he says,

> has always been a hazardous occupation. This poor fellow was killed while working with the most primitive of tools under extremely difficult conditions. I feel that if he had anything to say about it he would prefer that people see him as he is so they may better understand what was involved in the making of tools, weapons, ornaments, and other metal products before Europeans came to the Americas.

But at least until the South American hall is built, Copper Man will remain in the gloom of the storage room, being disturbed only when it is time for a change of mothballs.

*Douglas J. Preston*

### Discovery Tours

The Museum is offering members and friends a chance to discover the wildlife of East Africa on safari with Richard G. Van Gelder, curator of mammals. Participants will explore the major game reserves of Kenya and Tanzania, including Nairobi National Game Park, Mount Kenya, Ngorongoro Crater, Serengeti National Park, and Lake Manyara National Park. There will be a brief mid-safari rest in the Seychelles. The first East African safari, scheduled for February of 1981, is booked; however, a second safari in late February still has space available. For more information, write to Discovery Tours at the Museum.

### Tibetan Music

The Society of Myth and Tradition, publishers of *Parabola* magazine, and the Museum's Department of Education are presenting an evening of Tibetan music in the Auditorium on Wednesday, July 2, at 7:00 P.M. Three musicians will sing, chant, and play Tibetan music on drums and trumpets, and Ernest McClain, professor of music at Brooklyn College; Huston Smith, professor of religion and philosophy at Syracuse; and Lobsang Lhalungpa, translator of Tibetan texts, will discuss the music and its relation to Tibetan Buddhism. The program is free to all Museum visitors.

### African-American Summer Festival

On Friday, July 18, and Saturday, July 19, the Museum is planning a series of events focusing on the culture, and traditions of African-Americans, including live music and dance performances.

*Films for Kids.* Friday from 11:00 A.M. to 3:00 P.M., and Saturday from noon noon until 4:00 P.M., a series of short films for children will be shown in the Auditorium. Highlights include *The Lion Game,* Bushman children playing; *A Story, A Story,* an animated African tale about a spider; and *Desert Caravan,* the life of a nomad boy of the Sahara.

*Films for Adults.* Running concurrently with *Films for Kids* will be a series of films in the People Center. Among them are *I Shall Moulder Before I Shall Be Taken,* about the Djukas of Surinam, South America, who escaped from slavery; *Bitter Melons,* in which an old blind Bushman celebrates his hunting-gathering life in song; and *Men of Bronze,* about the first black regiment of World War One.

*Bamiki Dance Group.* On Friday at 1:00 P.M. at the 77th Street entrance, young performers from Lincoln Square Neighborhood Center's Bamiki dance group will present *The Bird with the Most Beautiful Song,* a program of African mime and dance.

*Ladji Camara African Dance and Music Ensemble.* On Saturday at 1:00 P.M. at the 77th Street entrance, this acclaimed ensemble will perform traditional African dances and songs.

*No Maps on My Taps.* On Saturday at 2:00 P.M. in the Education Hall, this 1979 film about three old-time Harlem tap dancers will be shown.

*Tap Dance Demonstration.* Eleanor Harris, noted choreographer and dance teacher, will demonstrate tap dancing and invite audience participation on Saturday at 3:00 P.M. in the Education Hall.

For more information, write to the Museum's Department of Education.

Offers a Home Study Course in Bird Biology
Inquire: NH, 159 Sapsucker Woods Road, Ithaca, NY 14850

**Trilobites** (p. 46)

Details of the distribution of calmoniids, including the influence of plate tectonics, can be found in the scientific report "Biogeography of Silurian and Devonian Trilobites of the Malvinokaffric Realm," by N. Eldredge and A.R. Ormiston, in *Historical Biogeography, Plate Tectonics, and the Changing Environment*, edited by J. Gray and A. Boucot (Corvallis: Oregon State University Press, 1979). A well-illustrated introductory text on historical geology, *Evolution of the Earth*, third edition, by R. H. Dott, Jr., and R. L. Batten (New York: McGraw-Hill Book Co., 1980), discusses continental drift and the basic features of evolutionary theories. A multiauthored symposium, *Vicariance Biogeography: Congruence of Earth History with Plant and Animal Distributions*, edited by G. J. Nelson and D. E. Rosen (New York: Columbia University Press, forthcoming), offers a balanced view of contemporary method and theory in biogeography. "A Trilobite Odyssey," an earlier article by N. Eldredge and M.J. Eldredge, can be found in the December 1972 *Natural History*.

**Salmon** (p. 52)

A. Netboy's latest book, *Salmon: The World's Most Harassed Fish* (London: André Deutsch, 1980), discusses the most recent information on the life histories and survival problems of Atlantic and Pacific salmon. An earlier book by Netboy, *The Salmon: Their Fight for Survival* (Boston: Houghton Mifflin, 1974), also provides background to "Those Salmon Keep Butting Those Dams" and should be available in most libraries. *Salmon Fishers of the Columbia*, by C. L. Smith (Corvallis: Oregon State University Press, 1979), is an illustrated popular history of the salmon-canning industry. In *Pacific Troller: Life on the Northwest Fishing Grounds* (Anchorage: Alaska Northwest Publishing Co., 1978), F. E. Caldwell gives a firsthand description of life on a troller.

**Afghanistan** (p. 64)

V. Gregorian's *The Emergence of Modern Afghanistan: Politics of Reform and Modernization 1880–1946* (Stanford: Stanford University Press, 1969) is a modern history with special emphasis on socioeconomic development and the policies that determine it. *Afghanistan*, by L. Dupree (Princeton: Princeton University Press, 1973), takes a more anthropological approach and discusses the processes involved in changing from a tribal society to a nation-state. The social, cultural, economic, and political trends in contemporary Afghan society are the subjects of *Afghanistan in the 1970s*, edited by L. Dupree and L. Albert (New York: Praeger Publishers, 1974), a collection of essays by Afghans and Americans. Of particular interest are Baqui Yousefzai's "Kabul University Students: A Potential Political Force?" and William Sayres's "Old Trails and New Paths in Education." R. Akhramovich, a leading Soviet expert on Afghanistan, gives the Soviet point of view in *Concerning the Recent Stages in Afghanistan's Social History*, published in Moscow in 1967. An anthropological analysis of two ethnic groups in northern Afghanistan along the Soviet border is presented by M. N. Shabrani, a native of the area, in *The Kirghiz and Wakhi of Afghanistan* (Seattle: University of Washington Press, 1979). M. Slobin writes of his two-year study of the relationship of music and ethnic identity in his *Music in the Culture of Northern Afghanistan* (Tucson: University of Arizona Press, 1976). The ethnographic and trading situation in central Afghanistan is discussed in "Nomad Expansion and Commerce in Central Afghanistan," by K. Ferdinand (*Folk*, vol. 4, 1962, pp. 123–59).

# Stalking the Cultivated Gooseberry

*It takes work to find a gooseberry*
*or even a gooseberry fancier*

**by Raymond Sokolov**

> I am going to turn over a new life and I am going to be a very good girl and be obedient to Isa Keith, here there is plenty of gooseberries which makes my teeth watter.
>
> Marjorie Fleming (1803–1811)

Before her untimely death at the age of eight, the precocious British diarist Marjorie Fleming had already acquired her nation's taste for the tart and hairy fruit of *Ribes grossularia.* For my own part, as a more or less typical American, I did not even try a gooseberry until, as a nominally mature 22-year-old Fulbright student, I sat down to dinner at Wadham College, Oxford, and having picked desultorily at the main course, braised ox heart, fell upon the dessert—gooseberry compote—with a gusto that diminished after the first bite.

The once-green and translucent berries had lost their shimmer in the canning process, but I could still make out the delicate, longitudinal striping on their skins. The actual flavor did not then mightily attract me. Over the years, however, I have put away this childish phobia and ceased to be a gooseberry fool. Now, back in the United States, I have a new problem. Fresh gooseberries are almost as rare as the great auk.

Prepared gooseberry products are easy enough to find in this country. On a recent visit to a specialty store, I turned up two kinds of gooseberry preserves (one English, one from Oregon) and a jar of canned whole gooseberries from Germany. But fresh gooseberries seemed to be only a midsummer's dream until a hot tip from a horticulturally alert friend sent me out to the eastern tip of Long Island and beyond, by ferry over Gardiner's Bay, to Shelter Island.

Stalking the cultivated gooseberry on that seagirt and historic summer mecca was soft work, but I got there just in time. Kathleen Brown, who had been tending her opulent garden on the island for seventeen years, was just packing the last of her belongings and preparing to move to a planned retirement community in southern California.

The berry patch was still in place, however, on a small plot behind a cheerful yellow ex-privy in the middle of a sunlit lawn bordered by a mob of lilies. Tangled branches with long thorns and curly green leaves were tied off in sections to make it easier to pick fruit during the short season that runs, on Shelter Island, from the end of June until late July.

The stand of shrubbery wasn't particularly imposing but for years it provided Mrs. Brown with enough berries for a cash crop. In 1977, her best year, she picked twenty-seven quarts and sold most of them at a local farm stand. You couldn't call it a phenomenal output, but the outsider, knowing how unlikely it is to find such a thing at all, wondered why Mrs. Brown had turned her green thumb in this unusual direction. Was it a case of anglophilia or a yearning for the exotic?

"I didn't know there was such a thing as a gooseberry," she said. "A friend gave me a bush. She had a lot. I layered more every year. Gooseberries are no trouble at all."

In the mild climate of her garden, under her watchful eye, this may be so, but the fact is that the gooseberry has had a hard time of it in this country, even though, in the beginning of British colonization, there was every cultural reason for it to have prospered on American soil.

Apparently, early settlers did try to transplant European gooseberries, but they failed. *Ribes grossularia,* which had been cultivated in northern Europe since as early as the sixteenth century, did not adapt to our climate. Imported shrubs succumbed to a fungus known as gooseberry mildew, which attacked the leaves, twigs, and fruit of the plant, covering it with its weblike mycelium in the spring.

All was not lost, however. In the nineteenth century, a native wild gooseberry turned up in New Hampshire and Vermont. By 1846, Abel Houghton, Jr., of Lynn, Massachusetts, had cultivated it, probably from seed of the plant now called *Ribes hirtellum.* Subsequent hybridization with European strains led to viable cultivars with commercially exploitable fruit, inferior in flavor to the European gooseberries, which can be eaten out of hand, but still a delectable berry for jams and cooked desserts (see recipes).

High hopes for the American gooseberry soured when it transpired that it, like its *Ribes* cousin, the black currant, played host to a virulent fungus, *Cronartium ribicola,* which attacks five-needle pines. In fact, the so-called white-pine blister rust is such a threat to the timber industry that federal and state laws regulate shipment and cultivation of gooseberries and black currants.

Clearly, the white pine has a far more important role in American life than the gooseberry. And in the conflict between the two plants, the gooseberry has lost out. Production figures

W H. Hodge, Peter Arnold

for American gooseberries are hard to come by, but the annual crop is not large. In its statistical tables the U.S. Department of Agriculture lumps gooseberries together with "miscellaneous fruits and berries." The department did publish numbers for frozen gooseberries until 1970, when 540,000 pounds of the fruit were processed, as compared with some 29 million pounds of blackberries and 202 million pounds of strawberries.

It would be unfair to lay the blame for the meager gooseberry harvest entirely at the door of the timber lobby. Fruit growers would, I am sure, have found a way to grow gooseberries safely and in quantity if there had been a strong public demand for them. But the high acidity of domestic gooseberries has undoubtedly played a real part in making them unpopular. A sweet-toothed populace eager for convenience foods will opt for sweeter fruits that can simply be popped into the mouth.

And then there is the matter of the name "gooseberry" itself. It makes the fruit sound funny, especially the way we Americans pronounce the word. In England, they disguise the poultry aspect of their gooseberries with a pronunciation that sounds like "guzbry." When you hear it you don't think of a goose. This is etymologically reasonable, since the term may very well have nothing to do with geese at all. No one knows for sure, but it is not hard to see how "gooseberry" may have evolved from the Dutch *kruisbezie*, the German *Krausbeere*, or the French *groseille*.

Even if gooseberry does have some fanciful connection with geese, the domestic species and hybrids still offer an alternative to more familiar berries for anyone who wants to try a complex and distinguished summer fruit. Some farm stands and fancy fruiterers carry them. And the home gardener can find shrubs for sale at nurseries. I recently saw a small plant for sale in Manhattan at $5.99.

The standard method of propagation is mound layering. After severe pruning, so that the plant has been cut back almost to the ground, heap soil around the bases of the stems, which will send out roots. Then set out the rooted stems and let them develop into new plants.

Mrs. Brown layered her gooseberry patch by cutting into long stems on the bias, painting the cut with a commercial rooting chemical and burying the cut area underground. A brick was placed over each buried piece to hold it in place. She did this at the end of the season and never cut her plants back, thereby probably reducing her overall crop since the heaviest output normally occurs on wood under three years old.

But Mrs. Brown has a green thumb. She knew how to keep gooseberry maintenance to a minimum. In early May, she fed her patch with 5-10-5 fertilizer. She sprayed the bushes with Sevin, one tablespoon per gallon of water, to hold down insect infestation. Then, all she had to do was wait and pick the berries before the birds got to them.

> You pick them when they're half green, with a red blush. When they've turned solid red and started to fall on the ground, it's too late. In the beginning, I waited until they were all red and picked them very carefully. Then I learned that earlier was better. I was so amazed that you could take these green gooseberries and cook them and then see them turn red.

Color will vary among varieties, but the result is the same, plenty of fruit for ten to twenty years, after two or three years of waiting for the patch to take hold. Gooseberries will not do well in hot, dry climates. But these are hardy plants, whose range extends nearly to the Arctic Circle. Many people leave them alone altogether. With any luck, Mrs. Brown's patch will survive and continue to bear fruit, even after she leaves for Chula Vista and abandons her beloved gooseberries to a new, possibly uninterested owner.

### Gooseberry Fool

(Traditional English recipe adapted
from Elizabeth David's *Summer Cooking*)

1 pound hard green gooseberries
10 tablespoons sugar, approximately
½ cup heavy cream, whipped

1. Cook the gooseberries and sugar in a double boiler until the berries are quite soft. There is no need to top and tail the gooseberries.
2. Push the gooseberry mixture through a strainer or run through a food mill. Chill.
3. Stir in the whipped cream. Add more sugar if the fool is too acid. Serve very cold.

Yield: 3–4 servings

### Mary Peacock and Amanda Stinchecum's Illinois Gooseberry Fool

1 quart gooseberries
1¼ cups sugar
5 egg yolks
1 pinch salt
1½ cups scalded milk
1 teaspoon vanilla
1 cup heavy cream, whipped

1. Cook the gooseberries until soft with ¾ cup sugar and ¼ cup water. Mash a bit.
2. Beat the egg yolks lightly together. Then gradually beat in the remaining ½ cup sugar and continue beating until the the mixture lightens in color and forms a ribbon.
3. Beat in the salt, then the scalded milk in a slow stream.
4. Heat the egg mixture over boiling water or over low to moderate heat until it thickens. If some scrambling of the yolks occurs, pour the mixture through a fine strainer.
5. Stir the vanilla into the egg mixture. Cool. You will get a light, pourable custard sauce.
6. Pour the custard sauce (crème anglaise) over the fruit mixture.
7. Top with whipped cream just before serving.

Yield: 4–6 servings

# AMERICA'S MOST POPULAR SPORTS CAR

Ford Mustang's No. 1. And for good reason. It's not just any small car.

Take a look at it. Sleek, stylish, aerodynamic.

Get behind the wheel. Experience its impressive ride and handling.

**23** EPA EST. MPG* **38** EPA EST. HWY* Take a look at its economy. Mustang has the high mileage and low sticker price you need today.

And just look at our standard features—rack and pinion steering, modified MacPherson front suspension, 2.3 liter overhead cam engine, dual halogen headlamps, full instrumentation, and more.

*Estimates for comparison. Your mileage may differ depending on speed, distance and weather. Hwy. mileage and Calif. estimates lower.

**New 5-speed overdrive.**

Get all the excitement of an optional 5-speed overdrive, plus a world of other options—turbo, V-8, Michelin TRX radial tires, forged aluminum wheels . . . even a flip-up open air roof.

With all this going for you, it's no wonder Mustang is America's most popular sports car.

## Six-mode exposure control. System versatility. Newer electronics for wider applications.

SHUTTER PRIORITY AE
PROGRAMMED AE
ELECTRONIC FLASH AE
MANUAL
STOPPED-DOWN AE
APERTURE PRIORITY AE

The incredible Canon A-1. It's on the cutting edge of technology, with state-of-the-art electronics and computerized operation.

Yet, although the way we build it is complex, the way you use it is the ultimate in simplicity. If push-button-easy fine photography is what you're after, the A-1 can give it to you six ways.

1 Shutter-Priority automation: You pick the speed to freeze or blur action or prevent camera shake, the A-1 picks the perfect aperture automatically.

2 Aperture-Priority automation: Select the aperture you want for a soft background or total overall sharpness, the A-1 will give you the speed that's correct.

3 Programmed automation: On the A-1, this unique exposure mode picks both aperture and speed in ideal combinations depending on the light. You don't have to set *anything*.

4 Stopped-Down automation: This mode lets you get automatic exposure with any lens or accessory you can mount on the camera. Great for astrophotography, photomicrography, close-ups.

5 Flash automation: The A-1 has the easiest electronic flash of any camera of its type. With special Canon flash units, your aperture and speed are set automatically. Just mount the flash, turn it on and shoot for perfect exposures every time.

6 For any type of photography that's not already covered, there's manual.

There's more. Digital control and viewfinder display. Versatile control features. Accessories like a rugged motor drive, compact motorized film winder and interchangeable date/data back. Plus forty Canon FD lenses for unsurpassed image quality and scope.

You won't find another camera like it on the face of the earth. Because only Canon has the technology to make it. Luckily, you don't have to go to the ends of the earth to get an A-1. Only as far as your local Canon dealer.

# SONY INTRODUCES A CASSETTE DECK FOR PEOPLE WHO WOULD ONLY CONSIDER REEL-TO-REEL.

Until now the superiority of reel-to-reel tape decks to cassette decks has gone unquestioned.

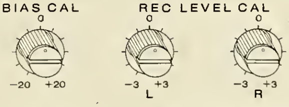
But Sony, renowned for its unique ability to perfect each link in the recording chain—microphones, motors, tape heads, even the tape itself—has just created the TC-K81. A cassette deck so advanced it delivers the kind of crisp, clear, unwavering sound reproduction you would only expect from reel-to-reel.

### HEADS WITHOUT HEADACHES.

Just as in the best open reels, at the heart of the Sony TC-K81 cassette deck are three separate heads. One to erase, one to record and one to play back. This arrangement offers instantaneous "off-the-tape monitoring." Which means you can compare the quality of the recorded music to the quality of the original—while you're recording.

In addition, each head can be optimized for its own specific function.

Of course, fitting three heads into the tiny cassette shell openings, accurately, for years on end, is no small feat. Especially since the slightest alignment error can cause significant high-frequency loss. So to make sure you hear all the sound you're supposed to, Sony has created a major breakthrough in head design with a unique independent suspension system.



This remarkable system allows incredible precision and consistency in head alignment. And just as important, there's no longer the need for you to realign the heads from one tape to the next as in other cassette decks. Equally innovative is that only Sony uses heads that are a combination of Sendust and Ferrite. So you get the advantages of both, without the disadvantages of either.

### TWO FUNCTIONS, TWO MOTORS.

Because tape-speed irregularities can affect your music, the K81 has two separate motors. One takes care of fast forward and rewind, while the other, combined with what we call "Closed-Loop Dual-Capstan Drive," moves the tape with absolute uniformity past the heads. There's no pulling, pushing or tugging.

This division of labor reduces the number of mechanical parts needed in the drive mechanism and virtually eliminates wow and flutter.

### THE LAST WORD IN FINE TUNING.

All tape is not created equal. So the K81 features front-panel bias calibration controls. These allow the K81 to be hand-tailored in order to get the ideal high-frequency response out of each individual tape.

And to insure your recordings are made on a background of silence, free of annoying tape hiss, the K81 incorporates the Dolby® Noise Reduction System. But Sony goes one better with a foolproof record calibration device that insures the Dolby System will always work at its peak effectiveness.

Obviously we could fill pages on the technological advancements in the K81. Like the two 16-segment, LED Peak Program Meters. Or the special "Auto-Space Record Mute" which allows you to blank out commercials and other interruptions.

But you don't have to understand all the circuitry to know what makes the K81 superior.

When it comes to high fidelity there's only one thing you have to know. And that's Sony.

**SONY®**
High Fidelity

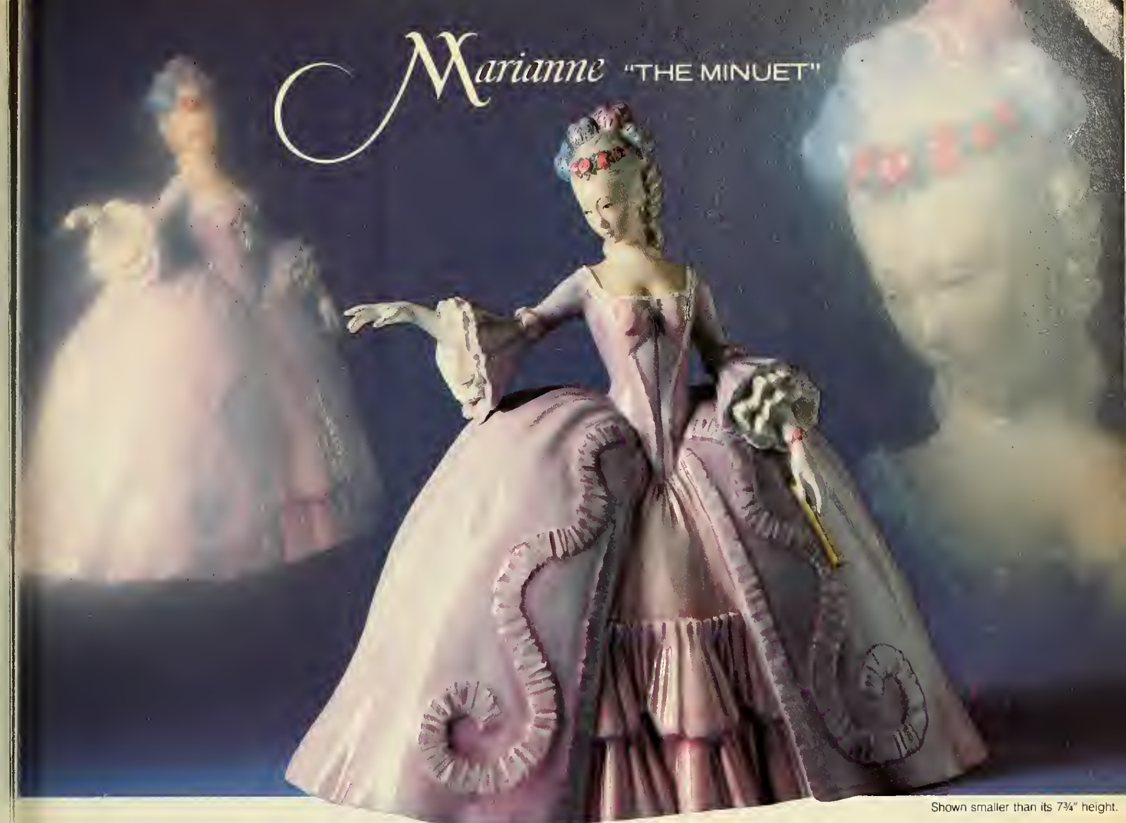
# *Marianne* "THE MINUET"



Shown smaller than its 7¾" height.

The premier figure in *"The Belles of the Ball,"*
an outstanding new collection of hand-painted costume figurines in fine porcelain.
A limited edition issue of The Museum of Costume, Bath, England.

**An original porcelain sculpture of exceptional beauty by a distinguished artist at the very attractive price of $90.**

**Available for a limited time only.**

**Your reservation valid only if mailed by August 31, 1980.**

The figure of an 18th-century woman—beautiful and full of grace. Pausing in mid-step as she dances the favorite dance of the time: the minuet. Clad in a ravishing ball gown of the early 1770s—the kind every woman would love to wear—all ruffles and lace.

The figure? A remarkable work of art in fine porcelain. Elegantly sculptured. Hand-painted in exquisite colors, and glazed with a rich sheen that seems almost to give it a life of its own. Superbly detailed—even down to the fan and tiny pendant earrings picked out in *pure 24 karat gold.*

This is *Marianne—"The Minuet".* Commissioned by The Museum of Costume, Bath, England, from the distinguished costume artist Steven Gregory. To be crafted for the Museum by Franklin Porcelain in Japan—home of some of the world's most gifted and experienced porcelain craftsmen.

In keeping with established collecting tradition, *Marianne* will be available during the issue year of 1980 only. Affording the exclusivity of a limited edition—at a price designed to place the figure within reach of all who love beauty... art... and the romance of the past. Just $90, payable in three installments. *When all valid orders are filled, the original molds and designs will be destroyed, so the work may never be issued again.*

*Marianne* is the first in a new series, "The Belles of the Ball." Owners will be notified of future issues in the series—and may acquire them if they wish. There is no obligation.

Each figure will be crafted to order. To take advantage of this exceptional opportunity, return the reservation form at right to Franklin Porcelain, Franklin Center, Pennsylvania 19091, no later than August 31, 1980.

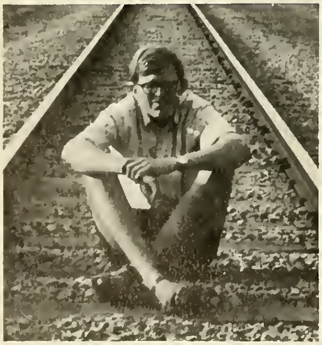
"I am something of a compulsive writer, artist, and photographer," explains **Paul A. Johnsgard**, "lurching from one to another of these activities like a drunken barfly, and usually working on at least three books simultaneously." True to his word, Johnsgard, a professor of zoology at the University of Nebraska, reports that he is at work on a book on the shorebirds of the world, another on the grouse and ptarmigans of the world, and a third on the hummingbirds of North America. Fieldwork associated with the production of these ambitious tomes will cover a goodly chunk of time over the next several years. Somehow, he also finds the opportunity to contribute regularly to *Natural History*.

The Academy of Natural Sciences in Philadelphia, where **Daniel Otte** is an associate curator of entomology, has a huge collection of horned beetles. Otte writes, "It occurred to me that these animals have never been measured as horned mammals have, and that the existence of certain morphological patterns would contribute to the theory of horn evolution." When not measuring the length of beetle horns and pondering their evolution, he pursues research on the behavior, biogeography, and systematics of North American grasshoppers and Australian and Hawaiian crickets. A native of South Africa, Otte also serves as adjunct professor of biology at the University of Pennsylvania and is hard at work on a three-volume handbook on North American grasshoppers.



Cheryl Sonnichsen

Photographer **Carol Beckwith** first went to Kenya in 1974. She bought a 45-day ticket but stayed for eight months. "I was drawn to the Maasai visually and intrigued by their life style," she says. "Here were a people blending in with their environment, who rejected the modern world because they found their traditional ways superior to ours." Only much later did Beckwith recognize that the Maasai faced cultural extinction through the modernization of the Third World. Four years after her initial trip, Beckwith returned to Kenya to work on her book on traditional Maasai culture from which the article in this issue was adapted. A graduate of Goucher College in Maryland, Beckwith spent two summers at the Skowhegan School of Painting and Sculpture in Maine and did graduate work at the School of the Museum of Fine Arts in Boston. Her paintings and photographs have been exhibited in solo and group shows over the past decade.

ESCAPADE ECUATORIANA

TOURS TO SOUTH AMERICA

**The wonders and beauty of all the Americas are yours.**

Come to our Andes. Come to our Amazon. Come to our America. We've found the most exciting ways through our mysterious jungles, soaring mountains and fabulous cities. We know where nature is perfectly preserved. And we can show you the most relaxing beaches and exciting nightlife. And hotels and restaurants that are always superb. All through Ecuador. And all through South America.

Call toll-free 800-327-1337
1-800-432-1372 in Florida only.

**Let our Escapade Ecuatoriana tours show you our America:**

**1. Indian Culture Tours.**
The trail to Machu-Picchu is only one of the paths to Indian and jungle life you can explore.

**2. The Living Amazon.**
The mightiest river in South America reveals its secrets of primitive culture and untamed nature.

**3. Cities of South America.**
Take your pick of the most exciting and beautiful cities in all the Americas.

**4. Galapagos. Islands of natural wonders.**
Visit the enchanted islands where the exotic wildlife sparked Darwin's theories.

We can help you select just the right South American Escapade Ecuatoriana tour. For expert advice, please see your Travel Agent.

ECUATORIANA
the airline of all the Americas

A Maasai from a family of many children, author **Tepilit Ole Saitoti** combines within his person both the traditional and modern worlds. He tended cattle, sheep, and goats until the age of eight, when his father sent him to a government school. After eight years of schooling, he became a traditional warrior and proved himself brave in that role by killing a lion that attacked his father's herd. In 1967, Saitoti joined the Tanzania National Park Service and soon became a ranger and guide. Four years later he was selected to star in *Man of the Serengeti*, a National Geographic Society film. After obtaining a language certificate at the Goethe Institute in Munich, Saitoti flew to Los Angeles to narrate the film. He then toured the American university circuit showing the film. In 1976, he received an honors B.F.A. degree in creative writing from Emerson College in Boston, after which he continued his Western education at the University of Michigan, where he earned a master's degree in environmental studies. Saitoti and Beckwith met initially in Boston at an exhibition of her African paintings.

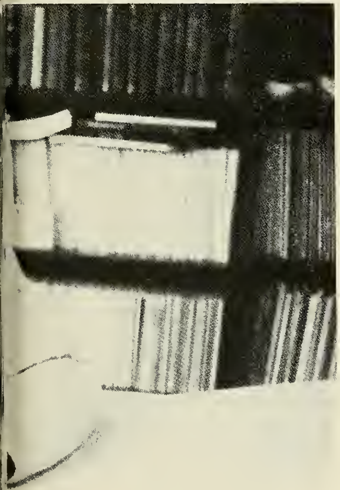
In 1969, **William H. Whyte** helpe draft the "Plan for New York City" a design drawn up for the city's Pla ning Commission. He thought then directly observing "just how the cent city functioned or nonfunctioned The next year, at Hunter College, h conducted a course called "Expe ence of the City." This led to t founding of the Street Life Project an attempt to observe the city sy

As U.S. chairman of the Area on Prevention of Water Pollution of the U.S.-U.S.S.R. Joint Agreement on Environmental Protection, biologist **Wayland R. Swain** has made six trips to the Soviet Union. These overseas visits have enabled Swain, a specialist in the ecosystems of the Great Lakes, to examine at firsthand what he estimates to be about 85 to 90 percent of the surface water in North America and Russia. His interest in freshwater bodies began in 1961 when he was a graduate student at the University of Minnesota and "discovered" large lakes in the literature of the required reading. His 1979 visit to Lake Baikal "fulfilled a nearly twenty-year-old dream," he says.

Although he works at the Environmental Protection Agency, the article in this issue of *Natural History* was written by Swain in his private capacity. No official support or endorsement by the Environmental Protection Agency or any other agency of the federal government is intended or should be inferred.

Earthquakes in the central and eastern United States are the professional concern of research geophysicist **Robert M. Hamilton**. A native of Texas who earned his Ph.D. in California but now lives in and likes the East, Hamilton is chief of the Office of Earthquake Studies of the U.S. Geological Sur-

tematically through time-lapse photography and other kinds of film research, note taking, and hours of observation. Just how city outdoor spaces work or fail to work is described in his book *The Social Life of Small Urban Spaces*, from which this article has been adapted. Mr. Whyte, a former editor of *Fortune* magazine, is the author of *The Organization Man* and *The Last Landscape*.



vey in Reston, Virginia. Research on the cause of earthquakes has taken him on field trips to New Zealand, southern California, Nevada, and Kenya. Projected research projects involve investigating the relation of earthquakes to the deep structure of the earth's crust.

# The Piltdown Conspiracy

*A famous priest apparently was involved in the most spectacular scientific fraud of this century*

**by Stephen Jay Gould**

### Introduction and Background

*Of Conspiracies*

In his great aria "La calunnia," Don Basilio, the music master of Rossini's *Barber of Seville*, graphically describes how evil whispers grow, with appropriate watering, into truly grand and injurious calumnies. For the less conniving among us, the same lesson may be read with opposite intent: in adversity, try to contain. The desire to pin evil deeds upon a single soul acting alone reflects this strategy; conspiracy theories have a terrible tendency to ramify like Basilio's whispers until the runaway solution to "whodunit" becomes "everybodydunit." But conspiracies do occur. Even the pros and pols now doubt that Lee Harvey Oswald acted alone; and everybody did do it on the Orient Express.

The Piltdown case, surely the most famous and spectacular fraud of twentieth-century science, has experienced this tension ever since its exposé in 1953. The semiofficial, contained version holds that Charles Dawson, the lawyer and amateur archeologist who "found" the first specimens, devised and executed the entire plot himself. Since J.S. Weiner's elegant case virtually precludes Dawson's innocence (*The Piltdown Forgery*, Oxford University Press, 1955), conspiracies become the only reasonable refuge for challengers. And proposals for coconspirators abound, ranging from the great anatomist Grafton Elliot Smith to W.J. Sollas, professor of geology at Oxford. I regard these claims as farfetched and devoid of reasonable evidence. But I do believe that a conspiracy existed at Piltdown and that, for once, the most interesting hypothesis is actually true. I believe that a man who later became one of the world's most famous theologians, a cult figure for many years after his death in 1955, knew what Dawson was doing and probably helped in no small way—the French Jesuit priest and paleontologist Pierre Teilhard de Chardin.

*Teilhard and Piltdown*

Teilhard, born in Auvergne (central France) in 1881, belonged to an old, conservative, and prosperous family. Entering the Society of Jesus in 1902, he studied on the English island of Jersey from 1902 to 1905 and then spent three years as a teacher of physics and chemistry at a Jesuit school in Cairo. In 1908, he returned to finish his theological training at the Jesuit seminary of Ore Place in Hastings, providentially located right next to Piltdown on England's southeast coast. Here he stayed for four years, and here he was ordained a priest in 1912. As a theological student, Teilhard was talented enough, but lackadaisical. His passion at Hastings was, as it always had been, natural history. He scoured the countryside for butterflies, birds, and fossils. And, in 1909, he met Charles Dawson at the focus of their common interests—in a stone quarry, hunting for fossils. The two men became good friends and colleagues in pursuit of their interest. Teilhard described Dawson to his parents as "my correspondent in geology."

Dawson claimed that he had recovered the first fragment of Piltdown's skull in 1908, after workmen at a gravel pit told him of a "coconut" (the entire skull) they had unearthed and smashed at the site. Dawson kept poking about, collecting a few more skull pieces and some fragments of other fossil mammals. He did not bring his specimens to Arthur Smith Woodward, keeper of paleontology at the British Museum, until the middle of 1912. Thus, for three years before any professional ever heard of the Piltdown material, Dawson and Teilhard were companions in natural history in the environs of Piltdown.

Smith Woodward was not a secretive man, but he knew the value of what Dawson had brought and the envy it might inspire. He clamped a tight lid upon Dawson's information prior to its publication. He wanted none of Dawson's lay friends at the site, and only one naturalist accompanied Dawson and Smith Woodward in their first joint excavations at Piltdown—Teilhard de Chardin, whom Dawson had described as "quite safe." More specimens came to light during 1912, including the famous jaw with its two molar teeth, artificially filed to simulate human patterns of wear. In December, Smith Woodward published and the controversy began.

The skull fragments, although remarkably thick, could not be distinguished from those of modern humans. The jaw, on the other hand, except for the wear of its teeth, loudly said "chimpanzee" to many experts (in fact, it once belonged to an orangutan). No one smelled fraud, but many professionals felt that parts of two

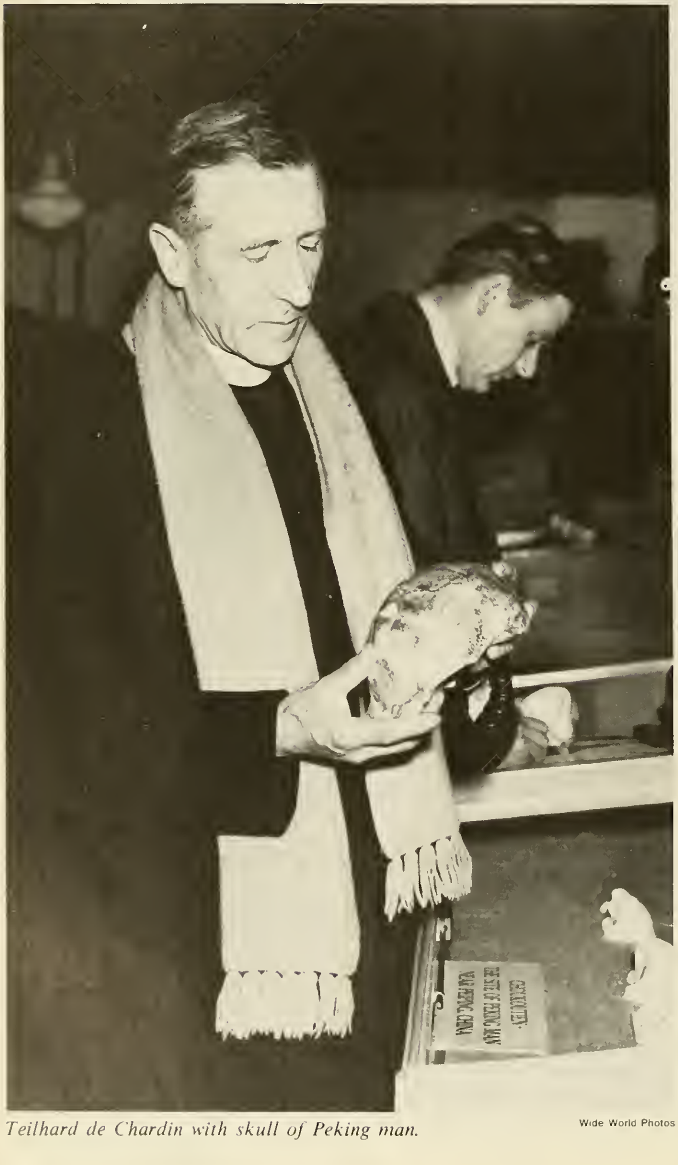
creatures had been mixed together at the Piltdown site. Smith Woodward stoutly defended the integrity of his creature, arguing, with flawed logic, that the crucial role of brain power in our mastery of the earth today implies a precocious role for large brains in evolutionary history as well. A fully vaulted skull still attached to an apish jaw vindicated such a brain-centered view of human evolution.

Teilhard left England late in 1912 to begin his graduate studies with Marcellin Boule, the greatest physical anthropologist of France. But in August 1913, he was back in England for a retreat at Ore Place. He also spent several days prospecting with Dawson and on August 30 made a major discovery himself—a canine tooth of the lower jaw, apish in appearance but worn in a human fashion. Smith Woodward continued his series of publications on the new material, but critics persisted in their belief that Piltdown man represented two animals improperly united.



*Teilhard de Chardin with skull of Peking man.*

Wide World Photos

The impasse broke in Smith Woodward's favor in 1915. Dawson had been prospecting at another site, two miles from Piltdown, for several years. He probably took Teilhard there in 1913; we know that he searched the area several times with Smith Woodward in 1914. Then, in January 1915, he wrote to Smith Woodward. The second site, later called Piltdown 2, had yielded its reward: "I believe we are in luck again. I have got a fragment of the left side [it was actually the right] of a frontal bone with a portion of the orbit and root of nose." In July of the same year, he announced the discovery of a lower molar; again, apish in appearance but worn in a human fashion. The bones of a human and an ape might wash into the same gravel pit once, but the second, identical association of vaulted skull and apish jaw surely proved the integrity of a single bearer, despite the apparent anatomical incongruity. H.F. Osborn, America's leading paleontologist and critic of the first Piltdown find, announced a conversion in his usual grandiloquent fashion. Even Teilhard's teacher Marcellin Boule, leader of the doubters, grumbled that the new finds had tipped the balance, albeit slightly, in Smith Woodward's favor. Dawson did not live to enjoy his triumph, for he died in 1916. Smith Woodward stoutly supported Piltdown for the rest of his long life, devoting his last book (*The Earliest Englishman*, 1948) to its defense. He died, mercifully, before his bubble burst.

Meanwhile, Teilhard pursued his calling with mounting fame, frustration, and exhilaration. He served with distinction as a stretcher bearer in World War I and then became professor of geology at the Institut Catholique of Paris. But his unorthodox (although always pious) thinking soon led him into irrevocable conflict with ecclesiastical authority. Ordered to abandon his teaching post and to leave France, Teilhard departed for China in 1926. There he remained for most of his life, pursuing distinguished research in geology and paleontology and writing the philosophical treatises on cosmic history and the reconciliation of science with religion that later made him so famous. (They all remained unpublished, by ecclesiastical fiat, until his death.) Teilhard died in 1955, but his passing only marked the beginning of his meteoric rise to fame. His treatises, long suppressed, were published and quickly translated into all major languages. *The Phenomenon of Man* became a best seller throughout the world. Harvard's Widener Library now houses an entire tier of books devoted to Teilhard's writing and thinking. Two journals that were established to discuss his ideas still flourish.

Of the original trio—Dawson, Teilhard, and Smith Woodward—only Teilhard was still living when Kenneth Oakley, J.S. Weiner, and W.E. le Gros Clark proved that the Piltdown bones had been chemically stained to mimic great age, the teeth artificially filed to simulate human wear, the associated mammal remains all brought in from elsewhere, and the flint "implements" recently carved. The critics had been right all along, more right than they had dared to imagine. The skull bones did belong to a modern human, the jaw to an orangutan. As the shock of revelation gave way to the fascination of whodunit, suspicion quickly passed from two members of the trio. Smith Woodward had been too dedicated and too gullible; moreover, he knew nothing of the site before Dawson brought him the original bones in 1912. (I have no doubt whatsoever of Smith Woodward's total innocence.) Teilhard was too famous and too present for any but the most discreet probing. He was dismissed as a naïve, young student who, forty years before, had been duped and used by the crafty Dawson. Dawson acting alone became the official theory; professional science was embarrassed, but absolved.

*Doubts*

I was just the right age for primal fascination—twelve years old—and a budding paleontologist when news of the fraud appeared on page one of the *New York Times* one morning at breakfast. My interest has never abated, and I have, over the years, asked many senior paleontologists about Piltdown. I have also remarked, both with amusement and wonder, that very few believed the official tale of Dawson acting alone. I noted, in particular, that several of the men I most admire suspected Teilhard, not so much on the basis of hard evidence (for their suspicions rested on what I regard as a weak point among the arguments), but from an intuitive feeling about this man whom they knew well,

# IN A FUEL-OBSESSED SOCIETY, IS IT BLASPHEMY TO SUGGEST THAT A CAR SHOULD BE FUN TO DRIVE?

What with the threat of the "Gas Line" eternally poised over our collective heads, our national preoccupation with fuel efficiency is perfectly understandable.

The question must be asked, however, does meeting the demands of the gas pump—not to mention the endless stream of safety and anti-pollution regulations—mean that we are doomed to suffer a generation of terminally boring automobiles?

If one accepts as fact the dismal cries of woe emanating from the automotive community, it would seem so.

Yet, if one drives the BMW 320i, it becomes apparent that this is not at all the case.

Indeed, while overcoming these seemingly insurmountable obstacles, the BMW 320i provides the sort of exhilarating performance enthusiasts have all but given up for lost.

### THE THRILL OF PERFORMANCE WITHOUT THE SIN OF GAS GUZZLING.

Even before the words "gas crisis" became a permanent part of the language, small, practical family sedans were not well known for their performance capabilities.

A truth which makes the 320i all the more remarkable.

Take a hair-raising curve and the legendary BMW suspension system—independent on all four wheels—flexes with an uncanny resiliency that makes one feel as if the car were slotted into the roadway.

Press the accelerator and the four-cylinder, 1.8-liter, fuel-injected, overhead cam engine responds in a manner that can only be described as exhilarating, even by pre-pollution control standards.

Yet, the 320i (with 5-speed standard transmission) delivers an impressive $\boxed{25}$ EPA estimated mpg, 36 estimated highway mileage and, based on these figures, an estimated mpg range of $\boxed{383}$ miles and a highway range of 551 miles.

(Naturally our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.)

### AN INTERIOR ENGINEERED FOR SERIOUS DRIVING.

Perhaps no more succinct an expression of engineering intelligence exists than the interior of the BMW 320i—each facet strategically planned to help prevent driver fatigue.

Vital controls are within easy reach. The tachometer, speedometer and ancillary instruments are well-marked, easy to read and set in a control panel that sweeps out to meet the driver.

Its front seats are designed to hold their occupants firmly in place, and are so thoroughly adjustable that it is all but impossible not to find a comfortable seating position.

All in all, in a time of lowered automotive expectations, amidst increasing mediocrity, the engineers at BMW have actually improved the BMW.

If you'd care to judge for yourself, phone your nearest BMW dealer to arrange a thorough test drive.

loved, and respected, but who seemed to hide passion, mystery, and good humor behind a garb of piety. A.S. Romer and Bryan Patterson, two of America's leading vertebrate paleontologists and my former colleagues at Harvard, often voiced their suspicions to me. Louis Leakey voiced them in print, without naming the name, but with no ambiguity for anyone in the know (see his autobiography, *By the Evidence*).

I finally decided to get off my butt and probe a bit after I wrote a column on Piltdown for other reasons (*Natural History*, March 1979). I read all the official documents and concluded that nothing excluded Teilhard, although nothing beyond his presence at Piltdown from the start particularly implicated him either. I intended to drop the subject or to pass it along to someone with a greater zeal for investigative reporting. But at a conference in France last September, I happened to meet two of Teilhard's closest colleagues, the leading paleontologist J. Piveteau and the great zoologist P.P. Grassé. They greeted my suspicions with a blustering "*incroyable*." Then Père François Russo, Teilhard's friend and fellow Jesuit, heard of my inquiries and promised to send me a document that would prove Teilhard's innocence—a copy of the letter that Teilhard had written to Kenneth Oakley on November 28, 1953. I received this letter in printed French translation (Teilhard wrote it in English) in October 1979 and realized immediately that it contained an inconsistency (a slip on Teilhard's part) most easily resolved by the hypothesis of Teilhard's complicity. When I visited Oakley at Oxford in April 1980, he showed me the original letter along with several others that Teilhard had written to him. We studied the documents and discussed Piltdown for the better part of a day, and I left convinced that Romer, Patterson, and Leakey had been right. Oakley, who had noted the inconsistency but interpreted it differently, agreed with me and stated as we parted: "I think it's right that Teilhard was in it." (Let me here express my deep appreciation for Dr. Oakley's hospitality, his openness, and his simple, seemingly inexhaustible kindness and helpfulness. I always feel so exhilarated when I discover—and it is not so rare as many people imagine—that a great thinker is also an exemplary human being.) Since then, I have sharpened the basic arguments and read through Teilhard's published work, finding a pattern that seems hard to reconcile with his innocence. My case is, to be sure, circumstantial (as is the case against Dawson or anyone else), but I believe that the burden of proof must now rest with those who would hold Father Teilhard blameless.

## The Case Against Teilhard

*The Letters to Kenneth Oakley*

The main virtue of truth, quite apart from its ethical value (which I hold to be considerable), is that it represents an infallible guide for keeping your story straight. The problem with prevarication is that, when the going gets complex or the recollection misty, it becomes very difficult to remember all the details of your invented scheme. Richard Nixon finally succumbed on a minor matter, and Sir Walter Scott spoke truly when he wrote the famous couplet: "Oh, what a tangled web we weave,/When first we practice to deceive!"

Teilhard made just such a significant slip on a minor point in his letter to Oakley. Teilhard offered no spon-

# Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village... help hardworking people in their fight for dignity... turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles. NH 8/0

My Name Is ______________________________ (please print)

Address ______________________________

City ______________ State ______________ Zip ______________

## Tell us how you want to help, by answering these questions:

### 1. What kind of child would you like to help?

☐ Boy ☐ Girl ☐ No preference

### 2. What geographical area are you interested in?

Urgent need exists in all the areas listed below, especially overseas. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

**I strongly prefer:**
- ☐ Africa
- ☐ Bangladesh
- ☐ Chicano (U.S.)
- ☐ Colombia
- ☐ Dominican Republic
- ☐ Honduras
- ☐ Indian (U.S.)
- ☐ Indonesia
- ☐ Inner Cities (U.S.)
- ☐ Israel
- ☐ Korea
- ☐ Lebanon
- ☐ Mediterranean
- ☐ Mexico
- ☐ Southern States (U.S.)
- ☐ Sri Lanka (Ceylon)

### 3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

### 4. Would you like to exchange correspondence?

If desired, correspondence can build a meaningful one-to-one relationship and provide a unique educational experience for the sponsored child. In areas where illiteracy is high, a village representative will keep you informed of the progress your child is making. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

### 5. Would you like information about the child's community?

Several times a year you can receive detailed reports on the activities and projects being undertaken in the community to benefit your sponsored child. These community reports show how your money is being used most effectively for permanent improvements to the child's environment—for health care, education, food production, nutrition, and community training. Would you like to receive such information?

☐ Yes ☐ No

### 6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $

☐ Monthly, $16 ☐ Semi-annually, $96

☐ Quarterly, $48 ☐ Annually, $192

### 7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (80.3%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

*(A complete audit statement is available upon request.)*

### 8. Would you rather make a contribution than become a sponsor of an individual child at this time?

☐ Yes, enclosed is my contribution of $______.

☐ Check here for general information about our unique programs for aiding impoverished children.

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. Subsidiary/Ehrenreich Photo-Optical Industries, Inc.

taneous recollections about Piltdown and responded only to Oakley's direct inquiries for help in establishing the forger's identity. He begins by congratulating Oakley "most sincerely on your solution of the Piltdown problem. Anatomically speaking, *'Eoanthropus'* [Smith Woodward's name for the Piltdown animal] was a kind of monster. . . . Therefore I am fundamentally pleased by your conclusions, in spite of the fact that, sentimentally speaking, it spoils one of my brightest and earliest paleontological memories."

Teilhard then stonewalls on the question of fraud. He refuses to believe it at all, declaring that Smith Woodward and Dawson (and, by implication, himself) were not the kind of men who could conceivably do such a thing. Is it not possible, he asks, that some collector discarded the ape bones on a gravel pit that legitimately contained a human skull, the product of a recent interment. Could not the iron staining have been natural, since the local water "can stain (with iron) at a remarkable speed." But Teilhard's notion can explain neither the artificial filing of the teeth to simulate human wear nor the crucial discovery of a second combination of ape and human at the Piltdown 2 site. In fact, Teilhard admits: "The idea sounds fantastic. But, in my opinion, no more fantastic than to make Dawson the perpetrator of a hoax."

Teilhard then goes on to discuss Piltdown 2 and, in trying to exonerate Dawson, makes his fatal error. He writes:

> He Dawson just brought me to the site of Locality 2 and explained me [*sic*] that he had found the isolated molar and the small pieces of skull in the heaps of rubble and pebbles raked at the surface of the field.

But this cannot be. Teilhard did visit the second site with Dawson in 1913, but they did not find anything. Dawson "discovered" the skull bones at Piltdown 2 in January 1915, and the tooth not until July 1915. And now, the key point: Teilhard was mustered into the French army in December 1914 and was shipped immediately to the front, where he remained until the war ended. He could not have seen the remains of Piltdown 2 with Dawson, unless they had manufactured them together before he left (Dawson died in 1916).

Oakley caught the inconsistency im-

PROFESSIONAL
FAKE BOOK
MORE THAN
1010 SONGS

# WHAT IS A 'FAKE' MUSIC BOOK?

(For Starters, It Has Over 1000 Songs In It!)

It contains every kind of song for every kind of occasion. Hit songs of today such as **Don't It Make My Brown Eyes Blue**... great standards like **I'll See You In My Dreams**... the hit show tunes like **Oklahoma!**... songs of the Roaring 20's such as **Five Foot Two!** It has Irish songs, folk songs, Italian songs, Hawaiian songs, great classical themes, sacred songs, rock n' roll songs, Christmas songs, movie songs, latin songs, patriotic songs, waltzes, marches, you name it! *It is the one songbook meant to fill every request.*

**CHOCK FULL OF HITS** It has four pounds, almost 500 pages, of *solid music*... with all the lyrics, melodies, and chord names. It contains a complete alphabetical listing *plus* a cross-reference listing by song category for the immediate location of any song. It is handsomely spiral bound so that it lies perfectly flat on your music stand, and has a durable leatherette textured cover. It was built to last through years of use.

**A MUSICIAN'S DREAM COME TRUE** Until recently, such books, if you could find them, were sold "under the table." And musicians would pay a great amount. But now we can *legally* bring you what those same musicians are calling the *greatest* fake book of them all...: **The Legit Professional Fake Book.**

**MONEY BACK GUARANTEE TOO!** If you do not agree that this book is everything we say it is and more... if you are not completely thrilled and delighted for any reason whatsoever, simply return it to us within 30 days, (it will take you a *full* 30 days just to get through it!), and we will send you a *complete* refund. When you think of all this music, 1010 great songs, *at less than 3¢ a song*, songs which sell for up to $2.00 each in stores, you realize what a great bargain this book is for just $25. It is a book which you will use and cherish over and over again in years to come, whether it's party time, or Christmas time, or just by yourself time at the piano.

**A GREAT GIFT IDEA!** If you are not a musician yourself, don't you know someone who would really love to have this book? It is truly a gift for all seasons.

**IT'S THE ONE BOOK EVERY MUSICIAN, PROFESSIONAL OR AMATEUR, MUST OWN.**

**IT'S WHAT PRO MUSICIANS CALL THE BIBLE.**

Here are just some of the **1010** songs you get...

**I Write The Songs ★ Feelings ★ Alley Cat ★ Copacabana**
**Deep Purple ★ Paper Roses ★ Tomorrow (from "Annie")**
**Don't It Make My Brown Eyes Blue ★ Moonlight Serenade**
**Just The Way You Are ★ We'll Sing In The Sunshine**
**I Left My Heart In San Francisco ★ It's Impossible ★ Laura**
**By The Time I Get To Phoenix ★ We've Only Just Begun**
**Blue Moon ★ Roses Are Red My Love ★ Don't Blame Me**
**City of New Orleans ★ El Paso ★ You Made Me Love You**
**Peg O' My Heart ★ Killing Me Softly With His Song**
**On A Clear Day ★ Who Can I Turn To ★ Bouquet Of Roses**
**Oklahoma ★ Bye Bye Love ★ Ruby ★ Somewhere My Love**
**Don't Be Cruel ★ Over The Rainbow ★ Unchained Melody**
**The Shadow Of Your Smile ★ If Ever I Would Leave You**
**Getting To Know You ★ My Blue Heaven ★ Toot Toot Tootsie**
**Gimme A Little Kiss ★ Blue Suede Shoes ★ Gigi**
**My Funny Valentine ★ Weekend in New England**
**My Favorite Things ★ Nobody Does It Better ★ Ebb Tide**

**SONGBOOKS UNLIMITED** • 352 Evelyn St., Paramus, NJ 07652

mediately when he received Teilhard's letter in 1953, but he read it differently and for good reason. At that time, Oakley and his colleagues were just beginning their explorations into whodunit. They rightly suspected Dawson and had written to Teilhard to gather evidence. Oakley read Teilhard's statement when he was simply trying to establish the basic fact of Dawson's guilt. In that context, he assumed that Dawson had shown the specimens to Teilhard in 1913, but had withheld them from Smith Woodward until 1915—more evidence for Dawson's complicity.

Oakley wrote back immediately, and Teilhard, realizing that he had tripped, began to temporize. In his second letter of January 29, 1954, he tried to recoup:

> Concerning the point of "history" you ask me, my "souvenirs" are a little vague. Yet, by elimination (and since Dawson died *during* the First World War, if I am correct) my visit with Dawson to the *second* site (where the two small fragments of skull and the isolated molar were supposedly found in the rubble) must have been in late July 1913 [it was probably in early August].

Obviously troubled, he then penned the following postscript.

> When I visited the site no. 2 (in 1913?) the two small fragments of skull and tooth had already been found, I believe. But your very question makes me doubtful! Yes, I think definitely they *had* been already found: and that is the reason why Dawson pointed to me the little heaps of raked pebbles as the place of the "discovery."

In a final letter to Mable Kenward, daughter of the owner of Barkham Manor, site of the first Piltdown find, Teilhard drew back even further: "Dawson showed me the field where the second skull (fragments) were found. But, as I wrote to Oakley, I cannot remember whether it was after or before the find" (March 2, 1954).

I can devise only four interpretations for Teilhard's slip.

1. I thought initially, when I had only read the first letter, that one might interpret Teilhard's statement thus: Dawson took me to the site in 1913 and later stated in wartime correspondence that he had found the fragments in the rubble. But Teilhard's second letter states explicitly that Dawson, in the flesh, had pointed to the spot at Piltdown 2 where he had found the specimens.

2. Oakley's original hypothesis: Dawson showed the specimens to an innocent Teilhard in 1913, but withheld them from Smith Woodward until 1915. But Dawson would not blow his cover in such a crude way. For Dawson took Smith Woodward to the second site on several prospecting trips in 1914, always finding nothing. Now Teilhard and Smith Woodward were also fairly close. Dawson had introduced them in 1909 by sending to London some important mammal specimens (having nothing to do with Piltdown) that Teilhard had collected. Smith Woodward was delighted with Teilhard's work and praised him lav-

ishly in a publication. He accepted Teilhard as the only other member of their initial collecting trips at Piltdown. Moreover, Teilhard was a house guest of the Smith Woodwards when he visited London in September 1913, following his discovery of the canine. If Dawson had shown Teilhard the Piltdown 2 finds in 1913, then led Smith Woodward extensively astray during several field trips in 1914, and if an innocent Teilhard had told Smith Woodward about the specimens (and I can't imagine why he would have held back), then Dawson would have been exposed.

3. Teilhard never did hear about the Piltdown 2 specimens from Dawson, but simply forgot forty years later that he had never actually viewed the fossils he had read about later. This is the only alternative (to Teilhard's complicity) that I view as at all plausible. Were the letters not filled with other damaging points, and the case against Teilhard not supported on other grounds, I would take this possibility more seriously.

4. Teilhard and Dawson planned the Piltdown 2 discovery before Teilhard left England. Forty years later, Teilhard misconstrued the exact chronology, forgot that he could not have seen the specimens when they were officially "found," and slipped in writing to Oakley.

Teilhard's letters to Oakley contain other curious statements, each insignificant (or subject to other interpretations) by itself, but forming in their ensemble a subtle attempt to direct suspicion away from himself.

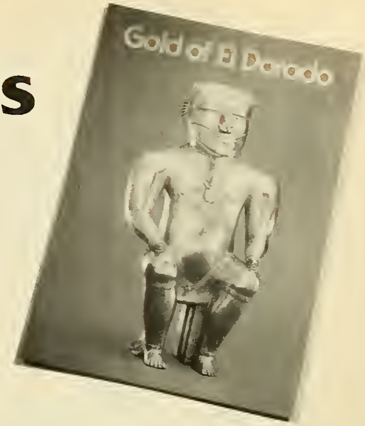
1. In his letter of November 28, 1953, Teilhard states that he first met Dawson in 1911. In fact, they met in May 1909, for Teilhard describes the encounter in a vivid letter to his parents. Moreover, this meeting was an important event in Teilhard's career, for Dawson befriended the young priest and personally forged his path to professional notice and respect by sending some important specimens he had collected to Smith Woodward. When Smith Woodward described this material before the Geological Society of London in 1911, Dawson, in the discussion following Smith Woodward's talk, paid tribute to the "patient and skilled assistance" given to him by Teilhard since 1909. I don't regard this, in itself, as a particularly damning point. A first meeting in 1911 would still be early enough for complicity (Dawson "found" his first piece of the Piltdown skull in 1911, although he states that a workman had given him a fragment "several years before"), and I would never hold a mistake of two years against a man who tried to remember the event forty years later. Still, the later (and incorrect) date, right upon the heels of Dawson's first "find," certainly averts suspicion from Teilhard.

2. Oakley wrote again in February 1954, probing further into Dawson's first contact with the Piltdown material, wondering in particular what had happened in 1908. Teilhard simply replied (March 1, 1954): "In 1908 I did not know Dawson." True enough, but they met just a few months later, and Teilhard might have mentioned it. A small point, to be sure.

3. In the same letter, Teilhard tries further to avert suspicion by writing of his years at Hastings: "You know, at that time, I was a young student in theology—not allowed to leave much his cell of Ore Place (Hastings)." But this description of a young, pious, and restricted man stands in stark contrast with the picture that Teilhard painted of himself at the time in a remarkable series of letters to his parents (*Lettres de Hastings et de Paris 1908–1912*, Paris: Aubier, 1965). These letters speak little of theology, but they are filled with charming and detailed accounts of Teilhard's frequent wanderings all over southern England. Eleven letters refer to excursions with Dawson, and no other naturalist is mentioned so frequently. If he spent much time at Ore Place, he didn't choose to write about it. On August 13, 1910, for example, he exclaims: "I have travelled up and down the coast, to the left and right of Hastings; thanks to the cheap trains [*les cheap-trains* as he writes in French] so common at this time of year, it is easy to go far with minimal expense."

Perhaps I am now too blinded by my own attraction to the hypothesis of Teilhard's complicity. Perhaps all these points are minor and unrelated, testifying only to the faulty memory of an aging man. But they do form an undeniable pattern. Still, I would not now come forward with my case were it not for a second argument, more circumstantial to be sure, but somehow more compelling in its persistent pattern of forty years—the rec-

# An Art Book That Took Centuries To Create



It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $8.95—a 28% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

ord of Teilhard's letters and publications.

*Piltdown in Teilhard's writing*

I remember a jokebook I had as a kid. The index listed "mule, sex life," but the indicated page was blank (ridiculous, in any case, for mules do not abstain just because the odd arrangement of their hybrid chromosomes debars them from bearing offspring). Teilhard's published record on Piltdown is almost equally blank. In 1920, he wrote one short article in French for a popular journal on *Le cas de l'homme de Piltdown.* After this, virtually all is silence. Piltdown never again received as much as a full sentence in all his published work (except once in a footnote). Teilhard mentioned Piltdown only when he could scarcely avoid it—in comprehensive review articles that discuss all outstanding human fossils. I can find fewer than half a dozen references in the twenty-three volumes of his complete works. In each case, Piltdown appears either as an item listed without comment in a footnote or as a point (also without comment) on a drawing of the human evolutionary tree or as a partial phrase within a sentence about Neanderthal man.*

Consider just how exceedingly curious this is. In his first letter to Oakley, Teilhard described his work at Piltdown as "one of my brightest and earliest paleontological memories." Why, then, such silence? Was Teilhard simply too diffident or saintly to toot his own trumpet? Scarcely, since no theme receives more voluminous attention, in scores of later articles, than his role in unearthing the legitimate Peking man in China.

As I began my investigation into this extraordinary silence, and trying to be as charitable as I could, I constructed two possible exonerating reasons for Teilhard's failure to discuss the major event of his paleontological youth. Kenneth Oakley then told me of the 1920 article, the only analysis of Piltdown that Teilhard ever published. I found a copy in the ten-volume edition of Teilhard's *oeuvre scientifique*, and realized that its content invalidated the only exculpatory arguments I could construct.

*The first argument:* Marcellin Boule, Teilhard's revered teacher, was a leading critic of Piltdown. He regarded it as a mixture of two creatures (not as a fraud), although he softened his opposition after he learned of the subsequent discovery at Piltdown 2. Perhaps Boule upbraided his young student for gullibility, and Teilhard, embarrassed to the quick, never spoke of the infernal creature, or of his role in discovering it, again.

The 1920 article invalidates such a conjecture, for in this work, Teilhard comes down squarely on the right side. He mentions that his English companions, convinced by finding the jaw so close to the skull fragments, never doubted the integrity of their fossil. Teilhard then notes, with keen insight, that experts who had not seen the specimens *in situ* would be swayed primarily by the formal anatomy of the bones themselves, and that these bones loudly proclaimed: human skull, ape's jaw. Which emphasis, then, shall prevail, geology or anatomy? Although he had witnessed the geology, Teilhard opted for anatomy:

> In order to admit such a combination of forms [a human skull and an ape's jaw in the same creature], it is necessary that we be forced to such a conclusion. Now this is not the case here. . . . The reasonable attitude is to grant primacy to the intrinsic morphological probability over the extrinsic probability of geological conditions. . . . We must suppose that the Piltdown skull and jaw belong to two different subjects.

Teilhard called it once, and he called it right. He had no reason to be embarrassed.

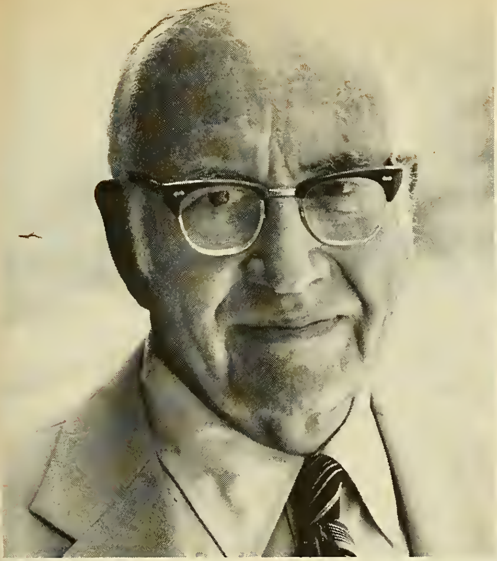
*The second argument:* Perhaps Teilhard had reveled in his role at Piltdown, cherished the memory, but simply found that the man he had helped to unearth could offer no support for, or even contact with, the concerns of his later career. On a broad level, this argument is implausible, if only because Teilhard wrote several general reviews about human fossils; however controversial or dubious, Piltdown should have been discussed. Even the leading doubters never failed to air their suspicions. Boule wrote chapters about Piltdown. Teilhard listed it without comment a few times and only when he had no choice.

In a more specific area, Teilhard's silence about Piltdown becomes inexplicable to the point of perversity (unless guilt and knowledge of fraud engendered it)—for Piltdown provided the best available support that fossils could provide for the most important argument of Teilhard's cosmic and mystical views about evolution, the dominant theme of his career and the source of his later fame. Teilhard never availed himself of his own best weapon, partly provided by his own hand.

The conclusion that skull and jaw belonged to different creatures did not destroy the scientific value of Piltdown, provided that both animals legitimately lay in the strata that supposedly entombed them. For these

---

*Teilhard's complete works are spread over two editions—a thirteen-volume edited compendium of his general articles (Paris: Editions de Seuil), and a more extensive ten-volume facsimile reprint of his professional publications (Olten: Walter-Verlag). To my annoyance, I discovered that the Paris edition has expurgated all Piltdown references without so stating and without even inserting ellipses. In trying to spiff up Teilhard's record, they have made him appear even more culpable by accentuating the impression of guilty silence. I therefore consulted likely originals whenever I could find them. One expurgation is particularly infuriating in its downright misrepresentation. A posthumous volume of essays, *Le Coeur de la matière* ("The heart of matter," Seuil, 1976), reprints Teilhard's application for the chair of paleontology at the Collège de France in 1948 (ecclesiastical authority did not permit him to accept). In this autobiographical essay, Teilhard discusses his role in human paleontology: "My first stroke of good luck in this area of ancient human paleontology came in 1923 when I was able to establish, with Emile Licent, the existence, hitherto contested, of paleolithic man in Northern China." If Teilhard had thus truly suppressed Piltdown in presenting himself for review, what but complicity could we infer? By sheer good fortune, I found a copy of this unpublished, mimeographed document in the reprint collection of my late colleague A.S. Romer. It reads: "My first stroke of good luck in this area of ancient human paleontology was to be included, when still young, in the excavation of *Eoanthropus dawsoni* in England. The second was, in 1923, to be able to establish, with Emile Licent. . . ." I doubt that half a dozen copies of the unpublished original exist in America, and I might easily have been led from the published and doctored version to an even stronger indication of Teilhard's complicity based on his silence. (It has, of course, occurred to me that the pattern of silence I detect in Teilhard's writing might represent more his editor's posthumous expurgation than Teilhard's own preference. Yet the completely honest ten-volume facsimile edition contains more than enough material to establish the pattern, and I have checked enough original versions of potentially expurgated texts to be confident that references to Piltdown are fleeting and exceedingly sparse throughout Teilhard's writing.)



# One of these drivers had a head-on collision and walked away without a scratch.

*"I'm Dr. Arnold Arms, the man on the left. In 1975, I drove one of the American cars equipped with air bag restraint systems being tested in this country. At 6 p.m. on October 7, I left my office to make a house call and never made it. I had a head-on collision with a city bus. I was travelling at about 25 miles an hour.*

*"I recall very well what happened. The air bag filled in front of the steering wheel and deflated right away. I could see I was alive. I could see that I had no broken bones. To my surprise, I didn't even have a headache or whiplash injury. I was able to walk away from the crash." Arnold V. Arms, M.D., Kansas City, MO*

In 1979, 25 million auto accidents occurred in the U.S. Millions of drivers and passengers were injured; 27,000 of them died. The cost of hospital and medical treatment for auto injuries was astronomical. And with inflation continuing to spiral, these costs continue to soar.

Many deaths and injuries could be prevented if people would use seat belts and shoulder harnesses, which are standard equipment in all new cars. Unfortunately, fewer than 20% of all automobile occupants use their seat belts.

A federal standard requires that all full-size 1982-model cars *automatically* protect front seat occupants from serious injury in crashes up to 30 mph.

The auto industry has proven technology to meet these new federal requirements. Safety belts that automatically restrain you is one approach. The air bag restraint system is another.

Extensive testing has proven that air bags can absorb the impact forces in head-on and front-angle crashes, with a cushioning effect that dramatically reduces serious injury. Research has shown that air bag protection can reduce the frequency of head, face, neck and torso injuries by as much as 40%. And the cost is less than many car stereo systems.

Air bag protection is automatic. No initiative is needed from the occupant. However, manual lap belts will still be provided for those who desire additional protection in other than front-angle crashes.

If there are fewer injuries, there will be less medical, hospital and legal expenses. And we will be better able to keep the cost of your auto insurance at a reasonable, affordable level.

**Here's what we're doing to control costs:**

- Working through the Insurance Institute for Highway Safety to make cars more crash resistant and highways safer.
- Lowering premiums for cars with air bag or automatic seat belt restraint systems.
- Asking for stricter enforcement of the 55 mph speed limit.
- Encouraging increased use of safety belts.

**Here's what you can do:**

- Use your seat belt regularly.
- Work in your community to make sure speed laws are enforced.
- Don't drink if you're going to drive.

## Affordable insurance is our business...and yours.

The original, indispensable

# KLUGE BAG™

## The "No-Waiter"

**A six piece set in one easy to carry-on ...for overnight or around the world.**

*Two time TV Emmy Award Winner Stan Hart: "The Kluge Bag is the best. The only piece of luggage I ever use."*

*Pennsylvania cattleman Robert Johnson: "For quality, convenience, organization, the Kluge Bag tops any set of luggage I've ever used."*

*DRG Record Company President Hugh Fordin: "One carry-on piece sure beats three or four check-in bags. I'm delighted."*

Here's the famous original you'll see on the Concorde, the shuttle to Washington, the commuter out of O'Hare. The Kluge Bag. The only combination overnighter and fortnighter in the world.

And the only bag that's as easy to carry to the last airline gate with a complete wardrobe as it is with a single change of clothing.

A "no waiter" you never check in. Never have to wait for at the baggage counter.

### Extra Comfort and Convenience

You'll use the Kluge Bag like a week-ender, too, because it's just as easy to carry on and a whole lot better. Better because nothing gets wrinkled or creased...because you have extra room for all the reports and papers you need, the tennis things you may or may not use, the sweater you'd like to be able to knock around in at night, and to bring back anything from reports to a new suit you pick up on your trip. (You can prove it yourself at our risk!)

### Beautifully Organized

The almost infinite flexibility is the result of an organization system designed by Peter Kluge, an international businessman, who travels constantly, from Chicago to Dallas, New York, Los Angeles, to Europe and the Middle East, never sure if he'll be away two days or two weeks, or of the clothing he'll need.

So, in one lightweight, compact, easy-to-carry handle or shoulder bag you get (1) a garment bag that holds two suits, (2) a pullman case, (3) a week-ender, (4) a tote-tennis bag, (5) a toilet-accessories kit, (6) a laundry-wet stuff bag...plus a full-size portfolio. Compartmentalized for easy access to your shirts, ties and belts; shoes and socks; underwear; suits, slacks and jackets; sportswear, sweater, bathrobe; business reports and papers. Anything and everything you need.

### One Vs. Two, Three or Four

You can't even begin to compare the ease and convenience of the Kluge (rhymes with huge) Bag with the bulky, heavy, loaded-down check-in luggage you usually carry on trips of three, four or more days.

The Kluge Bag alone easily outcarries a garment bag, a weekender or pullman plus a dispatch case. It not only looks better, weighs less, it's also much easier to carry and leaves your hands free to get your wallet or ticket. The Kluge Bag comes with a specially designed hook which allows you to hang it in the garment compartment of the plane. Most important of all, only the Kluge Bag is always ready when you are to get off the plane.

### Top Quality Construction

Simply, there's no other piece of luggage anything like this. Beautifully made of top-quality cellulose rayon, the material that's most often used in expensive luggage today because it's as strong as it is light, and will retain its beauty through years of use and abuse, the Kluge Bag is available in natural canvas color with rich brown piping and in striking solid black diamond and brown trim.

Outside there are three sectional zippers, so you can get to anything in a second, with security snap locks and an over-all snap lock safety strap, plus comfortable carrying handles and the adjustable burden-bearing shoulder strap.

Inside, a fold-up rigid bottom supports everything you can carry in the zippered main compartment. The fittings and details are equally impressive, like a tie rack, a fitted compartment for toiletries, a zippered compartment for valuables, pockets for cards, notes, keys and more. Plus a huge volume portfolio. Everything you need to make packing and traveling for days or weeks easier and faster than it's ever been before. Yet fully packed the Kluge Bag is just 18" high by 23" long and 12" deep.

**Unique Shoulder Carry System**

### Only $49.95!

Most extraordinary of all, though, is the price. At **$90** and $100, which is the price you'd probably have to spend in a fine retail store, the Kluge Bag would be an excellent value. At **$49.95** plus $3.60 shipping and handling, it's absolutely unbeatable.

A price that's possible because we're able to commit for an entire manufacturing run, and to eliminate salesmen, distributors and retailers and their costs by selling direct.

### No Risk Trial

Now we invite you to judge the Kluge Bag for yourself—for 30 days without risk or obligation. You must be convinced that it's the finest, most useful, convenient and versatile piece of luggage on the market today, a time and trouble saver, the perfect piece for every trip, or return it to us for a complete refund. No questions asked.

## Call 800-228-5959

Nebraska Residents Call 800-642-8777
(In operation 24 hours, 7 days a week)

To order with any credit card, just call us at the *toll free* number above. Or send your check to Dimensions Unlimited, Inc. at the address below. Be sure to specify natural or black. (Illinois residents are required to include 5% sales tax.)

Of course we want you to try it on a trip during your 30-day trial. Don't worry about how you handle it. Nothing will hurt it. And we'll take it back under any circumstances anyway. So order your Kluge Bag right now. Take the lug out of luggage, the wait out of baggage.

The Kluge Bag is also available with rich belting leather trim. The price is just **$70.00** plus $3.60 shipping and handling. To order with any credit card, just call us at the toll-free number above. Or send your check to Dimensions Unlimited, Inc. at the address below. Be sure to specify natural or black, regular or deluxe.

strata were older than any housing Neanderthal man, Europe's major claim to anthropological fame. Neanderthal, although now generally considered as a race of our species, was a low-vaulted, beetle-browed fellow of decidedly "primitive" cast. Piltdown, despite the thickness of its skull bones, looked more modern in its globular vault. The assignment of the jaw to a fossil ape further enhanced the skull's advanced status. Humans of modern aspect must have lived in England even before Neanderthal man evolved on the continent. Neanderthal, therefore, cannot be an ancestral form; it must represent a side branch of the human tree. Human evolution is not a ladder but a series of lineages evolving along separate paths.

In the 1920 article, Teilhard presented the Piltdown skull, divorced from its jaw, in just that light—as proof that hominids evolved as a bundle of lineages moving in similar directions. He wrote:

> Above all, it is henceforth proved that even at this time [of Piltdown] a race of men existed, already included in our present human line, and very different from those that would become Neanderthal.... Thanks to the discovery of Mr. Dawson, the human race appears to us even more distinctly, in these ancient times, as formed of strongly differentiated bundles, already quite far from their point of divergence. For anyone who has an idea of paleontological realities, this light, tenuous as it appears, illuminates great depths.

To what profundity, then, did Teilhard refer Piltdown as evidence? Teilhard believed that evolution moved in an intrinsic direction representing the increasing domination of spirit over matter. Under the thrall of matter, lineages would diverge to become more unlike, but all would move upward in the same general direction. With man, evolution reached its crux. Spirit had begun its domination over matter, adding a new layer of thought—the noosphere—above the older biosphere. Divergence would be stemmed; indeed, convergence had already begun in the process of human socialization. Convergence will continue as spirit prevails. When the last vestiges of matter have been discarded, spirit will involute upon itself at a single point called Omega and identified with God—the mystical evolutionary apocalypse that secured Teilhard's fame.

But convergence is a thing of the future. Scientists seeking evidence for such a scheme must look to the past for twin signs of divergence accompanied by similar upward direction—in other words, for *multiple, parallel lineages* within larger groups.

I have read all of Teilhard's papers from the early 1920s. No theme receives more emphasis than the search for multiple, parallel lineages. In an article on fossil tarsiers, written in 1921, he argues that three separate primate lineages extend back to the dawn of the age of mammals, each evolving in the same direction of larger brains and smaller faces. In a review published in 1922 of Marcellin Boule's *Les Hommes fossiles*, Teilhard writes: "Evolution is no more to be represented in a few simple strokes for us than for other living things; but it resolves itself into innumerable lines which diverge at such length that they appear parallel." In a general essay on evolution, printed in 1921, he speaks continually of oriented evolution in multiple, parallel lines within mammals.

But where was Piltdown in this extended paean of praise for multiple, parallel lineages? Piltdown provided proof, the only available proof, of multiple, parallel lineages within human evolution itself—for its skull belonged to an advanced human older than primitive Neanderthal. Piltdown was the most sublime argument that Teilhard possessed, and he never breathed it again after the 1920 article.

These two arguments have been abstract. A third feature of the 1920 article is stunning in its directness. For I believe that Teilhard fleetingly tried to tell his colleagues, too subtly perhaps, that Piltdown was a phony. In discussing whether the Piltdown remains represent one or two animals, Teilhard laments that the direct and infallible test cannot be applied. One skull fragment contained a perfect glenoid fossa, the point of articulation for the upper jaw upon the lower. Yet the corresponding point of the lower jaw, the condyle, was missing on a specimen otherwise beautifully preserved at its posterior end. Teilhard writes: "Since the glenoid fossa exists in perfect state on the temporal bone, we could simply have tried to articulate the pieces, *if the mandible had preserved its condyle:* we could have learned, without possible doubt, if the two fit together." I read this statement in a drowsy state one morning at two o'clock, but the next line—set off by Teilhard as a paragraph in itself terminated by an exclamation point—destroyed any immediate thought of sleep: "As if on purpose [*comme par exprès*], the condyle is missing!"

*"Comme par exprès."* I couldn't get those words out of my mind for two days. Yes, it could be a literary line, a permissible metaphor for emphasis. But I think that Teilhard was trying to tell us something he didn't dare reveal directly.

*Other Arguments*

1. Teilhard's embarrassment at Oakley's disclosure. Kenneth Oakley told me that, although he had not implicated Teilhard in his thoughts, one aspect of Teilhard's reaction had always puzzled him. All other scientists, including those who had cause for the most profound embarrassment (like the aged Sir Arthur Keith, who had used Piltdown for forty years as the bedrock of his thought), expressed keen interest amidst their chagrin. They all congratulated Oakley spontaneously and thanked him for resolving an issue that had always been puzzling, even though the solution hurt so deeply. Teilhard said nothing. His congratulations arrived only when they could not be avoided–in the preface to a letter responding to Oakley's direct inquiries. When Teilhard visited London, Oakley tried to discuss Piltdown, but Teilhard always changed the subject. He took Teilhard to a special exhibit at the British Museum illustrating how the hoax had been uncovered. Teilhard glumly walked through as fast as he could, eyes averted, saying nothing. (A.S. Romer told me several years ago that he also tried to conduct Teilhard through the same exhibit, and with the same strange reaction.) Finally, Teilhard's secretary took Oakley aside and explained that Piltdown ws a sensitive subject with Father Teilhard.

But why? If he had been gulled by Dawson at the site, he had certainly recouped his pride. Smith Woodward had devoted his life to Dawson's concoction. Teilhard had written about it but once, called it as correctly as he could, and then shut up. Why be so embarrassed? Unless, of course, the embarrassment arose from guilt about another aspect of his silence—his inability to come clean while he watched men he loved and respected make fools of themselves, partly on his account. Marcellin Boule, his beloved master, for example, correctly called Smith

Woodward's *Eoanthropus* "an artificial and composite being" in the first edition of *Les Hommes fossiles* (1921). The skull, he said, could belong to *"un bourgeois de Londres"*; the jaw belonged to an ape. But he pondered the significance of Piltdown 2 and changed his mind in the second edition of 1923: "In the light of these new facts, I cannot be as sure as I was before. I recognize that the balance has now tipped a bit in the direction of Smith Woodward's hypothesis—and I am happy for this scientist whose knowledge and character I esteem equally." How did Teilhard feel as he watched his beloved master, Boule, falling into the abyss—when he contained tools for extraction that he could not use.

2. The elephant and the hippo. Bits and pieces of other fossil mammals were salted into the Piltdown gravels in order to set a geologic matrix for the human finds. All but two of these items could have been collected in England. But the hippo teeth, belonging to a distinctive dwarfed species, probably came from the Mediterranean island of Malta. The elephant tooth almost surely came from a distinctive spot at Ichkeul, Tunisia, for it is highly radioactive as a result of seepage from surrounding sediments rich in uranium oxide. This elephant species has been found in several other areas, but nowhere else in such highly radioactive sediments. Moreover, the Ichkeul site was only discovered by professionals in 1947; the doctored specimen at Piltdown could not have come from a cataloged museum collection.

Teilhard taught physics and chemistry at a Jesuit school in Cairo from 1905 to 1908, just before coming to Piltdown. His volume of *Letters from Egypt* again records little about theology and teaching, but much about travel, natural history, and collecting. He did not call at Tunisia or Malta on his passage down, but I can find no record of his passage back, and the two areas are right on his route from Cairo to France. In any case, Teilhard's letters from Cairo abound in tales of swapping and exchange with other natural historians of several North African nations. He was plugged into an amateur network of information and barter and might have received the teeth from a colleague.

This argument formed the base of evidence among my senior colleagues who suspected Teilhard—A.S. Romer, Bryan Patterson, and Louis Leakey (Leakey also mentioned Teilhard's knowledge of chemistry and the clever staining of the Piltdown bones). According to hearsay, le Gros Clark himself, a member of the trio that exposed the hoax, also suspected Teilhard on this basis. I regard this argument as suggestive, but not compelling. Dawson too was plugged into a network of amateur exchange.

3. Teilhard's good luck at Piltdown. Although records are frustratingly vague, I believe that all the Piltdown pieces were found by the original trio—Dawson, Smith Woodward, and Teilhard. (In the official version, a workman may have given Dawson the first piece in 1908.) Dawson, of course, unearthed most of the material himself. Smith Woodward, so far as I can tell, found only one cranial fragment. Teilhard, who spent less time at Piltdown than his two colleagues, was blessed. He found a fragment of the elephant tooth, a worked flint, and the famous canine.

People who have never collected in the field probably do not realize how difficult and chancy the operation is when fossils are sparse. There is no magic to it, just hard work. A tooth in a gravel pit is about as conspicuous as the proverbial needle in a haystack. The hoaxer worked hard on his Piltdown material. He filed the canine and painted it to simulate age. Apes' teeth are not easy to come by. If I had but one precious item, I would not stick it into a large gravel heap and then hope that some innocent companion would find it. It would probably be lost forever, not triumphantly recovered. I doubt that I would ever find it again myself, after someone else had mucked about extensively in the pile.

Teilhard described his discovery in the first letter to Oakley: "When I found the canine, it was so inconspicuous amidst the gravels which had been spread on the ground for sifting that it seems to me quite unlikely that the tooth could have been planted. I can even remember Sir Arthur congratulating me on the sharpness of my eyesight." Smith Woodward's recollection (from his last book of 1948) is more graphic:

> We were excavating a rather deep and hot trench in which Father Teilhard, in black clothing, was especially energetic; and, as we thought he seemed a little exhausted, we suggested that he should leave us to do the hard labor for a time while he had comparative rest in searching the rain-washed spread gravel. Very soon he exclaimed that he had picked up the missing canine tooth, but we were incredulous, and told him we had already seen several bits of ironstone, which looked like teeth, on the spot where he stood. He insisted, however, that he was not deceived, so we both left our digging to go and verify his discovery. There could be no doubt about it, and we all spent the rest of that day until dusk crawling over the gravel in the vain quest for more.

I also have some doubt about Teilhard's flint, for it is the only Piltdown item indubitably found *in situ*. All the other specimens either came from gravel heaps that had been dug up and spread upon the ground or cannot be surely traced. Now *in situ* can signify one of two things (and the records do not permit a distinction). It may mean that the gravel bed lay exposed in a ditch, cliff, or road cut—in which case, anyone might have stuck the flint in. But it may mean that Teilhard dug into the layer from undisturbed, overlying ground—in which case, he could only have planted the flint himself.

Again, I regard this argument only as suggestive, not as definitive. It is the weakest point of all, hence its place at the botton of my list. Perhaps Teilhard was simply a particularly keen observer.

### Conclusions

What shall we make of all this? I can only imagine three conclusions. First, perhaps Piltdown has simply deluded another gullible victim, this time myself. Maybe I have just encountered an incredible string of coincidences. Could all the slips in the letters have been innocent errors of an aging man; the *comme par exprès* merely a literary device; the failure to use his best argument a simple oversight; his conspicuous silence beyond a few fleeting and unavoidable mentions only an aspect of a complex personality that no one has fathomed; his profound embarrassment just another facet of the same personality; the elephant and hippo Dawson's property . . . ? I just can't believe it. Coincidences recede into improbability as more and more independent items coagulate to form a pattern. The mark of any good theory is that it makes coordinated sense of a string of observations otherwise independent and

GO ECLECTIC

QPB brings you the best from a variety of sources. Classic, contemporary. Fiction and nonfiction. Practical books. Poetry, humor, history.

All are printed on fine paper in readable type. And all are as durably bound as their hardcover counterparts, but cost up to 65% less. Go eclectic—go QPB.

inexplicable. Let us then assume that Teilhard knew Piltdown was a hoax, at least from 1920.

We are left with two possibilities. Was Teilhard innocent in the field at Piltdown? Did he tumble to the hoax later (perhaps when he deciphered the inconsistencies in Piltdown 2)? Did he then maintain silence out of loyalty to Dawson who had befriended him or because he didn't wish to stir a hornet's nest when he was not completely sure? But why, then, did he try so hard to exonerate Dawson in the letters to Oakley? For Dawson had used him and played on his youthful innocence as cruelly as he had deceived Smith Woodward. And why did he write a series of slips and half-truths to Oakley that embody, as their only pattern, an attempt to extract himself alone? And why such intense embarrassment and such conspicuous silence if he had guessed right but had been too unsure to say so?

Alan Ternes, editor of *Natural History*, made the interesting suggestion that Teilhard, as a priest, might have heard of the hoax through a confession by Dawson that he could not subsequently reveal. I have not been able to ascertain whether Dawson was Catholic; I do not think that he was. But I am told that priests may regard statements of contrition by other baptized Christians as privileged information. This is the most sensible version I have heard of the hypothesis that Teilhard knew about the fraud but did not participate in it. It would explain his silence, his embarrassment, even the "*comme par exprès*." But, in this case, why would Teilhard have tried to construct such an elaborate and farfetched theory of Dawson's innocence in his first letter to Oakley. Confession may have required silence, but surely not sheltering by falsehood. Any why the slips and half-truths for his own exoneration in the subsequent letters?

This leaves a third explanation—that Teilhard was an active coconspirator with Dawson at Piltdown. Only in this way can I make sense of the pattern in Teilhard's letters to Oakley, the 1920 article, the subsequent silence, the intense embarrassment.

This conclusion raises two final issues. First, to cycle back to my introduction, conspiracies have a tendency to spread. Once we admit Teilhard into the plot, should we not wonder about others as well? In fact, several knowledgeable people have strong suspicions about some young subordinates in the British Museum. I have confined my work to Teilhard's role; I think that others may have participated.

Second, what about motive? However overwhelming, the evidence cannot satisfy us without a reasonable explanation for why Teilhard might have done such a thing. Here I see no great problem, although we must recast Piltdown (at least from Teilhard's standpoint) as a joke that went too far, not as a malicious attempt to defraud.

Teilhard was not the dour ascetic or transported mystic that his publications sometimes suggest. He was a passionate man—a genuine hero in war, a true adventurer in the field, a man who loved life and people, who strove to experience the world in all its pleasures and pains. I assume that Piltdown was merely a delicious joke for him—at first. At Hastings, he was an amateur natural historian, with no expectation of a profesional career in paleontology. He probably shared the attitude toward professionals so common among his colleagues—there but for the vagaries of life go I. Why do they have the fame, the reputation, and the cash? Why do they sit at their desks and reap rewards while we, with deeper knowledge born of raw experience, amuse ourselves? Why not play a joke to see how far a gullible professional could be taken? And what a wonderful joke for a Frenchman, for England at the time boasted no human fossils at all, while France, with Neanderthal and Cro-Magnon, stood proudly as the queen of anthropology. What an irresistible idea—to salt English soil with this preposterous combination of a human skull and an ape's jaw and see what the pros could make of it.

But the joke quickly went sour. Smith Woodward tumbled too fast and too far. Teilhard was posted to Paris to become, after all, a *professional* paleontologist. The war broke out, and Teilhard had to leave just as the last act to quell skepticism, Piltdown 2, approached the stage. Then Dawson died in 1916, the war dragged on to 1918, and professional English paleontology fell further and further into the quagmire of acceptance. What could Teilhard say by the war's end? Dawson could not corroborate his story. The jobs and careers of other conspirators may have been on the line. Any admission on Teilhard's part would surely have wrecked irrevocably the professional career he had desired so greatly, dared so little to hope for, and at whose threshold he now stood with so much promise. What could he say beyond *comme par exprès*.

Shall we then blame Teilhard or shall we forgive him? We cannot simply laugh and forget. Piltdown absorbed the professional attention of many fine scientists. It led millions of people astray for forty years. It cast a false light upon the basic processes of human evolution. Careers are too short and time too precious to view so much waste with equanimity.

But who among us would or could have come clean in Teilhard's position? Unfortunately, intent does not always correlate with effect in our complicated world—yet I believe that we must judge a man primarily by intent. If Teilhard had acted for malice or in hope of reward, I would have no sympathy. But I cannot view his participation as more than an intended joke that unexpectedly turned to a galling bitterness almost beyond belief. I think that Teilhard suffered for Piltdown throughout his life. I believe that he must have cried inwardly as he watched Smith Woodward and even Boule himself make fools of themselves—the very men who had befriended and taught him. Could the anguish of Piltdown have been on his mind, when he made the following pledge from the trenches during World War I.

> I have come, these days, to realize one very elementary fact: that the best way to win some sort of recognition for my ideas would be for me myself to attain, in the truest possible sense of the word, to a "sanctity" that will be manifest to others—not only because of the particular force God would then give to whatever good is in my aspirations and influence—but also because nothing can give me more authority over men than for them to see me as someone who speaks to them from close to God. With God's help, I must live my "vision" fully, logically, and without deviation. There is nothing more infectious than the example of a life governed by conviction and principle. And now I feel sufficiently drawn to and sufficiently equipped for, such a life.

Teilhard paid his debt and lived a full life; may we all do so well.

# HOW TO SAVE FUEL DURING YOUR SUMMER VACATION

**ENGINE TUNING, TIRE PRESSURE, AND HOW YOU DRIVE MAKE A BIG DIFFERENCE.**

You're sure to be on the move this summer. With gas more expensive, you may find helpful a few simple reminders on the best ways to get maximum mileage. They won't take a lot of time, and may save you a fair amount at the gas pump.

**A car that is properly tuned and maintained will be the most fuel-efficient.** Newer GM cars require less routine maintenance than older ones, but all cars require some periodic checkups. Fouled spark plugs, improper spark timing or clogged oil and air filters all can reduce mileage significantly. So be sure to follow the maintenance program in your GM Owner's Manual and Maintenance Schedule.

**Underinflated tires waste lots of gas.** Tires that are too soft have a higher rolling resistance, which forces the engine to work harder and to use more fuel. So have the tire pressures checked periodically, or use a tire gauge yourself, to be sure your tires are inflated to the pressure recommended in the GM Owner's Manual.

**Use your air conditioner prudently.** Whenever possible, use the vent position on the air conditioner to circulate air; it's not only quieter and cleaner than opening the windows all the way, but your car presents less wind resistance with the windows up. If you park in the shade, your car will be cooler when you get in, so it'll be easier to keep comfortable without making the air conditioner work so hard.

**Keeping the proper amount of coolant in the radiator will help prevent your car from overheating.** It won't save fuel, but it may save expensive towing costs. A lot of people think it's okay just to add extra water, but that can actually cause the mixture in your radiator to boil. Coolant—a 50/50 mixture of ethylene glycol antifreeze and water—raises the boiling temperature and will therefore help prevent overheating.

**Your driving habits are probably the most important factor of all in saving fuel.** The best advice we can give is to drive at moderate speeds and accelerate evenly. For example, jackrabbit starts take much more gasoline than gradual acceleration. Frequent stops will also cost you fuel, because every "pump" of the accelerator means extra gas going through the carburetor. Also, "riding the brake" creates a lot of unnecessary friction and wastes gas.

Extra weight in your trunk, such as tire chains, golf clubs you don't plan to use, even unnecessary luggage, takes more gas to haul. And finally, driving at high speeds substantially reduces fuel economy. So observing the 55 mile per hour speed limit makes economic sense and may save lives, too. Tests confirm that you can get approximately 20% better mileage by driving at 50 miles per hour than at 70 miles per hour.

Attention to routine maintenance and moderation in how you drive are the keys to getting the best mileage from your car during this summer. That'll save you money and help make sure that there's enough gas for others to enjoy a summer vacation, too.

# Where Have All the Curlews Gone?

*One species seems to have gone extinct, although occasional sightings of the Eskimo curlew keep hopes alive*

**by Paul A. Johnsgard**

The morning of September 16, 1932, dawned gray and dismal, with a northeaster in full progress along the coast of Long Island. The night before, Robert Cushman Murphy, the noted authority on coastal and sea birds, and his family had camped near the lighthouse at the tip of Montauk Point. Shortly after daylight four large shorebirds headed in from the direction of the sea and dropped into the vegetation of a hillock near Murphy's tent. Stalking the birds, Murphy could scarcely believe his eyes. They were almost certainly Eskimo curlews, a species believed by some to be extinct, and had probably come from the coast of Labrador, where a curlew had been shot two weeks previously near the Strait of Belle Isle. So far as is known, that was the last Eskimo curlew ever shot on the North American continent, and Murphy's observation was to be the last along the Atlantic coast for nearly thirty years.

Those four remnant birds were following one of the most remarkable migration patterns of all the North American shorebirds. They were representatives of a species once so abundant that flocks on the Labrador coast were reported to be a mile long and nearly as wide. The calls of a distant flock were said to sound like the wind whistling through a ship's rigging or the jingling of countless sleigh bells. When the birds arrived from central Canada in August, they gorged themselves on the abundant invertebrates and crowberries of the Labrador coast in preparation for the long overseas flight to their wintering areas. If the fall weather was favorable, the birds remained in Newfoundland and Nova Scotia until early September, when they would leave for a nonstop flight to the Lesser Antilles, some 2,000 miles to the south. After a brief layover in the Lesser Antilles, the birds continued south over eastern Brazil and on to Argentina. The majority arrived at their winter quarters by mid-September, concentrating in the grassy pampas south of Buenos Aires.

However, fall storms on the Atlantic coast often affected this schedule and itinerary, forcing the birds to hug the North American shoreline. Large flocks would build up along the Atlantic coast, particularly in Massachusetts, on Long Island, and down through the Middle Atlantic and southern states. (Local hunters in New England called the curlews "doughbirds," apparently because they were so fat and tender.) Under adverse weather conditions, some flocks sought refuge on Bermuda. Westerly winds sometimes drove them far out over the Atlantic, and on rare occasions they would touch down in the British Isles.

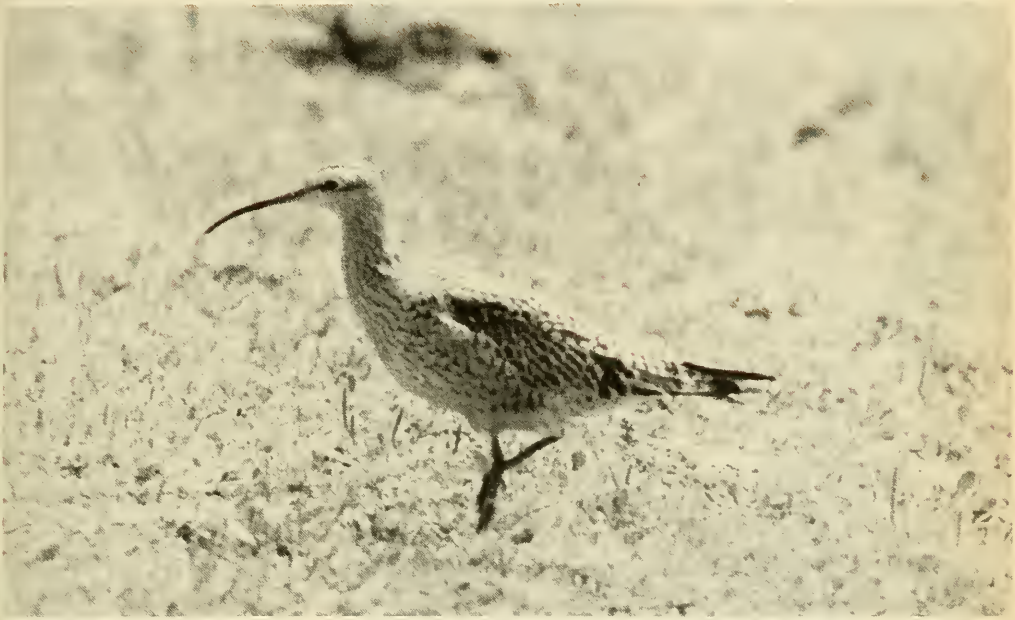
Such large assemblages of birds did not go unnoticed by hunters, who ruthlessly slaughtered thousands in Labrador every fall. The Hudson's Bay Company's store at Cartwright was a convenient place to sell the tasty birds, which were marketed in all eastern cities, and it was not unusual for twenty-five or thirty hunters to bring in as many as 2,000 curlews in a single day. Individual hunters often shot hundreds, usually by stationing themselves between feeding areas and simply waiting for the birds to pass by. The curlews' favored foraging areas were muddy tidal flats where small mollusks were abundant; these, together with crowberries, seem to have been the bulk of their autumnal foods. The birds were so intent on reaching the tidal flats that they continued to circle even when subjected to steady gunfire.

Such slaughter could not go on indefinitely. Between 1870 and 1880 the birds began to diminish rapidly, and by 1890 they had been practically exterminated on the Labrador coast. In that same year, however, a "cloud" of these curlews was observed on the Magdalen Islands in the Gulf of Saint Lawrence, the last sighting of a large flock anywhere. By 1900 the birds were nearly gone. An ornithologist who visited the Labrador coast in the fall of that year saw only five birds there and could find evidence for only about twelve for the entire area. Eight were seen in the fall of 1912 on the Labrador coast, of which all but one were shot.

Fall hunting was not the only hazard for the birds. Those that survived the long fall migration were also hunted without restriction in the South American wintering areas, although the intensity of hunting there was not nearly so great as in North America.

The Eskimo curlew's traditional spring migration route was quite different from the fall pattern. By late February or early March the birds left their wintering areas and probably undertook a nonstop flight to the Gulf Coast of the United States. They initially concentrated in the coastal prairies of Texas and Louisiana in early or mid-March and gradually moved northward through the southern Great Plains. They began arriving in Oklahoma in late March, and by early April they were abundant in Kansas, western Missouri, western Iowa, and Nebraska, as well as Oklahoma. These great spring flocks reminded the pioneers of passenger pigeons, and the birds were often called "prairie pigeons." They foraged and migrated in vast flocks; in flight these might reach a half mile in length and a hundred yards or more in width. When feeding in fields they frequently covered areas of forty to fifty acres. The largest flocks assembled during the period of corn planting, when the birds settled on newly plowed fields or burned-off prairie searching for grasshopper eggs, young grasshoppers, and other insects.

Market hunters from such cities as Saint Louis, Kansas City, and Omaha ravaged these flocks without mercy. Wagons brought from Omaha were literally filled with curlews. When they were shot for sport, the birds were simply dumped wholesale on the prairie, their bodies forming heaps as large as several tons of coal. Here, too, the birds circled in masses so dense that one "could scarcely throw



Don Bleitz

a brick or other missile into it without striking a bird," according to Myron Swenk, summarizing the species' decline in the Smithsonian Institution's Annual Report for 1915.

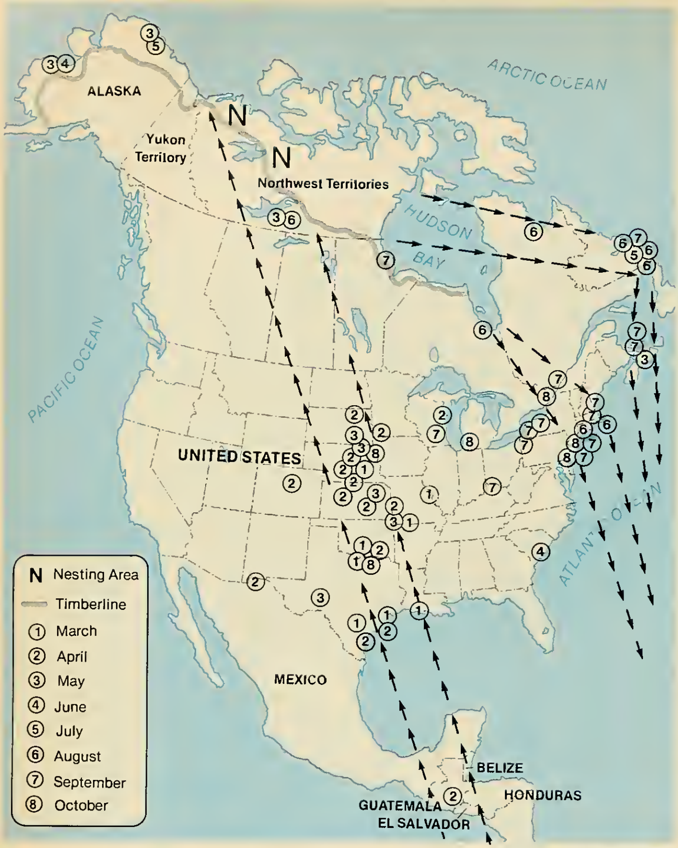
By mid-May, the birds were moving out of Nebraska and into eastern South Dakota and adjacent southwestern Minnesota. Nebraska seems to have been their last major spring staging area, for sighting records diminish progressively from South Dakota northward. There is no evidence of the birds stopping in North Dakota or in the Prairie Provinces of Canada. Instead, they apparently left eastern South Dakota in mid-May, made an almost nonstop flight to the Northwest Territories, and reached the vicinity of Great Slave Lake in the latter part of May.

Almost certainly the birds began to spread out widely once they reached the arctic tundra. There is no firm evidence that they nested in Alaska, but small curlews were seen in the late 1800s at Saint Michael and Cape Lisbourne in middle to late May, and very probably bred near Point Barrow since they were reported there between May 20 and July 6 of 1882, a period encompassing the nesting season.

The few actual records of nests include a clutch of three eggs hatching at Point Lake, Mackenzie, found in mid-June of 1822, and about thirty clutches located near Fort Anderson in northern Mackenzie by R. MacFarlane in mid-June of 1863 and 1864. The nests were well hidden in open tundra, and the clutch, like that of most shorebirds, consisted of four eggs. The incubation period was probably about four weeks, like that of other curlews, and hatching was reported as early as July 12. Another four weeks was probably needed for the young birds to fledge. By the middle of August the birds were ready to begin their fall migration. The majority of the birds, presumably the adults, evidently flew eastward across the northern part of Hudson Bay, thus making a direct line for the Labrador coast. A few early-arriving birds that reached Labrador by the middle of August were probably unsuccessful breeders. There was apparently a second migration route down the west coast of Hudson Bay that reached the Atlantic coast via Ontario and the Great Lakes. A few birds also moved southward through the Great Plains, essentially retracing the spring migration route. As in the golden plover, which has a similar migration route, these may have been young birds. The few fall records for Nebraska suggest that Eskimo curlews passed through the state in October. One bird shot in Nebraska at that time had a total of thirty-one grasshoppers in its stomach, as well as numerous small berries.

By 1900, sightings of Eskimo curlews had become so rare that they

Probable Migration Corridors of the Eskimo Curlew



Joe LeMonnier

can almost be individually noted. In Nebraska the last large flock (seventy to seventy-five birds) was observed in Merrick County in April 1900, while other, smaller numbers were seen in York County in 1904 or 1905, and in Madison County in 1909 or 1910. Among the last birds shot were seven (out of a flock of eight) killed in April 1911 in Merrick County, Nebraska. In September 1913 a single bird was shot in Massachusetts. Finally, a lone bird was killed on April 17, 1915, near Norfolk, Nebraska, just a year prior to the signing of the Migratory Bird Treaty, designed to protect and control the hunting of migrating birds. So far as anyone knows, it was the last curlew to be killed in Nebraska, although a group of eight was reported seen near Hastings on April 8, 1926. In 1924 a small flock was seen near Buenos Aires, Argentina, and one was collected; the next year a single bird was shot in the same location. In 1929 one was killed in Maine. A collector for museums shot one bird in Labrador in 1926, four in 1927, and one in 1932—the year Murphy saw the four on Long Island. In 1945 two were reportedly seen in late April on Galveston Island, Texas, and another was reported in mid-July 1956 on Folly Island off the South Carolina coast, a rather unlikely time and location. In June 1946, however, there was another sighting on the South Carolina coastline, and in April 1950 a reliable observer near Rockport, Texas, reported seeing a single bird. In September 1964 a specimen was killed on Barbados. Each new record raised hopes for the species, together with fears that the very last bird had just been seen or killed.

The 1945 Galveston Island sighting had been virtually forgotten by 1959, when on March 22 two bird watchers there saw a small, strange-looking curlew feeding among a group of long-billed curlews. After tentatively identifying it as an Eskimo curlew, they returned with a professional ornithologist, G. H. Williams, who confirmed their identification.

The bird was seen by numerous other observers until April 12, and during the following year a bird was again observed in the same field. In 1961 perhaps the same bird was observed and successfully photographed, and in 1962 the exciting discovery was made that at least three and possibly four curlews were present on Galveston Island.

These Texas sightings added considerably to the hopes that a breeding population might still exist. Countering this optimism was the possibility that at least some of the birds seen may have been the Asian little curlew, a very closely related form (some ornithologists suggest it is a different race of the same species) that breeds in eastern Siberia and normally winters in Australia. But since many of the recent sightings were from the Atlantic rather than the Pacific coast, and were mostly within the traditional migratory corridors of the Eskimo curlew, these suspicions do not appear to have great merit. Nevertheless, the early sightings of possible breeding birds in western Alaska may indeed have been of the Asian species rather than of the Eskimo curlew.

There were few sightings in the period between 1965 and the present. In late August 1970, a single bird was reported by two observers at Plymouth Beach, Massachusetts. In early August 1972, two birds were observed closely on Martha's Vineyard, Massachusetts. In mid-August 1976, a pair of probable Eskimo curlews were seen flying over an area of coastal tundra along the west coast of James Bay by two experienced ornithologists, one of whom had earlier observed the species at Galveston Island. Thus, as recently as four years ago there was some evidence that this species, believed by some to be extinct by 1920, probably still existed. All told, between 1932 and 1976 there have been at least six sightings of the Eskimo curlew on the coast of Texas, seven from the Atlantic coast, and one from James Bay.

Now, after a period of limited optimism, ornithologists are again in a state of uncertainty and doubt as to the existence of this elusive bird. In spite of the ever increasing activities of bird watchers, no sightings have been reported from the Texas coast in the last decade, and the present status of this ill-fated bird is impossible to judge. Most of the persons who have summarized its sad story have come to the conclusion that uncontrolled hunting, particularly spring hunting in the Great Plains, was the single most important factor in its demise. Richard C. Banks of the U.S. National Museum has recently reviewed the history of the species' decline, and although he agrees that hunter overkill was doubtless an important factor, he suggests it may not have been the only one. Several climatic factors, including an increase in fall storms along the North Atlantic coast and possibly lowered reproductive success on arctic nesting grounds in the late 1880s during a period of unusually cool summers, could also have contributed to increased mortality and lowered reproductive rates. These speculations are interesting but inconclusive, and we are left in doubt about what, if anything, can be done to protect and preserve a species that at best seems nearly mythical and at worst may already be extinct.

There must have been a majesty to the swirling flocks of Eskimo curlews as they swept across the Great Plains or down the Labrador coast. In perpetuating their memory, one can do no better than to quote an early observer, Lucien M. Turner, who saw a flock of several hundred birds flying south along the Ungava coast of northern Labrador in September 1884.

> They flew in that peculiar manner which distinguishes the curlews from all other birds in flight, a sort of wedge shape, the sides of which were constantly swaying back and forth like a cloud of smoke wafted by the lightest zephyr. The aerial evolutions of the curlews when migrating are, perhaps, one of the most wonderful in the flight of birds. Long, dangling lines either perpendicular or horizontal, the lower parts of which whirl, rise, or twist spirally, while the apex of the flock is seemingly at rest. At other times the leader plunges downward successively followed by the remainder in most graceful undulation, becoming a dense mass then separating into a thin sheet spread wide; again re-forming into such a variety of positions that no description would suffice.

The sight of these great shifting clouds, combined with the distant sound of avian sleigh bells tinkling or wind whistling through a ship's riggings, was a phenomenon that has vanished from the American scene. ☐

**Speak German like a Diplomat!**

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign service personnel, that's who.

Now *you* can make a start on learning to speak German with the same materials used by the U.S. Department of State — the Foreign Service Institute's *Programmed Introduction to German* and *Basic Course, Continued*.

The FSI spent thousands of dollars and many years developing these materials for use by members of America's diplomatic corps. Today people in all walks of life who need to learn to speak a foreign language are turning to this outstanding audio cassette program.

The Foreign Service Institute's German Course is by far the most effective way to learn German at your convenience and at your own pace. It consists of a series of tape cassettes and accompanying textbook. You simply follow the spoken and written instructions, listening and learning. By the end of the course you'll find yourself learning and speaking entirely in German! A native German speaker, clearly recorded on the cassettes, provides an excellent model to help you develop your skills.

*This course turns your cassette player into a "teaching machine."* With its unique "programmed" learning method, you set your own pace testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes: You may order one or both courses:

☐ **Volume I. Programmed Introduction to German,** 9 cassettes, 12 hours and 647-page text, $115.

☐ **Volume II. Basic Course, Continued (More Advanced)** 8 cassettes, 8½ hours and a 333-page text, $98.

(New York State residents add appropriate sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's German course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the most convenient and most painless way to learn German, return it and we'll refund every penny you paid! Order today!

# Beetles Adorned with Horns

*If these insects were any larger, they would be fearsome*

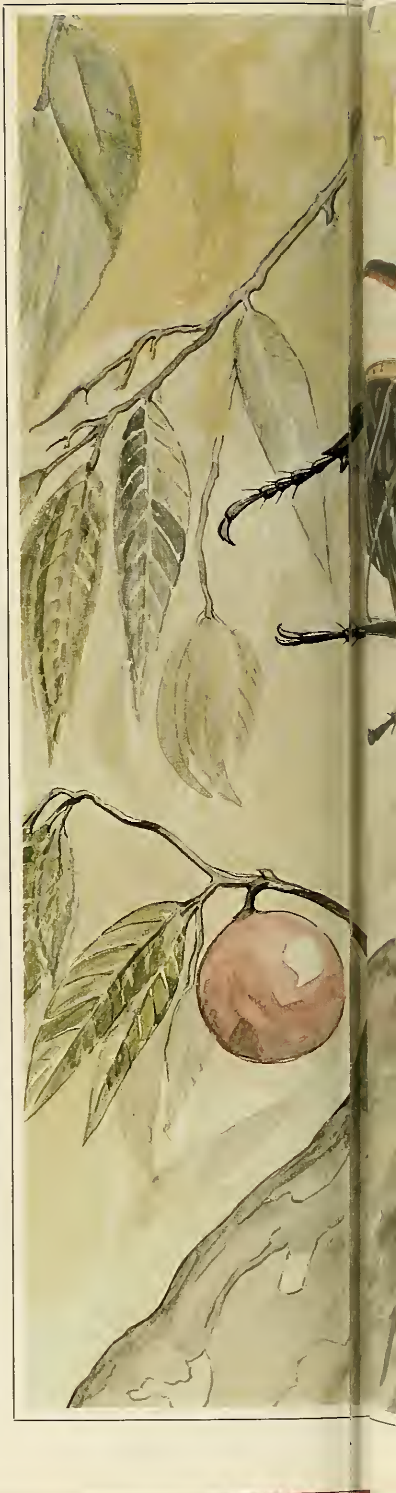
**Text and paintings by Daniel Otte**

Charles Darwin once said that if horned beetles were magnified to the size of a horse or even a dog, they would be the most imposing animals in the world. Some small boys believe that horned beetles are impressive even at their present size. In my school days in Zululand, South Africa, we dug beetles from burrows under cow dung in the summer, and the longer-horned varieties were especially prized, for they bestowed instant status. Evening preparation hours at our boarding school were made more instructive by testing the strength of beetles tethered to ink bottles, workbooks, and rulers; reputations were made and lost in matches between beetles. In Africa, where oxen are used for hauling and plowing, horned beetles are living toys and children use them to pull miniature sleds and wagons.

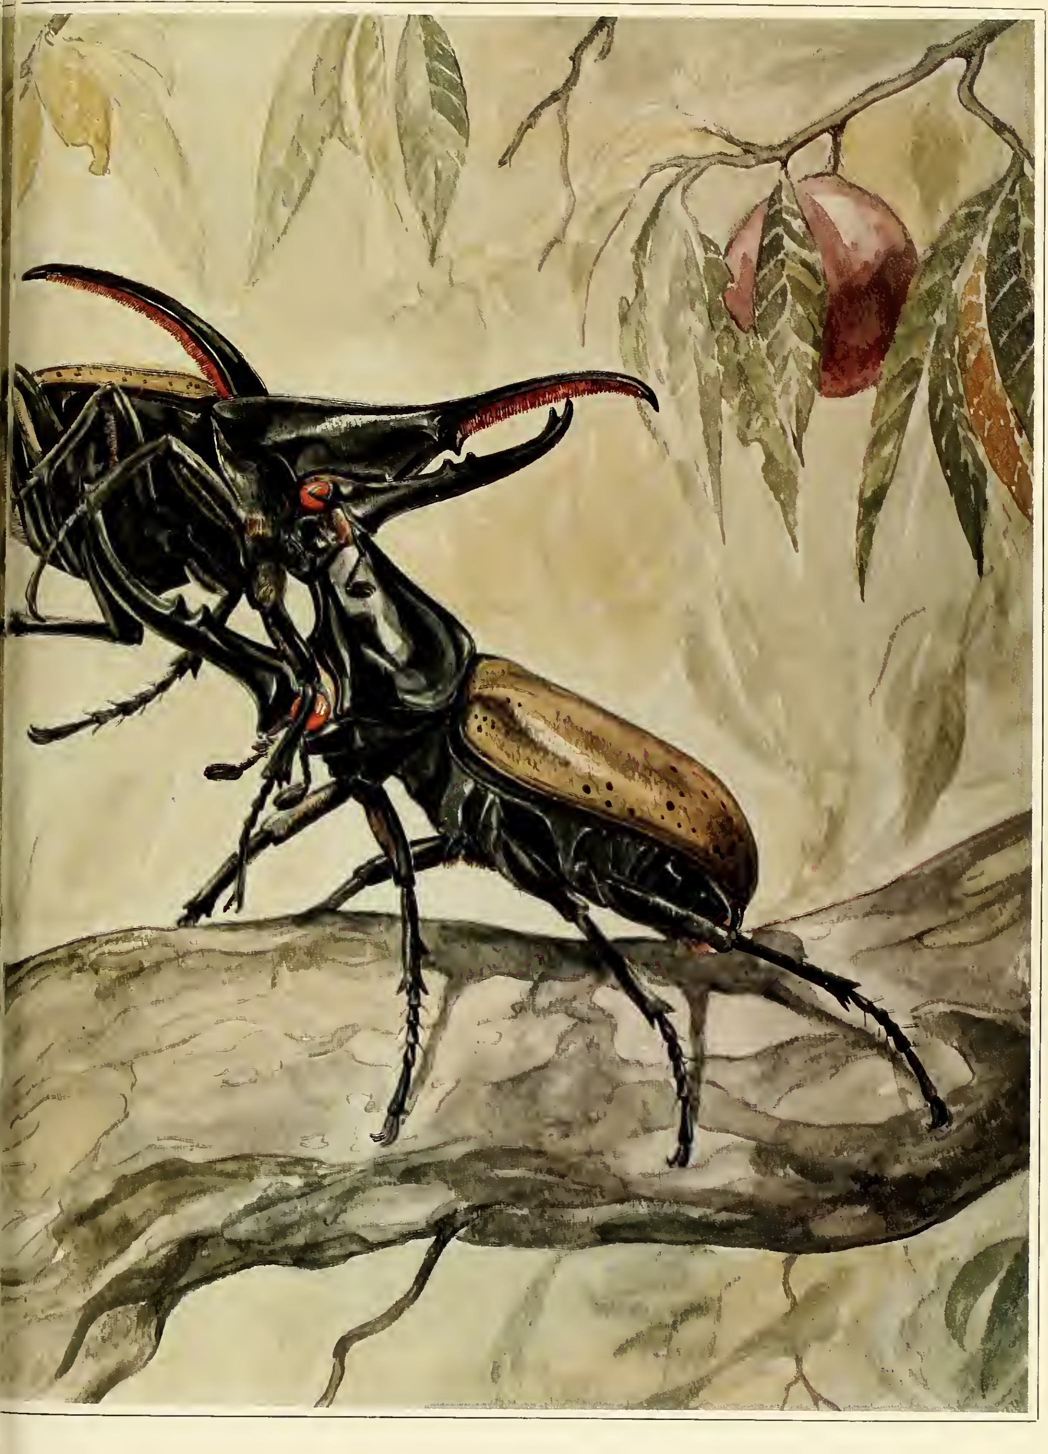
Most horned varieties belong to the Lamellicornia, a large group of beetles that includes two families: the scarabs, or chafers, and the stag beetles. Of the more than 20,000 described scarab species, most are hornless, but some scarab species develop horns that are hollow skeletal outgrowths of either the head or thorax and so are analogous to the bone and dermal outgrowths that give rise to horns in mammals and reptiles. The stag beetle family is much smaller in number of species but includes proportionately more horned varieties. Their horns are technically not horns at all but enlargements of the jaws, and they are therefore more closely analogous to mammal tusks or to enlarged bird beaks.

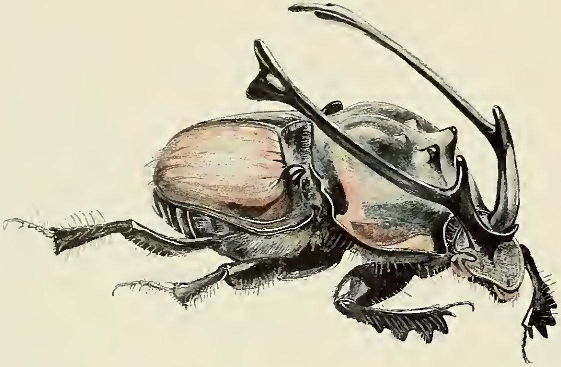
Beetle horns do not develop gradually, as in mammals, but are quickly and fully formed during the last molt to the adult stage. The final size of the horns is believed to depend on nutrition, with well-fed larvae giving rise to larger-horned adults than larvae that are poorly fed.

Early naturalists, most of them collectors, often had little time or inclination to observe the behavior of beetles in their natural habitats. Speculations on the use of horns were therefore based mainly upon examinations of pinned museum specimens or, only rarely, on observations of beetles in captivity. Some early naturalists speculated that horns were sometimes used in defense against predators, to dig burrows and bulldoze excavated material from rotting wood, as weapons in fights between males, and occasionally even to carry away a female. Darwin thought that horns might on occasion be used as ornaments to impress females, while other biologists speculated that horns could be used to lacerate stems or leaves and permit the beetles to feed on plant saps. Still another viewpoint, one held by Julian



*Two male scarab beetles battle over a favorable mating site. The victor is the one that can lift his opponent in the air and drop him to the ground.*





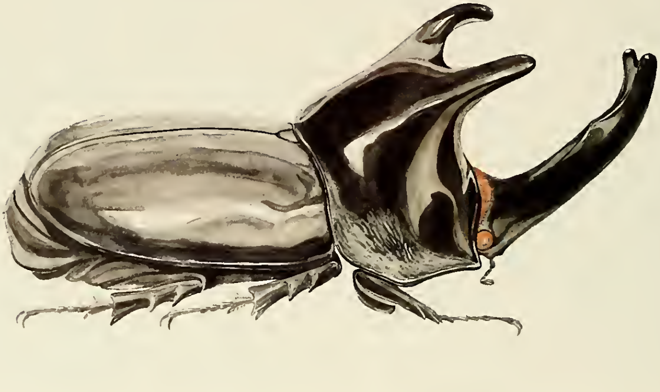
*A scarab beetle from Africa,* Onthophagus rangifer *inhabits dung heaps.*

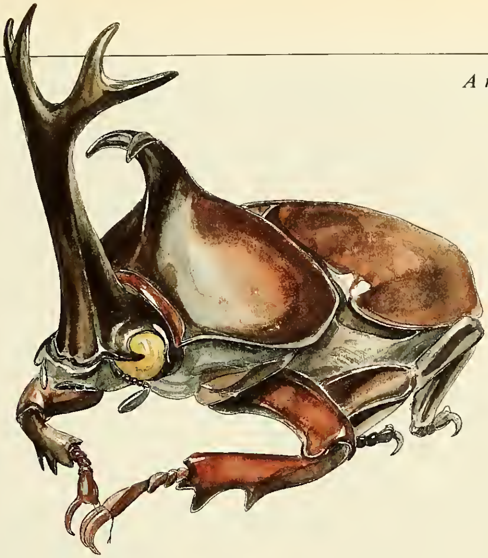
Huxley, was that horns served no function and were merely byproducts of increasing body size.

What conditions favor the evolution of horns? Gilbert Arrow, the British specialist on horned beetles, suggested that enlarged jaws are more likely to evolve in species that do not routinely use the mandibles in feeding. He reasoned that only short-lived species that feed on liquids or soft foods as adults would be free, so to speak, to evolve long mandibles. William Eberhard, who has been studying beetles in the field, has recently proposed that since many beetles live in relatively enclosed spaces, physical contests are more likely to be decided by strength in pushing matches than by speed or agility. Although the jaws were initially used in feeding and excavating, they could have been applied to biting opponents and then subsequently become enlarged.

The early stages in the development of fighting horns in scarabs are more difficult to envision. If evolutionary biologists are correct, complex anatomical features, such as horns, are acquired gradually by a series of small increments over hundreds of generations. Outgrowth horns might have begun as small bumps on the exoskeleton. For a bump to increase in size it must give its bearer some advantage over other members of the population. But could a small bump have been used as a weapon? Intuition tells one that the structure would have to reach

Megacerus jason *is a scarab with formidable pinching ability.*



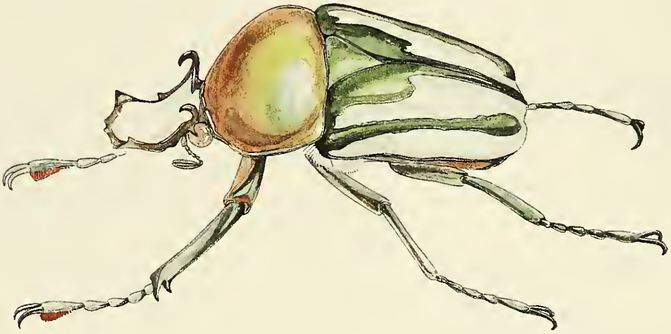


*A native of Japan,* Allomyrina dichotomus *sports horns that resemble deer antlers.*

some critical size before it could become effective (just as an adjustable wrench must be opened or closed to a critical point to be effective on a nut). One can surmise that outgrowth horns of scarabs evolved to an effective size for fighting only indirectly—perhaps the projections, or ridges, were initially used to move debris or dung, and that in such situations even the smallest changes in the exoskeleton could have made a difference to the animals bearing them and so could be modified by natural selection. Once they reached a certain critical size they could begin to act as weapons and be improved by a new set of selection pressures.

Among the horned beetles the mode of breeding seems to influence how similar the two sexes are to one another. In promiscuous species, those in which males mate with several females and take no part in assisting the female in rearing offspring, body size and horn differences between the sexes are pronounced. In monogamous species, in which the male mates with and assists a single female, the two sexes are often nearly identical in size and appearance. The few differences between monogamous mates are usually behavioral, associated with a well-defined division of labor. In the stag beetle *Sinodendron cylindricum,* for example, the mandibles do not differ in size or shape. The two sexes collaborate in preparing a burrow and provisioning it with food for the young.

Ranzania splendens *is a horned scarab that lives on foilage. Its horns can be used to scoop opponents off tree perches.*

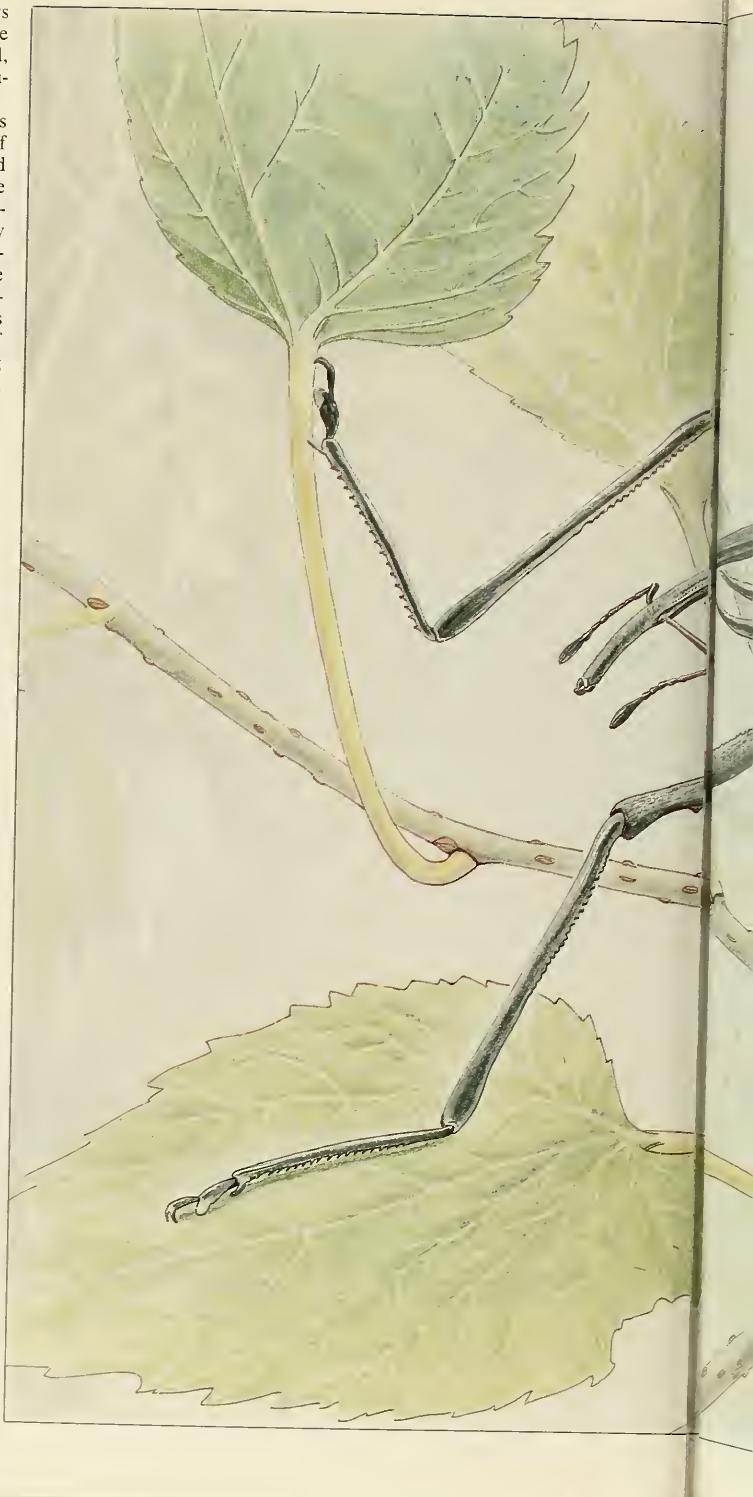


As a rule the female digs the burrows and prepares brood niches while the male travels backward and forward, sweeping and removing the accumulating debris.

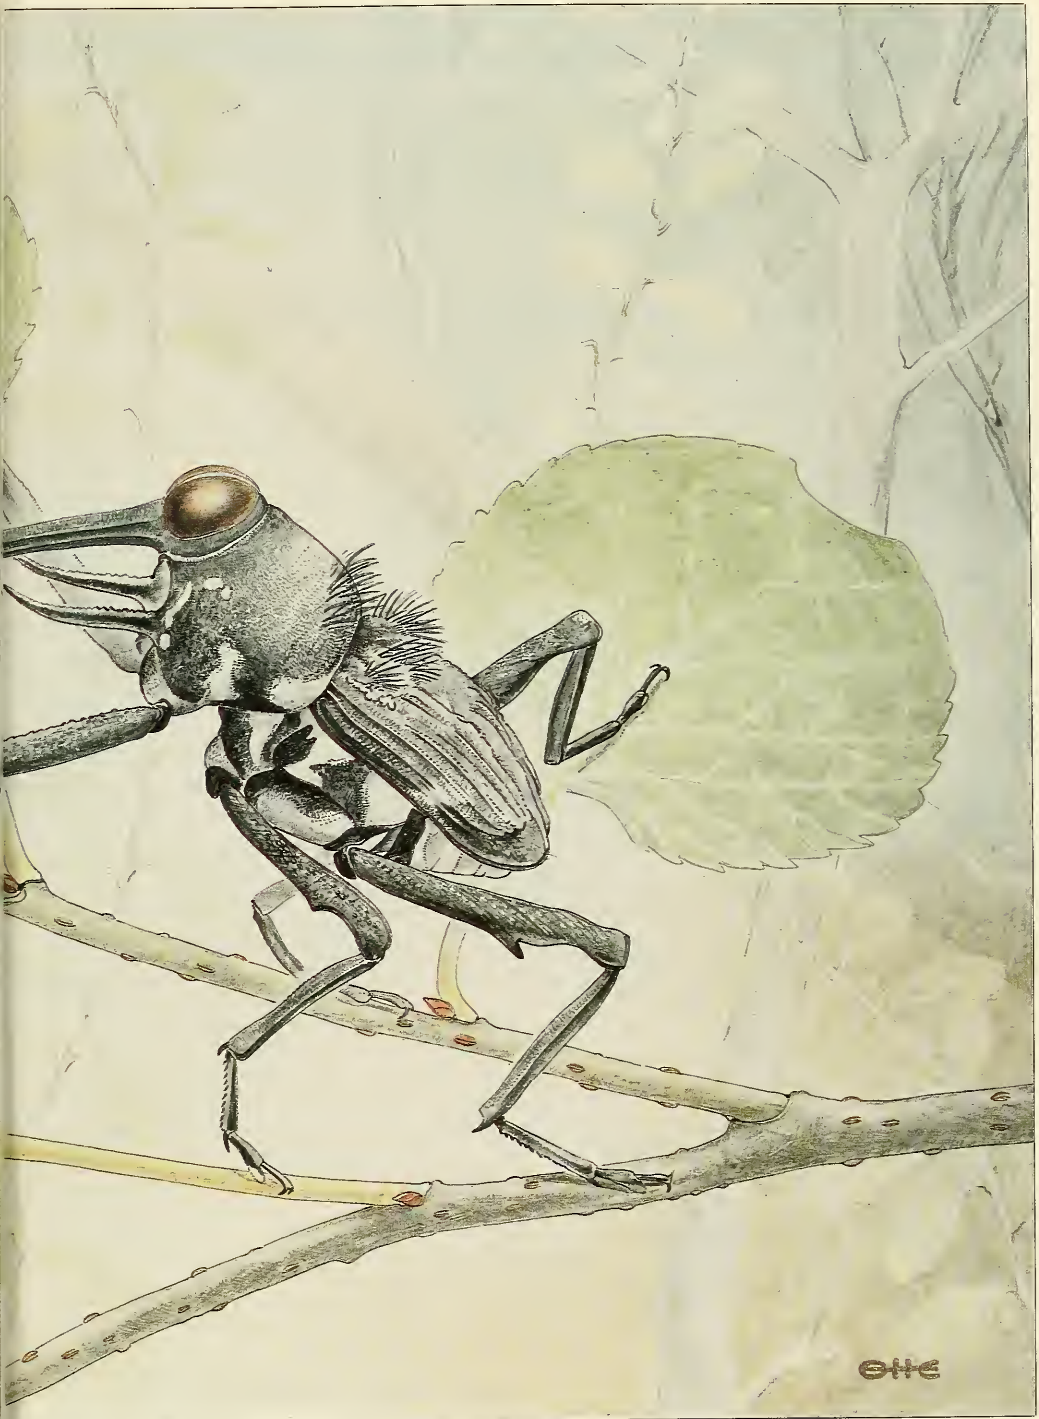
One commonly expressed notion is that beetle horns are the product of sexual selection, the force conceived by Charles Darwin to account for the striking structural and behavioral differences between the sexes of many species. As presently understood, sexual selection is usually viewed as the selective influence exerted by members of the same sex or by members of the opposite sex in the context of reproduction. Males can exert a strong selection pressure on their own sex if inherited differences cause some to win and others to lose in the competition to reproduce. Females can intensify this pressure by mating only with males victorious in battle or by favoring the most brightly colored or largest males available to them.

Females in at least one species of beetle seem to have a more than passing interest in the outcome of battles raging on their behalf. Darwin described how females of the stag beetle *Lethrus cephalotes* seemingly force males into combat and mate with the victor. "The two sexes inhabit the same burrow, and the male has larger mandibles than the female. If, during the breeding season, a strange male attempts to enter the burrow, he is attacked; the female does not remain passive, but closes the mouth of the burrow and encourages her mate by continuously pushing him on from behind; and the battle lasts until the intruder is killed or runs away." Mating with winners may have certain advantages. A female does not need the ability to judge the quality of a mate if males of higher quality tend to win, which they do, nor does she risk being deceived by male advertisement or propaganda.

Darwin knew that beetles occasionally used their horns in combat, but he suggested that the more spectacular varieties were perhaps ornamen-



*The two tusks behind the long snout and the spines on the hind legs suggest that fighting occurs among males of this species of* Mecopus. *This beetle is native to the Solomon Islands.*



OHE

tal and used principally to excite females. His judgment on the pinching powers of beetles was based, so far as we can tell, on his experiments with *Chiasognathus grantii*, a huge-jawed beetle from Chile. By placing his thumb between its horns, Darwin discovered that *C. grantii* could not hurt him. But *C. grantii* and its close relatives happen to be unusual among stag beetles in having exceptionally narrow heads, a feature that makes it difficult to exert much lateral pressure. Had Darwin experimented with a broad-headed species he might well have ended up with a punctured thumb and a different theory.

As the habits of more species are studied, the uses of horns are becoming clearer. Fighting has been seen in many species and *C. grantii* have been seen tearing one another apart. W. D. Hamilton, who has observed fighting in *C. grantii*, believes this species fights mainly in trees, where females may be attracted to sap flows or flowers; males perhaps wait here for females and fight among themselves to be the first to mate with any female that arrives. During these fights males try to lift one another into the air, and battles are won by the male who lifts his opponent and drops him to the ground. Not surprisingly, males with small horns lose to larger males.

Larger males within a beetle species have relatively larger horns than small males, and comparisons among species indicate that the largest horns, relative to body size, are found in the largest species—a relationship that is also known to occur among some lineages of deer. William Beebe saw this phenomenon in some South American beetles and called the larger-bodied, big-horned types *majors* and the smaller-bodied, smaller-horned individuals *minors*. When William Eberhard measured a large number of males of the scarab *Podischnus agenor* he found that horns fall into two distinct size classes. In species of stag beetles in which we have measured large numbers of males, large males and small males are revealed to be the ends of a continuous size distribution.

Why the larger individuals of a species possess relatively larger horns than smaller individuals is an unsolved problem. One hypothesis relates to the allocation of resources during development. Males that are relatively energy starved during maturation might be expected to avoid expenditures on horn development if a certain minimal horn or body size must be attained for them to be effective in fighting. Such males might rely instead on high dispersibility and increased longevity to augment their chances of finding and mating with females. But males with access to abundant resources during the larval stages might, after attaining the optimal body size, put all available energy into horns and their supportive structures. According to this hypothesis horns are a luxury that only males with access to large quantities of food can afford.

Male beetles employ different reproductive strategies. If mating investment is the energy that a male must expend to maximize the number of matings he achieves, at least two major evolutionary modes of investment are apparent: a male can emphasize the production of structures, such as horns and muscles, that give him strength and protect him from possible injury; or he can increase the chances of encountering unmated females by emerging first to the adult stage or by increasing his awareness of females and his quickness in reaching them. William Beebe observed how both modes may exist within a species of beetle. When he placed a small male of *Dynastes hercules* into a chamber with five large males and four females, the small male showed far greater vitality than any large one, mating with all the females in turn and several times in succession with two of them, while the larger beetles mated with only one or two. In combat the small male could not win; although he fought vigorously, he was invariably carried off the field held high in the air.

Fighting between insects is often not harmful because the contestants only exhibit behavioral displays that do no damage. Geoffrey Parker has argued that it is important for animals to know their relative strengths, and that ritualized fighting is a way for combatants to estimate their strength. Small or weak males may break off an encounter with larger or stronger males when the probability of a successful combat is low. After the initial bouts, large males may be encouraged to continue the fight because the resources can be gained with little extra effort. If the combatants can gauge their strengths in initial encounters, weaker individuals should give up and fights should not escalate.

In higher animals, strength seems to be determined visually and can be done at a distance—the contestants evaluate one another on the basis of body size and horn length, and fights seem to occur only among closely matched rivals. When animals merely estimate the prowess of rivals, the system is open to exploitation by bluffing. When males actually grapple with one another, the contestants can directly determine one another's strength. But when the assessment involves distance signaling, all a male needs to do is convince his rival that he is stronger, which he can do by posturing and through other forms of propaganda. Sir Ronald Fisher believed that males should, as a consequence, become less and less deceived by propaganda and be persuaded only by signals that indicate a genuine prowess.

Propaganda seems to be more prevalent in species that advertise their prowess through distance signaling than in species that must prove their ability. There is no evidence for the existence of power advertisements or propaganda in insects. They are probably forced to lead less deceitful lives because of their visual and sensory shortcomings. The assessment of strength requires contact, so they are more likely to determine real strength than are mammalian contestants who engage in much visual estimating. Because it is difficult for insects to signal their strength at a distance, fights between grossly mismatched males might be more common.

When horned beetles are observed more carefully under both natural and controlled conditions, we should learn more about how horns are used and which selection pressures directed their evolution. It should be especially interesting to know if countervailing selection pressures will result in different modes of competition among the members of a single population and to discover which differences within a species are due to genetic factors and which attributable mainly to developmental conditions. ☐

*Having lifted his opponent, a longer-horned male is in position to throw the smaller-horned beetle to the ground. This species of stag beetle,* Chiasognathus grantii, *is the one Darwin encountered in Chile.*

# Warriors of Maasailand

*Although a lion could run faster, we could run farther*

**by Tepilit Ole Saitoti**
**photographs by Carol Beckwith**

When circumcised Maasai youths enter warriorhood, at about sixteen years of age, they let their hair grow long and spend much time in grooming it. Everything they wear must be new, to symbolize a new life. They replace their old attire with togas dyed with red ocher. They also cover their bodies from head to toe with the same red ocher. Their parents give the warriors new long spears, and their mothers and girlfriends make all new beaded ornaments for them.

The youths begin to experience a freedom that they never had before as mere boys. They can now socialize with girls and have sex. They are free to roam Maasailand without asking their parents' permission. They have more control over their destiny and some degree of decision-making power. They can shake hands with other men as equals, instead of bending their heads in the respectful greeting of a child. And they attain the high degree of confidence that is known and enjoyed only by Maasai warriors after total manhood.

Young are the warriors, and we feed them the best of our meat. Healthy, they will protect our herds from enemies and famine. And they will stop all the foes of our people from encroaching upon us.

These words, sung by senior warriors to their younger comrades, express something of the significance and the almost magical powers attributed to the title *ilmoran* ("warriors") in Maasailand. Whenever there is

*Resplendent in ostrich-feather headdresses and special cloaks, warriors perform the* Enkipaata *dance, part of* Eunoto, *the ceremony in which they graduate to elderhood. During the dance, the warriors may fall to their knees and wave their headdresses in unison.*

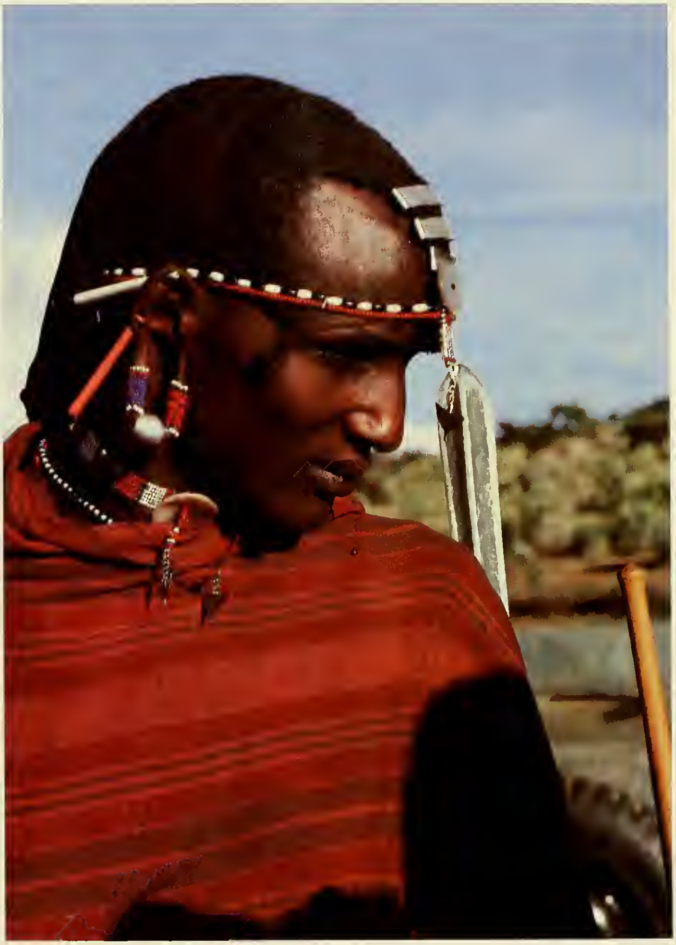
work requiring strength or courage people will ask, "Are there no warriors around today?" Warriors are needed both for simple tasks—capturing a cow to be slaughtered for a ceremony and decorating it with bells, wrestling with one to be branded—and for dangerous ones—protecting the herd from lions or subduing a crazy rhino charging through the kraal. Maasai warriors in their prime seldom fall short in the performance of their duties. When praised, they will modestly answer, "All we did is what Maasai warriors are supposed to do."

I remember from my own experience as a warrior how self-confidence takes over the whole being, along with pride and a feeling of ease, as if you yourself and all those around you were thinking, "Everything will be all right as long as the warriors are here." We were supposed to be brave, brilliant, great lovers, fearless, athletic, arrogant, wise, and above all, concerned with the well-being of our comrades and of the Maasai community as a whole. We realized that we were totally trusted by our community for protection, and we tried to live up to their expectations. If, for example, a lion would roar near our kraal at night, we would be so insulted at his boldness. All we would wish for was daybreak so that we might go in search of him, hunt him, and teach him a lesson: that we warriors, and not he, reign supreme. We used to say that until a lion could roast his meat, that is, stop eating raw meat, he would never be able to challenge us. And we used to boast that although a lion could run faster than we could, we could run farther.

Maasai warriors are so fearless that a German writer by the name of Karl Peters observed, at the turn of the century, "The only thing that would make an impression on these wild sons of the steppe was a bullet . . . and then only when employed in emphatic relation to their own bodies." Warriors are reputed to be afraid of nothing short of Almighty God; even foreigners do not scare them. Often they do not bother to distinguish persons dressed in foreign clothes from each other, be they white or black. They sum up foreigners with the word *ilmeek*, meaning "aliens," or *iloridaa enjekat*, meaning "those who confine their farts." This last term refers to the nature of European clothes, which

do not allow the wind to blow away any unwanted odors, as does the Maasai toga.

Besides this most important quality of bravery, Maasai warriors have many other virtues. One of these is the strong comradeship they feel for each other. Maasai warriors share practically everything, from food to women. According to tradition, a warrior must never eat alone. This was first made a law in order to ensure that every warrior, even one from the poorest family, would have enough to eat. And even today, warriors roam Maasailand always in groups, never alone, for this reason. There are even certain sections that forbid a warrior to drink milk from his own cattle, in an attempt to encourage sharing rather than selfish monopoly.



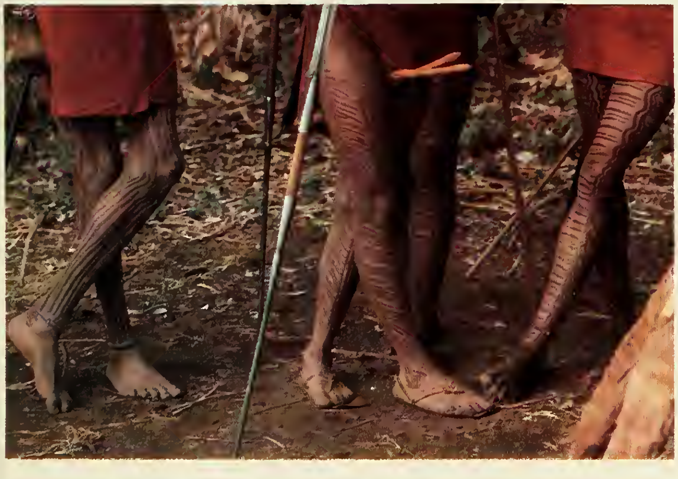
*Above: This warrior, his spear point-up by his side, has plaited his hair and decorated himself with metal ornaments, colorful beadwork, and disks made from crocodile eggshells. Girlfriends fashion beadwork ornaments for the warriors. Left: Maasai houses, arranged in a rough circle called an* engang, *are made of woven tree branches patched with leaves and grass and plastered with dung. Protection from the heat of the day is provided by large acacia trees; the species shown here is nicknamed "the shade tree."*

The physical appearance of the Maasai warrior expresses all the qualities that the Maasai, and even many foreigners, consider desirable. This is particularly true when the warriors are seen in full war gear on their way to a cattle raid or to retrieve stolen cattle. Like finely crafted bronze statues, the warriors appear in full regalia with headdresses of gleaming black ostrich feathers or lions' manes, elaborately patterned shields of buffalo hides, and spears glistening in the sun. They are both admirable and awe-inspiring. Today, restricted by the ban on hunting wild animals, the Maasai find it harder and harder to obtain buffalo hides for their shields and lions' manes for their headdresses.

Their physical beauty and the decoration of their bodies are important to Maasai warriors in times of peace as well. Anxious to attract girls, they spend hours decorating themselves with ocher and plaiting their hair. They first grind the ocher, then mix it with fat or water. After this mixture is applied to the legs and while it is still wet, decorative patterns are drawn with the fingertips or a stick. Warriors braid their hair into long plaits, often twisting in strands of wool to create greater length, and then dye it red with a mixture of ocher and fat. They adorn their earlobes, necks, arms, waists, and ankles with the beaded ornaments made by their female suitors.

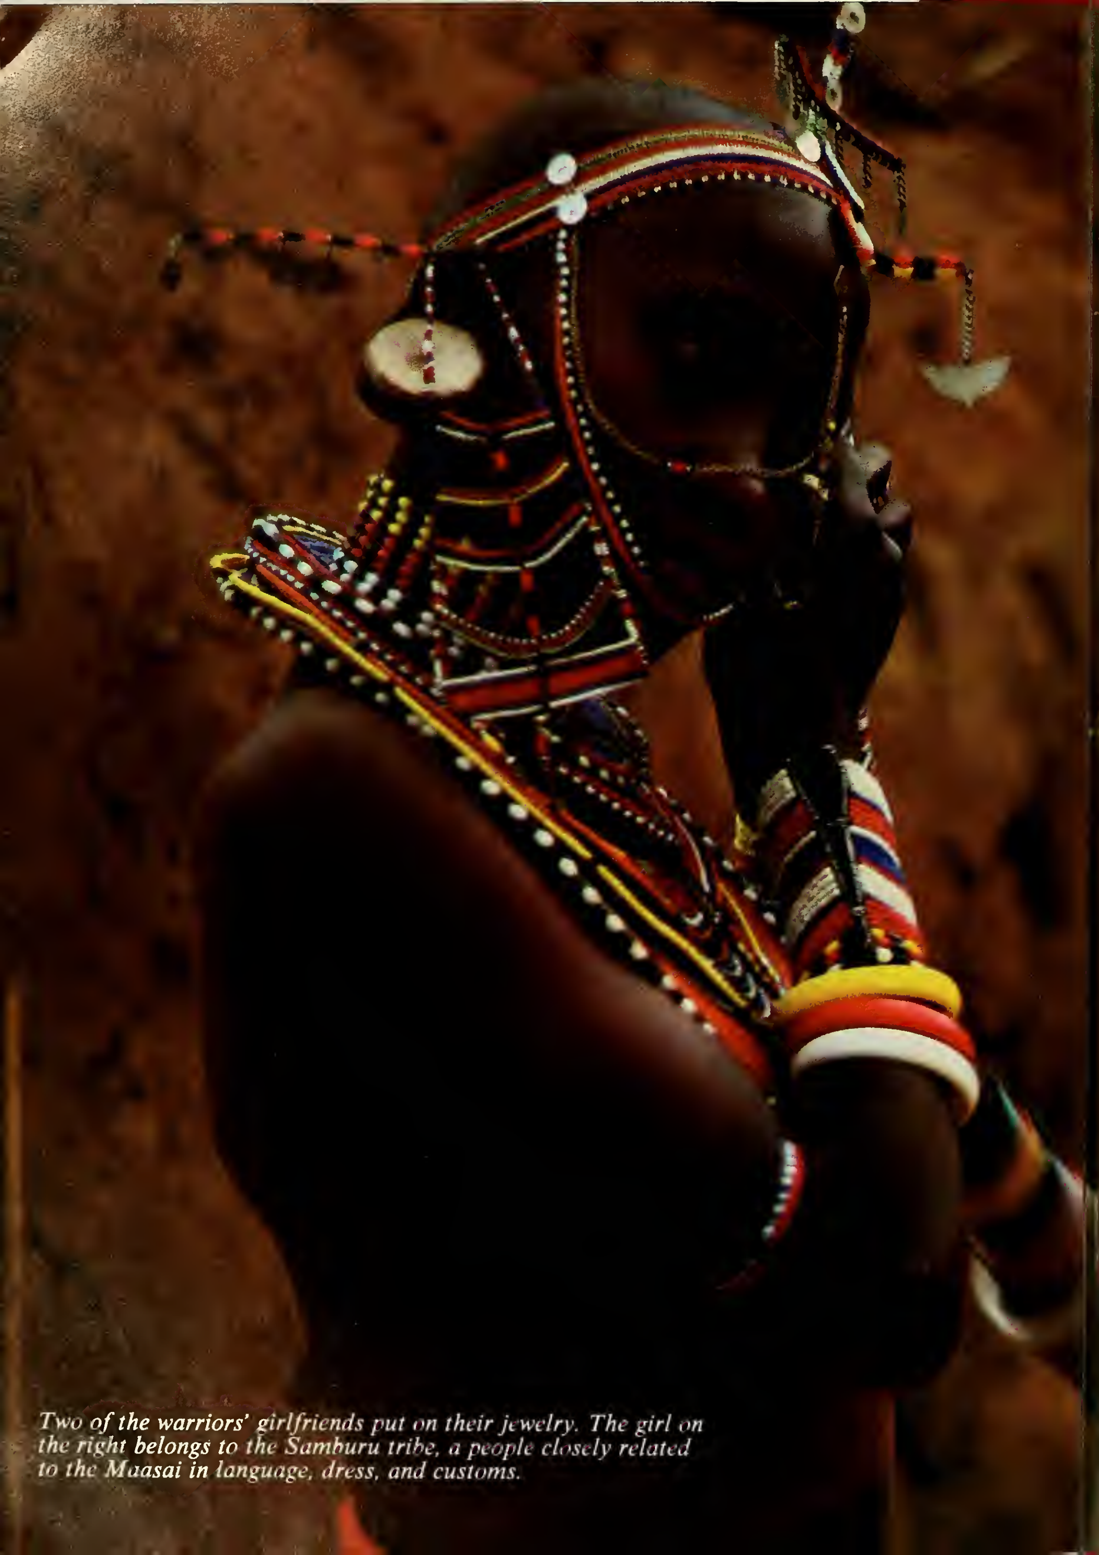
The ever present spear of a Maasai warrior is a most precious possession. A traveler in Maasailand often sees the lightning flash of a Maasai spearpoint gleaming in the distance before the silhouetted body of a warrior appears. The warriors develop a worshipful trust in their weapons, and certain braves will never flee from an attack as long as their spears are still in their hands, for fleeing would be like betraying their weapons. The warrior anoints his spear with animal fat and polishes it often to prevent rusting. All day long, the spear is held in the warrior's hand or thrust, point-up, into the ground by his side. It would be considered a serious insult to a Maasai warrior if anyone were to insert his spearpoint into the ground. At night it is stored inside by his girlfriends. Not used for fighting alone, the spears are sometimes decorated to symbolize peace. Pure black ostrich feathers are attached to the tip of the spear with

*Left: In jumping dances, Maasai men often compete for the highest leap, but the rhythmic jumping always appears effortless. The men, who participate in these dances throughout their lives, stand in a circle and sing with a strong, breathy beat while one or two of them jump in the center of the circle. They accentuate the peak of their leaps by trembling their shoulders. Below: During warriorhood, Maasai males periodically go off to a feasting camp, called* olpul, *to gain strength, share wisdom and lore, and prepare for lion hunts and cattle raids. When they return, they play among themselves and with their girlfriends, with whom they gather to sing and dance at the end of the day. Bottom: In addition to styling their hair, warriors decorate their legs, using their fingers or sticks to paint patterns in the wet ocher or chalk with which they cover their legs.*



a string of beads, forming a round crown. A piece of black ebony may be inserted into the spear shaft to indicate a warrior's seniority, while a section of pale wood indicates his junior status.

The activities of Maasai warriors are many. Within their family communities, they are very helpful, performing such tasks as building thorn fences to protect the herds, clearing sand from wells, and watering cattle during the harsh dry season. Warriors tend the cattle only if they have no younger brothers to help them. When not working, the warriors group together to sing or play. A common game involves throwing wild sisal stalks or the round yellow fruits known as "Sodom apples" at each other and fending off the blows with their



*Two of the warriors' girlfriends put on their jewelry. The girl on the right belongs to the Samburu tribe, a people closely related to the Maasai in language, dress, and customs.*

shields. This game gives them much practice in using their shields effectively. Sometimes they chase their beautiful girlfriends, teasing them with branches, or get into mock fights with them.

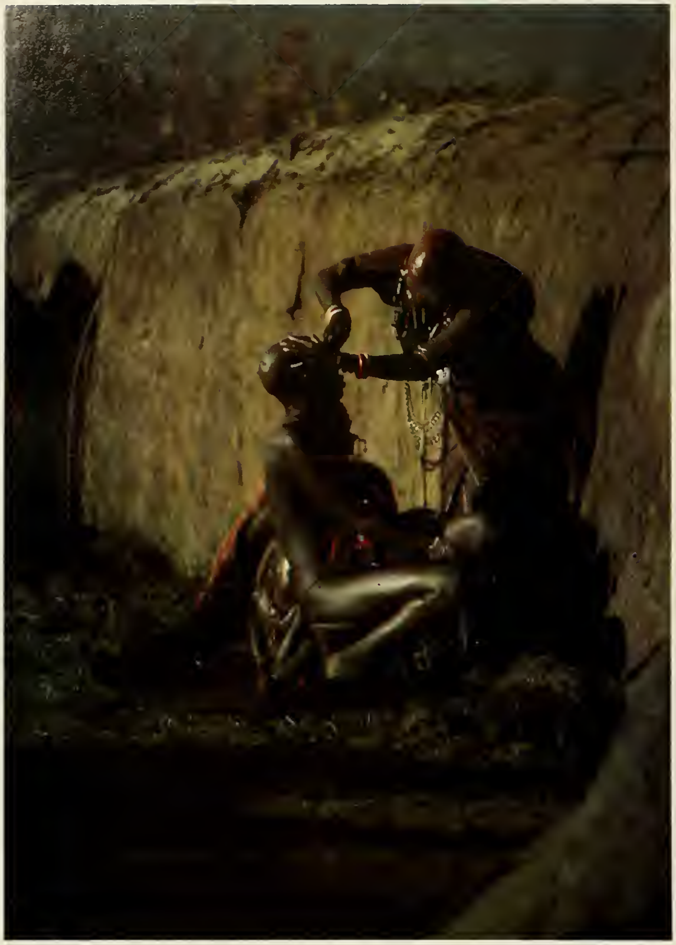
Another activity of the warrior is called *enkitoongiwong*. This involves a vigilant exploration of their surroundings to obtain news and defend against danger. On certain occasions when warriors are happy, such as during the rainy season, they hunt lions as a demonstration of bravery and courage. This formal lion hunt is called *alamaiyo*.

Although the government has forbidden them, cattle raids and lion hunts are still held, on a small scale, by Maasai warriors. Maasailand is so immense that it is hard for the government to patrol it properly. Before it was forbidden by the colonial governments in the early 1900s, cattle raiding was a popular and useful warrior's occupation. A cattle people who believe that all the cattle on earth belong to them, the Maasai would go on cattle raids to retrieve herds from other tribes, which they believe must have been taken from them long ago. First, scouts would be sent out to find large non-Maasai herds suitable for raiding. They would return with cattle dung as proof of their success, and the necessary number of warriors, sometimes as many as one thousand, would be mobilized. In recent days, cattle raiding is no longer a formal, colorful public display, but is instead pure theft. Those few diehard warriors who still raid must be very discreet, for if they were arrested by the government authorities they would be severely punished.

Because of their sacred love of cattle, however, the Maasai will always be enemies of any outsider, African or European, who keeps cattle. The warriors are still a Maasai standing army ready to defend their land and cattle from enemy attack. Tall, handsome, and fearless, they will fight to the end. It would be in proud pursuit of cattle that all Maasai warriors would wish to die if death must come.

The plains and rolling hills of their broad land must have witnessed, many a time, Maasai warriors in action. Their weapons are treacherous—the sharp sword with a double edge used to hit and slash; the short club with a round head used for beating or

*Warriors, with their girlfriends and mothers, participate in song and dance*



*As they prepare to embark on the new life of elderhood, warriors must part with their long hair. Mothers who have not indulged in sexual relations with warriors of their sons' generation have the honor of shaving their sons' hair, a highly emotional and sad part of* Eunoto, *above. With their shaved heads freshly ochered, right, warriors come together to sing and dance in a special enclosure made by forty-nine skin-covered houses. Within this enclosure is the* Osingira, *or ritual house.*

throwing at the enemy; the stick with sharp points at each end, which is hurled at the enemy; and, indeed, the spear with its invisible thrust, the warrior's best friend. One looking at Maasai dress can observe certain resemblances to the attire of the ancient Romans, who once occupied North Africa. The Maasai sword resembles the short Roman fighting sword; the warriors' hairdo follows the shape of the Roman helmet; and the toga and sandals are similar in style to those of the Romans.

Warriors have various traditional war formations for approaching the enemy, depending on whether he is positioned in open plain, forest, or bush country. If the enemy is in open country, for instance, they close in, carrying enormous buffalo shields,

and create a wall of warriors in an eagle-wing formation. The bravest warriors form a spearhead in the center to split and penetrate to the heart of the enemy line. Others will be positioned on the sidelines to give support to the spearhead. Behind the spearhead there is the rear guard, which comes to the rescue in case the front is overpowered. (The last major Maasai war was fought by the Tanzanian Maasai against the Bantu tribes around Lake Victoria during World War I. The Maasai were aware that the Germans and British rulers of East Africa were preoccupied with the war and were not in a position to stop intertribal warfare. They were most successful in their main purpose, which was to gain cattle to build up their decimated herds.)

While Maasai warriors are famous for being unbeatable during battle, they also know how to accept defeat. They will always say, "The war will be won by either side, ours or theirs," as the following song illustrates:

God, bird of prey,
Accompany me on the raid,
Because if I don't get killed,
I will kill, and you will always have
One of us to feed upon.

When the pressure from the generation below them becomes great enough, warriors are forced to graduate into elderhood to make room for the new generation. The most important ceremony involved in this transition is called *Eunoto*, literally, "planting." In one of the most sentimental moments of the ceremony, the mother of each warrior shaves off her son's long plaited hair, softening it with a mixture of milk and water.

Often the warriors will cry or go into an emotional frenzy, shaking all over and foaming at the mouth, desolate at the loss of the beautiful long hair that has been a proud possession during the highest period of their manhood. They hate the idea of their approaching elderhood, which marks the coming of old age and the end of warrior comradeship. "Now that you are an elder drop your weapons and use your head and wisdom instead." "Master the art of the tongue and wisdom of mind." "Family responsibility rests on your shoulders." Such words echo in the mind of the Maasai as he embarks on the new life of elderhood. □

# The World's Greatest Lakes

*Lake Baikal (shown here) and Lake Superior have similar wonders, beauties . . . and problems*

**by Wayland R. Swain**

It is difficult, if not impossible, to describe anything associated with Siberia without using superlatives. Even its name reflects its size. "Siberia" was derived from the word Сибир (Sibir'), which, in the language of the ancient Buryats who dwelled in the area, means "the sleeping giant."

Precise measurements of the sleeping giant's domain vary, depending on the inclusion or exclusion of certain eastern provinces, but conservative estimates suggest this vast landmass is in excess of four million square miles. In the heart of this immense landscape, two-thirds of the way from the Urals to the Pacific Ocean, lies the oldest and largest body of fresh water in the world, the earthquake-riven basin known as Baikal. Lake Baikal has a special place in the hearts of Russians. Called variously Sacred Baikal, the Sacred Sea, or the Glorious Sea, it is thought of with a reverence that outshines any such widespread feeling about the Great Lakes in this country. It was, in fact, our Great Lakes that brought me to Russia.

I traveled, with ten other Great Lakes scientists, aquatic toxicologists, and administrative personnel to the Soviet Union under the auspices of the U.S.–U.S.S.R. Joint Agreement on Environmental Protection. We went to attend a scientific symposium and to compare Baikal, this "elder of the tribe" among the world's freshwater bodies, with our own North American Great Lakes, particularly, the appar-

Paolo Koch, Photo Researchers

ent relationship with Lake Superior. There were differences, to be sure, but in many ways, they only emphasized the similarities.

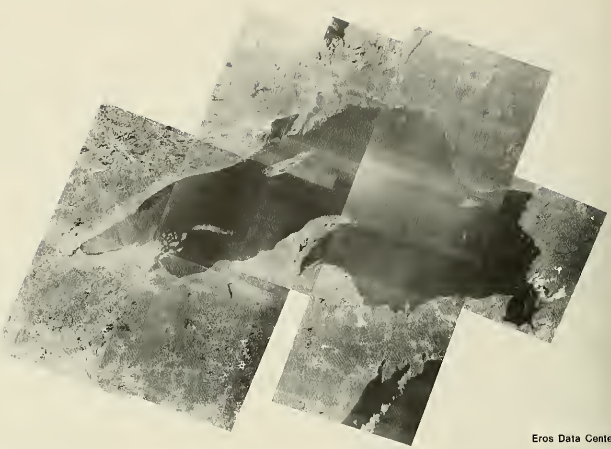
In the Superior-Quetico Wilderness bordering Lake Superior, spring wildflowers erupt through the thin soil layer in June. A month later, the process is repeated on the shores of Lake Baikal. Lilacs blossom, migratory waterfowl return, and gentle spring rains fall. As I knelt on the shoreline to take samples of the water, 20,000 miles vanished, and it was nearly impossible to separate Baikal from Superior by outward appearances alone. The shorelines of both lakes consist of pebble-strewn beaches flanked by craggy rock outcroppings and escarpments that rise to impressive heights and provide a springboard for numerous rivulets and miniature waterfalls, which cascade into the basin. Astonishing in clarity, bone-chilling in temperature, and of a hue and intensity of blue to beguile poets, the water in Baikal and Superior appear to have been derived from the same source.

These lakes are of such proportions that, like Siberia, they can only be spoken of in superlatives. Superior, the largest lake in the world by surface area (31,820 square miles) is fed by more than 200 tributary streams and is drained by but a single outflow, the Saint Mary's River. Baikal, the world's largest lake by volume (5,500 cubic miles) is fed by 336 tributaries, and also gives rise to a single outlet, the mighty Angara River.

Nearly 400 miles in surface length, Baikal has some 1,300 miles of shoreline. Superior, while nearly the same surface length, has 1,800 miles of shore. But, while the volume of Superior is taken to be 3,000 cubic miles, Baikal holds 5,500 cubic miles of water, almost enough to fill the basins of all five of the North American Great Lakes (slightly more than 6,150 cubic miles). Superior's deepest section is of the order of 1,330 feet, and Baikal's maximum depth is now given as 5,314 feet, more than three times that of Superior. Freshwater more than a mile deep is impressive, and even more so when one considers that an additional four miles of sediments have accumulated in the bottom of the Baikal trench as a result of its 20 to 30 million years of existence. Superior is but a youth by comparison, only about 10,000 years old.

The way the basins of the respective bodies of water were created accounts, in part, for both their differences and similarities. The rocky fault that holds the waters of Baikal resulted from a massive shifting of the earth's crust in that region. A monumental series of earthquakes is thought to have been responsible for creating the great rift that forms the present lake basin. Current theory suggests the lake may well be the forerunner of a new ocean that will divide the northern and southern portions of the Asian subcontinent into two distinct landmasses.

It could be said that Baikal is still in the process of creation, even after millions of years. As recently as 1861, a massive earthquake and a series of aftershocks of catastrophic proportions caused a seventy-square-mile portion of the eastern shoreline to fracture and sink, drowning some 1,300 inhabitants of the region, and creating a new arm of the lake called Proval Bay.



Eros Data Center

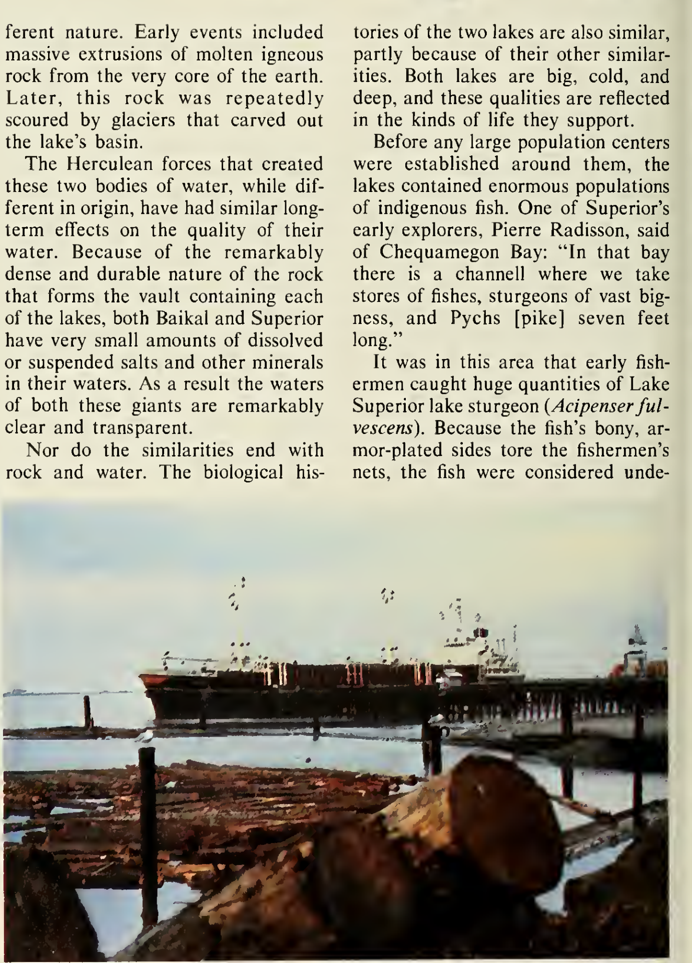
The sequence of events that created Lake Superior was of an entirely different nature. Early events included massive extrusions of molten igneous rock from the very core of the earth. Later, this rock was repeatedly scoured by glaciers that carved out the lake's basin.

The Herculean forces that created these two bodies of water, while different in origin, have had similar long-term effects on the quality of their water. Because of the remarkably dense and durable nature of the rock that forms the vault containing each of the lakes, both Baikal and Superior have very small amounts of dissolved or suspended salts and other minerals in their waters. As a result the waters of both these giants are remarkably clear and transparent.

Nor do the similarities end with rock and water. The biological histories of the two lakes are also similar, partly because of their other similarities. Both lakes are big, cold, and deep, and these qualities are reflected in the kinds of life they support.

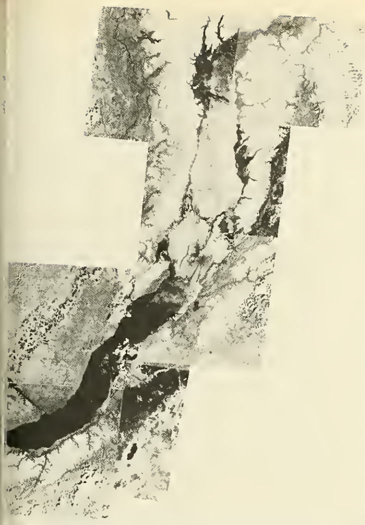
Before any large population centers were established around them, the lakes contained enormous populations of indigenous fish. One of Superior's early explorers, Pierre Radisson, said of Chequamegon Bay: "In that bay there is a channell where we take stores of fishes, sturgeons of vast bigness, and Pychs [pike] seven feet long."

It was in this area that early fishermen caught huge quantities of Lake Superior lake sturgeon (*Acipenser fulvescens*). Because the fish's bony, armor-plated sides tore the fishermen's nets, the fish were considered unde-



*Logs from the shores of Lake Superior*

Jim Brendenburg



*USGS Landsat composite photographs of Lake Superior, left, and Lake Baikal, right, shown to scale*

sirable and were stacked, like cordwood, in great piles on the beach and burned. Today, in Superior, this species is virtually extinct.

In Baikal, overfishing for what was once the most valuable food fish of the lake, the Baikal sturgeon (*A. baeri baicalensis*), reduced the population so drastically that for a time, recovery was not thought possible. For some years, fishing for the Baikal sturgeon has been strictly forbidden. Consequently, the sturgeon population is now steadily growing and one day may again reach its original proportions. Two specific characteristics of the adult fish were responsible for its decline in Baikal. The fish, which can grow to a length of seven to ten feet and weigh more than 500 pounds, not only has delicious flesh but, in season, also yields quantities of greatly valued black caviar.

Both lakes have fishy oddities of less dramatic proportions. Baikal is noted for the Baikal omul, *Coregonus autumnalis migratorius*. This salmonid fish, a member of the whitefish and lake herring family, represents the single most important species of modern commercial fishing on Baikal, accounting for more than two-thirds of the annual commercial catch. The omul is about twelve inches in length as an adult (between six and seven years) and has a delicate flavor, somewhere between that of lake trout and whitefish. It is said that no true Siberian dinner is complete without at least one dish of omul.

This fish is also known for giving a piercing cry when it is hauled from the icy waters. Thus, when residents of the area speak of someone who is given to extensive whining or complaining, they say, "He cries like an omul."

Lake Superior has the siscowet trout, or fat lake trout (known simply as "fats" to local commercial fishermen). This deep-water species is adapted for living in the intense cold and pressure of the depths of Lake Superior. As an adult, this fish weighs fifteen to twenty pounds; 30 to 50 percent of its body weight is natural oil. When hauled from 600 to 900 feet of water and laid on the deck of a ship, the fish succumbs to its own weight, and under the pressure of gravity its tissues compress, forcing out pools of oil.

Baikal has its own oily fish, the golomyanka. Two subgroups of this fish exist in Baikal and nowhere else. They differ primarily in length, one being approximately six inches long, the other slightly more than eight inches. The golomyanka bears live young. Each female produces about 2,000 progeny each autumn, and a large percentage of females do not survive the process. When they die, most sink to the bottom, but females of the larger golomyanka species frequently float to the surface and are washed ashore in great masses. Its large quantity of body oil, 35 percent or more by weight, makes the fish both transparent and buoyant. When cast ashore by wind and wave, these fragile creatures literally melt away in the heat of the sun, leaving only cartilaginous skeletal structures behind them. Like Superior's siscowet trout, Baikal's golomyanka are so adapted to cold water that temperatures above 45 degrees Farenheit are fatal to them. This fish remains in the dark, cold regions at depths of 700 to 1,600 feet during daylight hours, and migrates to the surface at night where it becomes the favorite food of another unique and endemic animal in the Baikal ecosystem, the nerpa, or freshwater Baikal seals, whose nearest relatives are to be found some 2,000 miles to the north in the Arctic Ocean. Known scientifically as *Phoca sibirica,* the nerpa has an estimated population in excess of 25,000 individuals. Some controlled hunting is still permitted, and the population continues to grow slowly. Because they are furtive creatures, the nerpas' exact population densities could not be determined until the advent of helicopter surveys. However, the lake's extreme transparency favors the census takers, since there is apparently no depth to which seals usually dive that cannot be observed from an aerial platform such as a helicopter.

The crustacean populations of Superior and Baikal may also be singular in the world. Superior supports a zooplankton community that is consistent with a deep, cold lake of high water

*Lake freighter on the southwest shore of Lake Baikal*

Paolo Koch, Photo Researchers

quality. Populations include such outstanding representatives as an opossum shrimp, *Mysis relicta.* Baikal, on the other hand, supports a unique, shrimplike amphipod found nowhere else in the world. Until recently, it was thought that Baikal also contained a singular multisegmented worm, a polychaete, that was unique. Not long ago, however, this creature, known as *Manayunkia baicalensis,* has been found to have a close relative, *M. eriensis*, in the Superior area and elsewhere in the Great Lakes.

Baikal is not only much older than Superior, but also has a greater number of species endemic to it alone. More than two-thirds of the plant species in the Baikal ecosystem fall into this category. One regrettable similarity between the lakes has more to do with human activity than with the lakes themselves. Since the late 1950s, industrial development has threatened to alter the ecology of both lakes. At about that time, a new technique for separating low-grade iron ore from its surrounding rock matrix was put into practice in a plant on the shores of Lake Superior. This plant released 69,000 tons per day of crushed rock flour into the Superior ecosystem. In addition to its effects on lake life, this material was later found to contain asbestos fibers, which had potentially serious health consequences for the region's human residents.

During the same time period, industrialization came to the Baikal basin. In 1957, an industrial division of the Soviet government suggested that the vast timber resources of the taiga and the pure water of the Baikal basin should be put to productive use. Planning announced the following year called for the development of two new major industrial developments—a cellulose factory on the Selenga River and construction of a facility to manufacture ultrapure cellulose cord for use in the production of airplane tires. This new plant was to be located at Baikalsk on Baikal's southern shore.

Meanwhile, on Lake Superior, the pulp and paper industries of both the United States and Canada were manufacturing large quantities of paper and pulpwood products from the vast stands of timber adjacent to the Lake Superior basin. Similarly, industrial development began along the Selenga River, some seventy-five miles upstream from the Baikal basin. A number of factories came into existence, contributing a substantial amount of waste material to Baikal. Baikal and Superior soon began to show the effects of this human activity.

On Baikal, as on Superior, commercial fishing began to be threatened by chemicals that were being liberated into the aquatic environment, particularly toxic phenols and their associated byproducts, which have major effects on taste and odors associated with the flesh of fish. On Superior, commercial fishermen began to cease taking whitefish from areas where exposure to phenolic wastes might taint their catches.

The phenolic residues from the Baikalsk cellulose plant on Baikal's southern shore also affected the catch of the omul. As soon as this was recognized, the Soviet government undertook a series of tough legislative measures that served to minimize the extent of the problem. Even this may not have been enough, however. The effluent from the Baikalsk plant consistently meets or exceeds the standards for water quality in the Soviet Union, but these standards are well below the ultrapure quality of the waters of Lake Baikal. Thus, it is currently reported that the cellulose plant will either have developed a closed-cycle system by 1985 or the plant will no longer be permitted to operate.

Legislative and judicial steps have also been undertaken to eliminate waste effluents entering Lake Superior from mining facilities. As a result of an extended contest in the courts, the mining company has now begun to dispose of its waste products at a land site. In addition, massive efforts through the International Joint Com-

*Cleaning up around Lake Superior*

Jim Brandenburg

*Fishing boats, Lake Superior*

Tom Stack; Tom Stack and Associates

mission, a treaty body established between the governments of the United States and Canada for the purpose of promoting water quality in the Great Lakes, have resulted in the identification of major problem areas related to water quality. Concerned scientists anticipate that as a result of the efforts of this body, effluent standards will be such that the problems of phenolic and other toxic discharges may soon be contained.

Regrettably, however, containment alone may not be sufficient. New and perhaps even more insidious threats, consisting of the introduction of man-made chemicals of recent origin, have been identified for both the Superior and Baikal ecosystems. First evidence of the potential impact of these compounds came from a study that was done on Lake Superior's Isle Royale. A rock-strewn conglomerate of island masses and associated irregular shore reefs, Isle Royale is seventeen miles from the nearest shoreward margin of Lake Superior at Thunder Cape, Ontario, and more than thirty-two miles from Thunder Bay, Ontario, the nearest major population center. The entire island structure, including its associated reefs and islets, was established as Isle Royale National Park in April 1940. Since then efforts have been made to retain the island's native wilderness character. Siskiwit Lake, a small, deep lake on Isle Royale, was selected for study of background levels of man-made toxic organic chemicals because it was remote from inhabited areas, and free from direct industrial and/or cultural influences attributable to humans. Furthermore, the areas surrounding Siskiwit Lake had never been logged nor had mining operations or the use of heavy equipment ever been permitted in the near vicinity. No internal combustion engines have ever been allowed, and even the air space above and adjacent to the park is restricted, thus avoiding localized contamination from aircraft. In short, a more isolated and remote spot is difficult to imagine.

*Picnickers, Lake Baikal*

Jerry Cooke

*Fishing boats, Lake Baikal*

Paolo Koch, Photo Researchers

Samples of fish from Siskiwit Lake were analyzed for man-made toxic contaminants. The results indicated a marked increase in toxic organic substances in Siskiwit Lake as compared with levels in fish taken from Lake Superior's surrounding water mass. This surprising evidence led to the conclusion that these substances had to have been airborne in order to reach this remote site. To test this hypothesis, samples of fresh snowfall from Siskiwit Lake were compared with similar fresh snowfalls in the metropolitan areas of Chicago, Illinois, and Duluth, Minnesota/Superior, Wisconsin. All samples were tested for polychlorinated biphenyl compounds (PCBs), ubiquitous, man-made toxic substances, and the mean value for PCBs in the snow from Siskiwit Lake turned out to be five times higher than similar values for the metropolitan areas sampled. This study suggested that long-range atmospheric transport of toxic organic substances was of major importance to the Lake Superior ecosystem.

With the knowledge that Lake Baikal is thousands of miles from any major source of toxic organic compounds of anthropogenic origin, researchers analyzed samples of deep sediments from the southern portion of the Lake Baikal basin and confirmed the presence of phthalic acid esters. Phthalate esters are used as plasticizing, or softening, compounds to make brittle plastics more pliable. The presence of such pollutants in such a remote ecosystem as Baikal again suggests the potential for long-range transport of products of our present technological age.

Because of the diffuse nature of these inputs, future control strategies and measures for the protection of both the Baikal and Superior ecosystems may be far more difficult than those required for previous actions. But, that it will be worth the effort to protect these two aquatic monarchs is without question. ☐

*What are the basic elements for successful open spaces in cities?*

**Text and photographs by William H. Whyte**

*With broad steps that provide good sitting space, sunshine, and an excellent view of the busy pedestrian traffic, the New York Public Library attracts a lively, social crowd.*

Ten years ago I formed a small group of observers and began looking at city streets and spaces in New York and how people used them. I did it because I thought it would be interesting, but as with all such enterprises, I had a proper research design and many fine hypotheses. Most were about overcrowding, which was then very much on peoples' minds. Experiments with mice were demonstrating that very high population densities induced neurotic behavior, and by inference, so did cities. What about people? How did they respond? How many were too many? In what circumstances? With the help of some foundation grants we set forth on our research—and a succession of broken hypotheses.

We started by looking at playgrounds and such informal recreation areas as city blocks. What soon struck us was the lack of crowding in many of these areas. A few were jammed, but more were nearer empty than full, often in neighborhoods that ranked very high in density of people. Sheer space, obviously, did not of itself attract children. But many streets did. One of the best play areas we came across was a block on 101st Street in East Harlem. It had its problems, but it worked. The street itself was the play area. Adjoining stoops and fire escapes provided prime viewing across the street and were highly functional for mothers and older people. There were other factors at work, too, and had we been more prescient, we could have saved ourselves a lot of time spent later looking at plazas. Although we did not know it then, this block had all the basic elements of a successful urban space.

As our studies took us nearer the center of the city, the imbalance in space use was even more apparent. Most of the crowding could be traced to a series of choke points—subway stations, in particular. Elsewhere, however, there was a surprising amount of underused space. Office building plazas were prime examples. Since 1961, New York City has been giving incentive bonuses to builders who provide public plazas; for each square foot of plaza, builders can add ten square feet of commercial floor space over and above the amount normally permitted by zoning. So they did—without exception.

We found that some plazas did attract people. The plaza of the Seagram Building was one. On a good day, there would be 150 people sitting, sunbathing, picnicking, and "shmoozing" —idly gossiping, talking "nothing talk." But on most plazas, there weren't many people. In the middle of the lunch hour on a beautiful, sunny day, the number of people sitting on plazas averaged four per 1,000 square feet of space, an extraordinarily low figure for so dense a center. was being had. For the millions of dollars of extra space it was handing out to builders, it had every right to demand much better plazas in return.

I put the matter to the people at the City Planning Commission. They agreed that tougher zoning was in order. If we could find out why the good plazas worked and the bad ones didn't and come up with hard guidelines, we would have the basis of a new code.

We set to work. We began studying a cross section of plazas, small parks, and street corners, and observing how people used such spaces. We mounted time-lapse cameras and recorded daily patterns. We talked to people too, but mostly, we watched them to see what they did. What attracts people, it became apparent, is other people. Many spaces are being designed as though the opposite were true, and that what people like best are the places other people stay away from. People often talk along such lines. They speak of getting away from it all, and use terms like "escape," "oasis," "retreat." What people do, however, reveals a different priority.

This was brought home to us in a study of street conversations. We wondered how far away people move from the main pedestrian flow when they stop to have a conversation. We were especially interested in finding out how much of the normally unused buffer space next to buildings was used. So we set up time-lapse cameras overlooking several key street corners and plotted the location of all conversations lasting a minute or longer. But the people didn't move out of the flow. They stayed in it or moved into it, and the great bulk of the conversations were held smack in the center of the flow—the "100 percent location," to use real-estate terminology. The same gravitation characterized "traveling conversations," those in which two men move about, alternating the roles of straight man and principal talker. There is a lot of apparent motion, but if you plot the orbits, you will find they usually revolve around the 100 percent spot. To a large degree, congestion is self-congestion. Just why, we have never been able to determine. That conversations should originate within the main flow is understandable. Where there are the most people, the likelihood of a meeting or a leave-taking is highest. What is less explainable is people's inclination to remain in the main flow, blocking traffic, being jostled by it. This does not seem to be a matter of inertia, but of choice—instinctive, perhaps, but by no means illogical. In the center of the crowd you have the maximum choice—to break off, to continue—much as you have in the center of a cocktail party, itself a moving conversation growing ever denser.

*Although quite loud, the sound of the waterfall in New York's Paley Park is a pleasant noise that masks conversation, thereby adding a feeling of privacy to a small, crowded area.*

People like to sit in the mainstream. At the Seagram plaza, the main pedestrian paths are on diagonals from the building entrance to the corners of the steps. These are natural junction and transfer points, and there is usually a lot of activity at them. They are also a favored place for sitting and picnicking. Sometimes there will be so many people that pedestrians have to step carefully to negotiate the steps. The pedestrians rarely complain. While some will detour around the blockage, most will thread their way through it.

Standing patterns are similar. When people stop to talk on a plaza, they usually do so in the middle of the traffic stream. They also show an inclination to station themselves near objects, such as a flagpole or a pillar. They like well-defined places such as steps or the border of a pool. What they rarely choose is the middle of a large space. The preference for pillars might be ascribed to some primeval instinct: you have a full view of all comers but your rear is covered. But this doesn't explain the inclination men have for lining up at the curb. Typically, they face inward, toward the sidewalk, with their backs exposed to the dangers of the street.

Foot movements are consistent, too. They seem to be a sort of silent language. Often, in a group no one will be saying anything. Men stand bound in amiable silence, surveying the passing scene, then, slowly, rhythmically, one of the men rocks up and down: first on the ball of the foot, then back on the heel. He stops. Another man then starts the same movement. Sometimes there are reciprocal gestures. One man makes a half-turn to the right; after a rhythmic interval, another responds with a half-turn to the left. Some kind of communication seems to be taking place here, but I have never broken the code.

Whatever they may mean, people's movements are one of the great spectacles of a plaza. You do not see this in architectural photographs, which typically are empty of life and taken from a perspective, often a misleading one, that few people share. At eye level you see movement and color—people walking quickly, walking slowly, skipping up steps, weaving in and out on crossing patterns, accelerating and retarding to match the moves of others. There is a beauty that is beguiling to watch, and the players themselves seem aware of it. With its brown-gray monochrome, the Seagram plaza is the best setting for them—especially in the rain, when an umbrella or two spots color in the right places, like Corot's red dots.

From city to city, behavior patterns are much the same. The strongest similarities are found among the world's largest cities. People in them tend to behave more like their counterparts in other world cities than their fellow countrymen in smaller cities. For one thing, big-city people walk faster and tend to self-congest more. In a brief comparison study we made in Tokyo, we found that the proclivity to talk in the middle of doorways and busy corners was just as strong as in New York. Similarly, in Milan's Galleria the conversational groupings were remarkably like the patterns on Seventh Avenue.

Next we turned to the physical characteristics of plazas and how they might explain why lots of people sat on some plazas, but only a few on others. I had hypothesized that sun patterns were the critical factor. For a while, our time-lapse studies bore this out: where the sun was, the people were; where it wasn't, they weren't. Then the correlation vanished. As June followed May and the weather got warmer, people sat almost anywhere, sun or shade. Sun was important to have, certainly; but it did not explain the differences in popularity of plazas.

Nor did the shape of plazas. Some urban designers were sure that the proportions of the spaces were critical, and they were especially interested in ruling out long, narrow spaces. But our findings afforded no documentation. Some long, narrow spaces looked

SUITS

Clarks

*"Undesirables" such as derelicts and winos tend to appear in empty areas that are unattractive to other people because of lack of sitting space or prohibitions against loitering or eating.*

terrible and were empty most of the time, but so were some square spaces. Two of the most successful places in the city were long, narrow spaces.

Could the *amount* of space be the key factor? A number of conservationists thought so; in their view, people seek open spaces as a relief from the overcrowding they normally experience. If we were to rank plazas by the amount of open space provided, there would likely be a rough correlation between the size of the plazas and the number of people using them. There was not; if anything, there was a reverse correlation.

We turned to the amount of sittable space. Here we got closer. We went on to check many other factors: enclosures, pedestrian flows, nearness to transit, and such. But as we piled up all the data, overlay by overlay, one major finding emerged: People tend to sit most where there are places to sit.

This may not be an intellectual bombshell, but at the time it was not at all obvious to a number of architects and planners. They believed aesthetics of design were what drew people to come and sit. Some still do.

The key variable, however, is sitting space, and the places that have it tend to be good in other respects as well. Sittable space means choice. It is all the better, of course, if the space is physically comfortable: benches with backrests, for example, or well-contoured chairs. But more important is that it be socially comfortable. That is why ledges are so functional. They give people lots of room to sort themselves out; all the more so if the ledges are two backsides deep.

Steps are also great for sitting. They give a fine view of the theater of the street and provide an almost infinite combination of groupings. Corners of steps are especially popular. The right angles are very good for groups and at lunchtime are quickly preempted for picnics. This should create conflict. Since people generally take the shortest cut, the corners of steps are also precisely where the pedestrian traffic is usually heaviest. Still it all seems to work out. For all the coming and going, the sitters seem quite comfortable. The walkers don't seem to mind either and will carefully negotiate their way through the sitters rather than detour to the open areas. Sometimes the whole length of the steps is blocked by sitters. This is a good sign, the hallmark of an unusually successful place.

Although benches can work well, too often they do not. They are usually too small; there are too few of them; and they are spotted in isolation, one from the other, like design objects. Benches should be generously proportioned and flexibly arranged. Fixed individual seats are not good. The trouble with them is that they are set pieces. Social distance is a subtle measure, ever changing, and since the distances of fixed seats do not change, they are rarely right for anybody.

Best of all is the movable chair. It is a splendid invention and for more reasons than comfort. Its movability is the secret. A chair provides the maximum amount of choice—in the sun, out of it, up front, to the back—and the possibility of choice is more important than the exercise of it. Watch people as they approach a chair. They will probably move it; there seems to be a deep impulse in us to do so. The move may be only a matter of a few inches and in many cases is followed by a series of countermoves, with the chair ending up where it was in the first place. But the moves have point; they are

an assertion of one's free will and satisfying to make.

Moves can also be a nice social ritual. When taking a chair next to some stranger, a person's moves say something to them. The message may be, Sorry about the closeness, but I'm going to respect your privacy as you will mine. A slight reciprocal move by one of the others may follow. Watching these exercises in civility is one of the pleasures of a good place.

Like a place to sit, the other major elements of a good urban space are basic, and while it might seem a contradiction in terms, they are *natural* elements. Sun, light, trees, water—nowhere is nature more important than in cities, where it is so marginal.

Sun is the prime example. True, a space can work without it. Paley Park in midtown Manhattan lost much of its sun to a building across the way; still it remains very popular. But something of great value has been lost. Watch how people make the most of what sun there is and you realize how primeval is our reaction to it.

We are losing sun to new construction at an alarming rate. The problem is not only the bulk of the buildings but also a design approach that virtually ignores the sun. Few buildings acknowledge their neighbors, nor are they required to. Incentive zoning has many bonuses for making buildings bigger, none for having them provide more sun. They could. The same buildings that block sun can also reflect it. On streets with buildings of limestone or other light-colored materials, the light bounced from them may make the shady side of the street measurably brighter. Such effects are inadvertent. Architects do sun studies for new buildings, more for defensive than other reasons, and tend not to fret over the consequences of shadows on other buildings. Neither do they consider the sun's positive benefits. With certain small changes, such as canting reflective panels on part of

*A band of street musicians attracts a crowd and provides a linkage between people, encouraging strangers to talk to each other when under ordinary circumstances they would not.*

*A movable chair provides the most choice in establishing social distance. The impulse to move the chair—even if only a few inches and with the chair ending up in its original position—is irresistible.*

a tower, the architect could bounce some much needed light into dark places—Paley Park, for example.

Water is an element that designers are using rather well. Some plazas and parks now provide waterfalls, waterwalls, sluiceways, water tunnels, meandering brooks, tranquil pools, or fountains. The sound of water may be its best feature; a waterwall is loud—about 75 decibels—but it is a "white" sound that masks street noises and other people's conversations.

Another good thing about water is the look and feel of it. I have always thought the water at the Seagram plaza is unusually liquid, and I think it's because you know you can splash your hands or stick your toes in it if you are of a mind to. Not so in some places. A guard will come up. Forbidden. Pools of water are set before people and then posted with signs telling them not to touch the water. In Chicago's Grant Park, the grand old Buckingham Fountain has been put off limits with an electrified fence around it.

Safety is the reason usually given for such measures, but there are better ways than electrocution to handle this problem. At the Auditorium Forecourt Fountain in Portland, Oregon, people have been clambering up and down its sluiceways and falls for some seven years. While it looks dangerous—designer Lawrence Halprin designed it to look that way—there have been no serious mishaps since the day it opened. This splendid fountain is an affirmation of trust in people and it says much about the good city of Portland.

Trees are so obvious an amenity, the wonder is we haven't planted far more of them. In addition to their many other virtues, trees make the best of a sitting space. They provide a satisfying enclosure: sitting under one you can see all of the passing scene, while feeling somewhat protected, cuddled—much as you do under the awning of a sidewalk cafe. Builders should be required to plant many more trees and, where possible, to plant them in groves. The overlapping foliage makes a fine canopy. Arbors can do the same.

Another basic is food. People will eat an astonishing amount of it outdoors, and if you want to seed a place with activity, food facilities will do it. Even a pushcart can be a strong draw. In New York you will see a pushcart vendor and a knot of people around him at almost every plaza or set of steps with a lively social life. Sometimes the police arrive with trucks and haul the carts away, a piece of street theater invariably greeted with boos from the bystanders. Some cities are much more puritanical; they forbid not only the purveying but also the eating of food outdoors.

They are robbing themselves of a dynamic. Food has a strong shill effect. Out of proportion to their numbers, people who eat ice cream cones, hot dogs, and lunch out of brown bags attract other people. There has been a notable increase in the use of plazas where tables, chairs, and snack bars have been set up. From the street it sometimes looks as if a big party is going on and the sight induces passersby to venture in.

Now we come to the key space for a plaza. It is not the plaza; it is the street. A good plaza starts at the street corner. A busy corner has a brisk social life of its own, and there will be considerable two-way traffic between plaza and corner. Another key feature of a street is retailing—stores, windows with displays and signs to attract your attention, doorways and people going in and out of them. Big new office buildings have been eliminating stores, replacing them with a frontage of plate glass through which you can behold bank officers sitting at desks. One such stretch is dull enough; block after block of them creates overpowering tedium.

The area where the street and the plaza, or open space, meet is a key to success or failure. Ideally, the transition should be such that it is hard to tell where one ends and the other begins. New York's Paley Park is the best of examples. The sidewalk in front is an integral part of the park. Arborlike foliage extends over the sidewalk. There are urns of flowers at the curb and curved sitting ledges on either side of the steps. In this foyer you can usually find somebody waiting for someone else—it is a convenient rendezvous point—people sitting on the ledges, and in the middle of the entrance, several people in conversation. Even passers-by who don't go into Paley benefit. About half will turn and look in. Of these, about half will smile. I haven't calculated a smile index, but this vicarious enjoyment is extremely important—the sight of the park, the knowledge that it is there, becomes part of the image we have of a much wider area. If one had to make a cost-benefit study, I think it would show that secondary use provides as much, if not more, benefit than the primary use.

If such places are so felicitous, why are there not more of them? The reason is the "undesirables." They are not, themselves, much of a problem. The problem is the measures taken to combat them. Many businessmen have an almost obsessive fear that if a place is attractive, it might attract undesirable people. So the area is made unattractive. There is to be no loitering, no eating, no sitting. Benches are made too short to sleep on, and spikes are put in ledges; most important, many needed spaces are not provided at all, or the plans for them scuttled.

Ironically, places designed with distrust get what they were ostensibly avoiding and it is in such places that you will most likely find a wino. You will find winos elsewhere, as well, but they prefer the empty places. The best way to handle the problem of undesirables is to create an area attractive to everyone else. The record is overwhelmingly positive on this score. With few exceptions, plazas and small parks in most central business districts are probably as safe a place as you can find during the times that people use them.

There is one more factor to consider. I call it triangulation. By this I mean that process by which some external stimulus provides a linkage between people and prompts strangers to talk to each other. There are, say, two men standing at a street corner. A third man appears, hoists a sign, and begins a loud harangue on the single tax. This links the first two men. Casually, they exchange comments on the scene before them, in a tone of voice usually reserved for close friends.

Musicians and entertainers also draw people together. Rockefeller Plaza and the First National Bank of Chicago regularly schedule touring school bands, rock groups, and the like. The real show, however, is usually the audience. Many people will be looking as much at each other as at what is on the stage.

Street performances are great crowd gatherers, and they have the virtue of unexpectedness. When people form a crowd around an entertainer—it happens very quickly, in 40 or 50 seconds–they look much like children who have come upon a treat; some will be smiling in simple delight. These moments are true recreation although rarely thought of as such, certainly not by the shopkeepers who try so hard to outlaw them. But people like them, and they are right.

I am not, heaven forfend, arguing for places of maximum gregariousness or social directors for plazas. Anomie would be preferable. What I'm suggesting, simply, is that we make places friendlier.

I am, in sum, advocating busy places. Too busy? Too crowded? I think not. People have a nice sense of the number that is right for a place, and it is they who determine how many is too many. Furthermore, they do not seek to get away from it all. They go to the lively places where there are many people. And they go there by choice, not to escape the city, but to partake of it. ☐

*Food facilities act as magnets to draw crowds. The sight of other people eating ice cream, hot dogs, or ethnic foods gives the street a party atmosphere that induces passers-by to join in.*

# Quakes along the Mississippi

*In the central part of this river valley, an ancient split in the earth's crust is the site of continuing seismic activity*

**by Robert M. Hamilton**

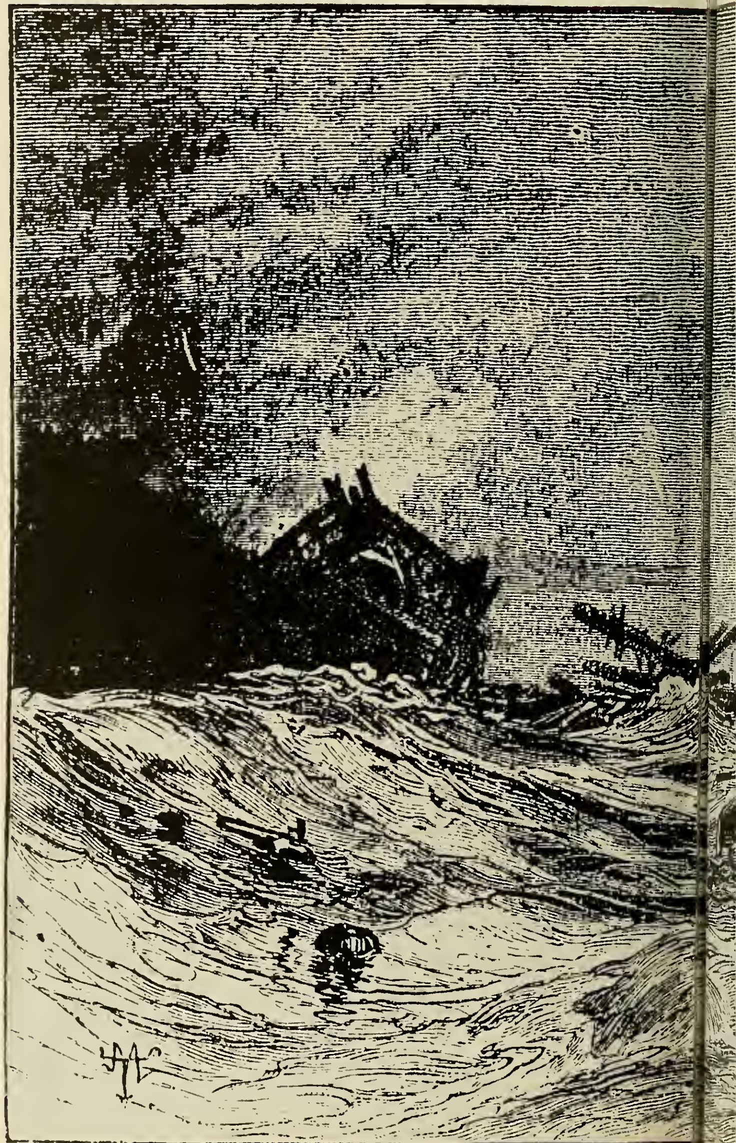
In the winter of 1811–12, the central Mississippi River valley was ravaged by a series of strong earthquakes. Spectacular disruption of the land took place over a vast area between the confluence of the Ohio and Mississippi rivers on the north and Memphis, Tennessee, on the south. Forests were flattened, chasms opened so wide that people felled trees to get across them, and land sank and was flooded to depths of several feet. Steep banks collapsed along the Mississippi and rapids formed in the river, which was even seen to reverse its direction of flow for awhile.

The first shock struck without warning at 2:00 A.M. on December 16, 1811, and was followed by hundreds of strong tremors. Similar strong quakes on January 23 and February 7 in 1812 were also followed by many aftershocks.

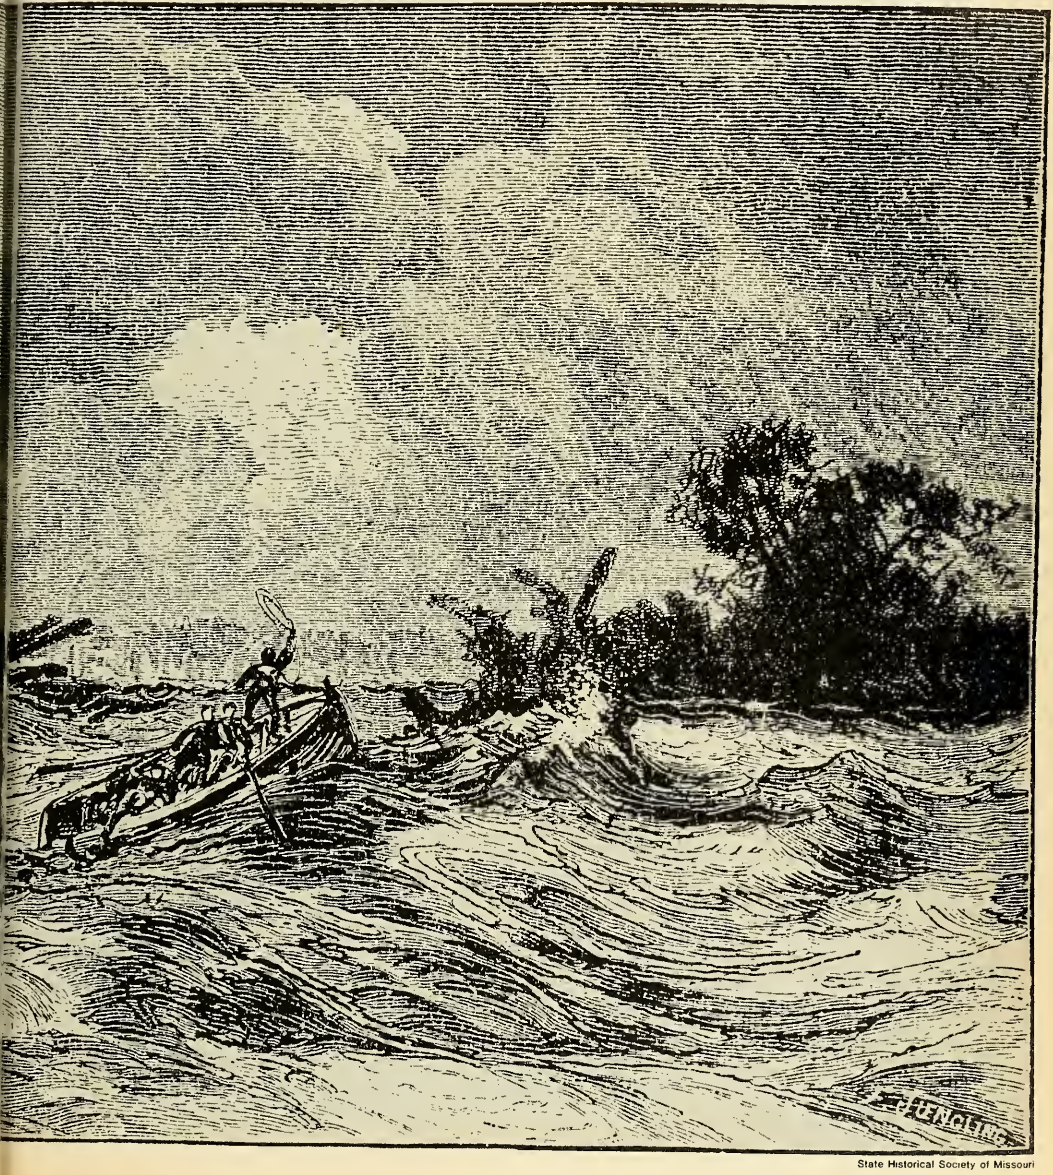
The most severely affected stretch of the Mississippi River was thinly populated at the time of the earthquakes. New Madrid, Missouri, perched above a sweeping bend in the river, was the main settlement in the region. In 1810, about 3,165 people lived in the area, which later became New Madrid County. Only a few of the settlers died, but hundreds of people were traveling or transporting goods on the river when the shocks struck, and casualties on the water may have been more numerous than on the land, although no reliable estimates are known.

The earthquakes virtually destroyed New Madrid. Most of the structures were tumbled by the first tremors, and the site of the town sank fifteen feet. The awesome effects on the land and the aftershocks, which continued intermittently for more than a year, so demoralized the inhabitants that many abandoned the area.

We have scant reliable information about the New Madrid earthquakes. The shocks predate the late-nineteenth-century development of the

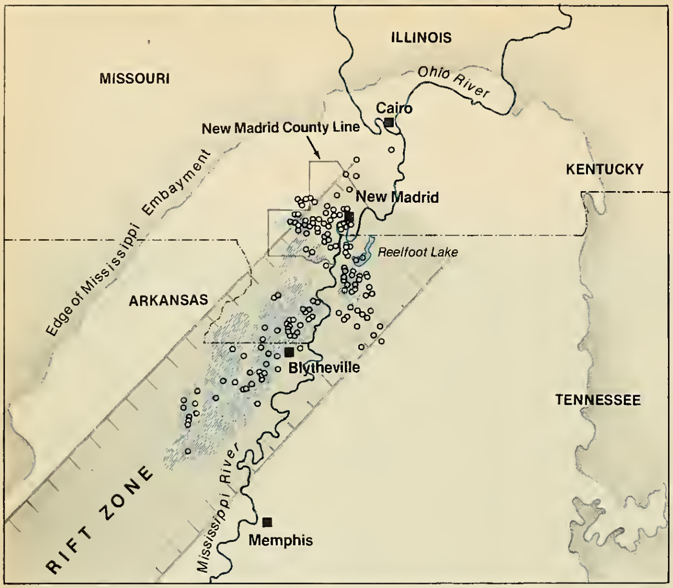


*The Mississippi River during the 1811–1812 earthquakes as depicted in a nineteenth-century book.*



State Historical Society of Missouri

**Rift Structure in the New Madrid Area**



Joe LeMonnier

*Light blue areas indicate regions where sand was ejected onto the land surface during the 1811–12 earthquakes. Sand distribution is part of the data showing the location of those shocks. No primary surface faulting was associated with them. Circles show epicenters of earthquakes in the last few years. The exact boundaries of the Rift Zone are not known.*

seismograph, the instrument for recording earthquakes. Even without instrumental data, however, we can estimate the magnitude of the earthquakes on the Richter scale by comparing the size of the areas affected with those of modern earthquakes. Such a comparison indicates that the three strongest quakes were between 7 and 7.5 in magnitude. Earthquakes of magnitude 6 or greater in populated areas are usually destructive. For example, the earthquake that caused severe damage at San Fernando, California, in 1971 was of magnitude 6.4.

Much of what we know about the effects of the New Madrid earthquakes comes from fragmentary accounts of inhabitants and travelers in the area when the quakes struck and of scientists and naturalists traveling through the area before the effects eroded away or were otherwise obscured. Among the distinguished observers who visited the region were John James Audubon, the famous ornithologist-naturalist, and Sir Charles Lyell, the English geologist whose work on the association of geologic formations with fossils helped pave the way for Darwin's theory of evolution.

The most lasting effects of the earthquakes are the extensive lowlands, or "sunken lands," of northeastern Arkansas, southeastern Missouri, and northwestern Tennessee. Reelfoot Lake, in Tennessee, was enlarged and deepened by the quakes. Consequently, many hardwood and cypress trees died and their stumps can be seen in the lake today. Near Blytheville, Arkansas, an area of more than twenty-five square miles was covered by about three feet of extruded sand that came from deposits less than fifty feet deep. Liquefied by shaking from the earthquakes, the deposits were then ejected through cracks in the clay and silt of the river valley. The ground tremors from the earthquakes were described in vivid terms by those who experienced them, with the sensations being likened to the final cataclysm as the ground heaved and ruptured.

The cause of the New Madrid earthquakes has been a major seismological mystery. Most of the world's earthquakes take place where the large plates of rock that constitute the earth's outer shell separate, scrape past each other, or collide. These plates, which are a maximum of about fifty miles thick, float on the hot, partially molten interior of the earth in much the same way that solidified rock floats in a lava lake in the crater of a volcano or that ice sheets float on water. But the plates are vastly greater in size and their rate of movement is very slow (on the order of a few inches a year). In contrast to earthquakes in California and Alaska, which are known to result from the scraping and colliding of the Pacific and the North American plates, the New Madrid earthquakes took place well within the North American plate, where relatively little splitting of the continent has taken place in geologically recent time.

Important clues have recently been uncovered that suggest a solution to the mystery of the New Madrid earthquakes. Teams of government and university scientists have used new techniques, as well as some that have been employed in oil prospecting for more than a decade, to compile a convincing array of revealing data. The source of the New Madrid earthquakes now appears to be a deep break in the North American plate, referred to as a rift, that formed at least 500 million years ago. This rift extends all the way through the crust, to depths of more than twenty-five miles. Occasionally, the highly stressed continental rocks slip suddenly along this weak zone, shaking the ground intensely in an earthquake.

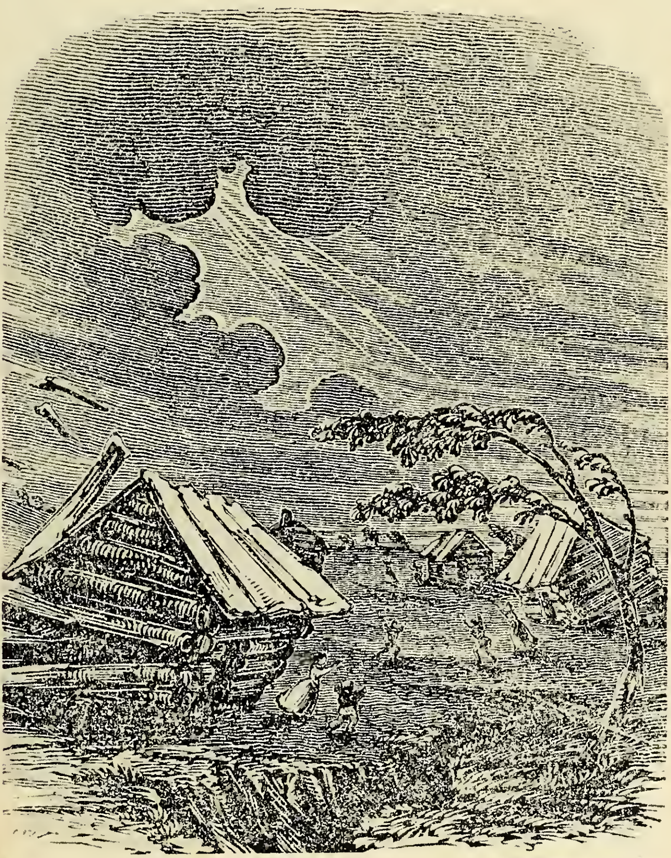
The importance of understanding the cause of the New Madrid earthquakes lies in the realization that sooner or later similarly strong earthquakes will strike again in the same region. The geologic forces causing earthquakes in the New Madrid area, or anywhere for that matter, are associated with the forces that build mountains and drive the plates. They are consequently of a long-term nature. The general characteristics of seismicity persist for time intervals measured in millions of years.

An appreciation of the potential damage of earthquakes in the New Madrid region can be gained by considering the area affected by the

11–12 tremors, particularly in comparison with other great United States earthquakes. Residents of Washington, D.C., at a distance of 750 miles, clearly felt the New Madrid earthquakes—doors and windows rattled, chandeliers swung. In Boston, about 1,000 miles away, church bells rang from the shocks. The earthquakes were also distinctly experienced in Charleston, South Carolina, where a somewhat smaller but similarly widely felt earthquake occurred in 1886.

The vast areas affected by these eastern earthquakes contrast sharply with the much smaller areas affected by large western earthquakes. For example, the 1906 San Francisco and 1964 Alaskan earthquakes, both greater than magnitude 8 on the Richter scale, were felt no more than a few hundred miles away. This difference in area affected is caused by the more rapid dying out of seismic waves in the West compared with the East, presumably owing to differences in crustal structure and the presence of hotter rock at depth in the West.

The new information about the cause of the New Madrid earthquakes has been derived in the last five years, largely as a result of intensified studies aimed at evaluating the earthquake threat in quake-prone areas of the United States. Earthquake studies in the New Madrid seismic region are hampered by the nature of the geologic setting. The area lies at the northern end of a major geologic structure known as the Mississippi Embayment. The embayment is a downwarped trough of hard Paleozoic rocks filled with relatively soft rocks ranging in age from about 100 million years to recent times. These soft rocks, mostly sandstone and clay, were deposited while the embayment was sinking. Because the rocks are soft, the geologic record of long-term fault movement is not well preserved; therefore the nature of faulting in the embayment in relation to that in the surrounding region is difficult to determine. The soft sediments of the embayment effectively veil the deep earthquake-related geologic features and necessitate the use of expensive, sophisticated geophysical methods that can "see" through the sediments to basement rock.



*Period woodcut of New Madrid quakes.*

State Historical Society of Missouri

A moderately dense network of sixteen seismograph stations, operated in the New Madrid region by Saint Louis University, provided important new information. Seismograph stations are used for determining the source location, or focus, of earthquakes. The point on the earth's surface above the focus is called the epicenter. The more stations there are in a seismic area, the more accurately the epicenters can be determined.

Before installation of the dense seismograph network, the seismicity pattern appeared diffuse, like the scatter of holes from a shotgun blast. The improved location accuracy of the dense network brought a welcome surprise: the diffuse pattern of epicenters was resolved into a few linear zones of seismicity. The linear nature of the zones revealed the approximate location of the earthquake-causing faults. Other data gleaned from the seismograph stations showed the direction of slip on these faults.

Surveys of the magnetic and gravitational fields in the New Madrid region by scientists of the U.S. Geological Survey and Purdue University provided additional clues. The hard Paleozoic sedimentary rocks of the Mississippi Embayment have had many igneous rocks intruded into them. The igneous rocks came from great depths, were injected into the sedimentary rocks as molten masses of various shapes, and then cooled. These intrusive masses, called plutons, are denser and more magnetic than the surrounding rock, which is mostly limestone and dolomite, so they cause strong anomalies in the gravity and magnetic field. Where the plutons are more deeply buried, the anomalies are less sharply defined than anomalies caused by plutons close to the surface.

The surveys revealed a band of relatively weak anomalies cutting north-

eastward across the seismic zone. It is inferred that this band corresponds to a downdropped block of the shallow crust that slipped to a position about a mile lower than its original position, analogous to the way the keystone in an arch would drop if the supporting columns were moved apart.

The downdropped block delineated by the magnetic and gravity data is known in geologic terms as a rift. Such a feature can form where molten rock penetrates the lower crust, causing uplift and stretching of the upper crust. Numerous faults are formed as a result, and blocks of the extended crust collapse to form the rift. The main zone of seismicity in the New Madrid region is coincident with the middle of the rift, indicating that the weakest part of the rift is along its axis.

The first information on the detailed structure of the rocks in the seismic region was provided by a technique much used in the search for petroleum, but little used in earthquake studies because of its cost. Known as seismic-reflection profiling, the technique is basically very simple.

Seismic waves are generated at the land surface either by explosions or, more commonly these days, by vibrating pads mounted on trucks. The waves propagate downward into the crust, and as each layer of rock is encountered, part of the wave energy bounces back. Along the ground, a line of instruments called geophones, which sense ground vibrations, is deployed from the trucks to a distance of about a mile to detect the returning energy and to record the precise time of its arrival. The elapsed time between sending and receiving the wave energy, together with information about wave velocity through the rocks, yields an estimate of the depth of each reflecting layer. By combining data from many vibration points, we can construct a picture that shows the approximate configuration of rock strata beneath the survey line. In effect, what we have is a cross section of the earth's crust that resembles a slice of layer cake.

Thus, seismic-reflection profiling makes it possible to map the configuration of rock strata deep in the crust and to delineate faults and folded strata that may be associated with earthquakes. In 1978 and 1979, extensive profiling, along about 170 miles of lines, was done in the New Madrid region with impressive results.

A major fault zone, coincident with the main zone of seismicity, was found below the soft sediments. This fault zone is probably the source of at least two of the three largest shocks that took place in 1811–12. Strata across the fault zone are arched and faulted, much as would be expected from continental rifting. Most of this deformation occurred about 300 million years ago, but there is clear evidence of more recent faulting in the rift structure.

In addition, a northeast-trending set of faults was found that appears to have moved substantially in geologically recent time. The youngest strata seen are vertically offset by about 250 feet. This fault movement, which certainly took place during the last 50 million years, the age of the youngest beds seen to be disrupted, could have occurred entirely within the last few thousand years.

The zones of faulting found by seismic-reflection profiling lie along the rift axis, where the main seismic zone also falls. Plutons, the intrusive masses of molten rock, likewise are present along the rift axis. Their presence indicates that the faulting extends through the crust and serves as a conduit for the molten rock.

Piecing these fragments of information together, we can reconstruct a skeletal geologic history of the northern Mississippi Embayment. Before about 500 million years ago, geologic forces caused uplift of a large area of the Central Mississippi Valley. The uplift probably resulted from upwelling of magma from deep in the earth's hot interior. It caused the crust of the earth to stretch and break, and large blocks of rock were dropped down in a long zone to form a rift.

From 500 to about 300 million years ago, the rift area was sinking, the sea was encroaching, and thick sediments, first of sand and clay and later of limestone and dolomite, were deposited. Sometime between 300 million and 200 million years ago, the land rose again, the sea withdrew, and much of the accumulated sediment eroded away. While the land was rising, igneous intrusive activity occurred and plutons were emplaced in another stage of rift activity.

As the episode of rifting subsided, the land gradually sank, and by 100 million years ago the sea had once again covered the region. Additional episodes of igneous intrusive activity took place in the embayment about 100 million years ago and possibly again less than 50 million years ago. After this last episode, substantial fault movement occurred, probably associated with minor rifting.

The net result of all this geologic activity is that the earth's crust in the embayment is badly weakened. The embayment is, therefore, a place where the crust breaks repeatedly as the stresses associated with movement of the plates bring pressure to bear.

A natural question to ask is, When will a strong earthquake again strike the New Madrid region? The answer is we don't know because earthquake prediction is not yet reliable even in the best-studied areas, such as California, and relatively little work has been undertaken toward prediction in the New Madrid region. Nevertheless, evidence indicates that, on the average, strong earthquakes strike the region about every 600 years. Of course, several such shocks could strike in a short time span, followed by a long period of inactivity. In terms of planning, the best policy is to recognize the inevitability of future, damaging earthquakes in the New Madrid region and to incorporate earthquake resistance in the design and construction of important structures. ☐

Stop the Great Heat Escape!

**Window Quilt™** cuts window heat loss up to 79%

**If you're serious about home heating efficiency**, you already know that far more heat escapes through windows than walls, roof or doors. You can pack your walls with thick insulation, install tight-fitting storms or double glazing. Even so, you'll most likely loose *more than half* your precious winter heat through your windows.

**Window Quilt™** multi-layered thermal shades can eliminate up to 79% of winter heat-loss through single-glazed windows, as much as 66% through double-paned glass.

Window Quilts fit tightly on all four sides, sealing warm air in and cold air out. They're easy to install and operate, easy to live with, far more efficient than ordinary shades or insulated drapes.

The secret of Window Quilt's amazing efficiency: A thin foil layer is surrounded by layers of insulating fiberfill with polyester covers, all quilted by ultra-sonic stitching.

• Fit almost any size window, even 8' wide sliding glass doors. • More than twice as effective as storm windows, better than 4 glazings (R value: 4.25) • In snow country, with double glazing one sq. ft. saves 1 gal. oil per year. Payback is 2-5 years • Helps keep summer heat out — saves on air conditioning. • Attractive quilted design and neutral bone-white color enhance any decor.

**Window Quilt™**

☐ Here's $2. Rush me your literature portfolio, a worksheet to figure my energy savings, measuring guide, dealer listing, and actual Window Quilt sample.

☐ Here's 25¢, send brochure and names of dealers near me.

REAL TEXAS CHILI! Recipe plus seasoning, serving hints. $2.00 postpaid. Bright Enterprises, Box 4759-NH, Austin, TX 78765

SHAKER BAKERY. 6 authentic, naturally delicious, ingeniously simple recipes of historic sect. $3.00 SASE. Box 300, Germantown, MD 20767

### Government Surplus

"GOVERNMENT SURPLUS DIRECTORY." Buy 500,000 items (including Jeeps) . . . low as 2¢ on dollar! Most complete information available—$2.00. Surplus Disposal, Box 19107-RV, Washington, DC 20036

JEEPS—$19.30!—CARS—$13.50!—650,000 Items! —Government Surplus—Most Comprehensive Directory Available Tells How, Where To Buy—Your Area—$2—Moneyback Guarantee—"Government Information Services," Dept. DC-8, Box 99249, San Francisco, CA 94109

### Merchandise

HAVE DRUGLESS SINUS RELIEF!! Sinus sufferers. Find natural relief. This drugless method is inexpensive and used by doctors worldwide. Informative booklet explains all and is available by sending $1.00 to Hydro Med (NH), P.O. Box 91273, Los Angeles, 90009

IMPROVED WATERPROOF FIELD PAPER. Write or draw outdoors in any weather. Unlined 8½ × 11 samples $3 (guaranteed!). Waterlog, Box 489F, Toledo, OR 97391

WALKING STICKS, CANES, Free color brochure, Marchele Co., Dept. NHH, 1123 Broadway, New York, NY 10010

### Music

FREE CATALOGUE. Musical instruments and kits—Harpsichords, Hammered and Appalachian dulcimers, lutes, guitars, etc. HDC, 4419 West Colfax, NH, Denver, CO 80204

### Old Time Radio

OLD TIME RADIO PROGRAMS on cassette tapes. Free catalogue. Cassette Library Center, P.O. Box 5331H, Baltimore, MD 21209

### Photo/Optical

BINOCULAR SALES AND SERVICE. Repairing binoculars since 1923. Alignment performed on our U.S. Navy collimator. Free catalogue and our article "Know Your Binoculars," published in Audubon Magazine. Mirakel Optical Co., Inc., 331 Mansion St., West Coxsackie, NY 12192 (518) 731-2610

BIRDERS, NATURALISTS, PHOTOGRAPHERS. Highest quality 35mm slides from the collection of the Cornell University Laboratory of Ornithology. Birds, wildflowers, reptiles, amphibians. Free catalogue. Dept. 44, 159 Sapsucker Woods Road, Ithaca, NY 14850

LEITZ, ZEISS, B&L, SWIFT, BUSHNELL, NIKON, Optolyth binoculars, telescopes and accessories. Send stamp for discount list. Specify literature desired. Large stock. Orders filled postpaid day received. Birding, Box 5N, Amsterdam, NY 12010

OPTIC DISCOUNTS: Binoculars—Telescopes—Brand Names—Free Catalogue. Thos. Manetta, 61 Hoffman Ave., Elmont, NY 11003

PHOTOGRAPHY POSTERS: Brassai's portrait of Picasso, Caponigro's "Stonehenge" . . . Catalog. $1 (refundable). Positive Images, Box 1939NH2, Kingston, NY 12401

### Plants

BROMELIADS! IDEAL HOUSE PLANTS, from Private Collections! Send $1, plus SASE; Pat's Plants, 140 Calais Court, Roswell, GA 30075

### Real Estate

"EXCLUSIVE" QUEBEC LAND for your Off-Season Home. Choice lot only 40 miles north of Montreal for either year-round living or as a recreational summer and winter retreat. Excellent investment opportunity. Some lots with river frontage. For as low as $1,995.00 —money back guarantee. This offer won't last. Write Laurentian Estates, Dept. 106C, 286 Lawrence Avenue West, Toronto, Ontario M5M 3A8 or call (416) 789-4536

FIVE ACRES—Thirty miles south of the Grand Canyon—Arizona. Elevation 6,000 ft. $22,500 By owners. Box 1133, Phoenix, AZ 85001 (602) 279-0232

FREE . . . 296-PAGE CATALOGUE. Describes and pictures over 2,700 farms, ranches, acreages, businesses and town and country homes from coast to coast. United Farm Agency, Inc., 612-U W. 47th St., Kansas City, MO 64112. Ph. Toll-Free: 1-800-821-2599; MO. Res. Ph. Toll-Free: 1-800-892-5785

GOVERNMENT LANDS . . . FROM $7.50/ACRE! Homesites, farming, vacationing, investment opportunities! "Government Land Buyer's Guide" plus nationwide listings—$2.00. Surplus Lands, Box 19107-RV, Washington, DC 20036

NEW! FREE! Big Fall-Holiday Catalogue! Over 5,400 country properties described, pictured! Land, Farms, Homes, Businesses, Recreation, Retirement buys! Selected best thruout the U.S. Over 700 offices, 43 states All Across America! Yours Free from the World's Largest! Strout Realty, Inc., 60 E. 42nd St., Dept. 5390, New York, NY 10017

### Resorts

FREE! Map/Birdlist—Chiricahua Mountains Area—plus illustrated brochure of our nature lovers' retreat—Cave Creek Ranch, Box F-1, Portal, AZ 85632

LITTLE ST. SIMONS ISLAND, Georgia. Enjoy birding, hiking, photography, beachcombing or just relaxing on this beautiful, secluded, 12,000-acre island with miles of unspoiled ocean beaches. Maximum of 10-15 guests. Excellent food. Professional naturalists on staff. Little St. Simons Island, Box 1096-N, St. Simons Island, GA 31522

MAINE: remote lodge, great walking, foliage, moose watching. Excellent food, maximum 10 guests. Little Lyford, Brownville, ME 04414

### Tours/Trips

ADVENTURES WITH WILDLIFE—Observe whales in breeding lagoons at San Ignacio and Magdalena Bay. Hawaiian Humpback Whale expedition; photograph polar bears in Canadian arctic; Andes, Amazon and Galapagos wildlife adventure in South America. Kenya, Zambia and Zaire safaris. Small groups conducted by expert naturalists. Adventures International, 4421-N Albert, Oakland, CA 94619

ADVENTUROUS NEPAL-INDIA-CEYLON-Pakistan by Geeta Tours & Travels. 1245 Jarvis, Chicago, IL 60626 (312) 262-4959

DAYTRIPS IN EUROPE for do-it-yourself travelers! Let our unique publications guide you through unusually fascinating places. Ideal for railpass users. Free catalogue. Great Trips, Box 5199-N, New York, NY 10163

DISCOVER THE YUKON: "Gentle Adventure"! Drift with us on a 10 day raft or boat trip along 220 miles of untouched river wilderness. Contemplate the unforgettable beauty of the Canadian North with a seasoned naturalist. Personally guided by John Lammers, President, Yukon Conservation Society. Maximum 6-8 persons. Call for brochure: (212) 682-0480 (NYC) or write: Yukon Wilderness Unlimited, Box 4126, Whitehorse, Yukon, Canada (403) 633-5250

HIMALAYAN TRAVEL, INC. Trekking expeditions in the Everest and Annapurna areas of Nepal. Free brochure. Box 481-NH, Greenwich, CT 06830. Toll free (800) 243-5330

NATURALIST GUIDED FIELD SEMINARS and tours, West Texas and Mexico. Rafting, hiking, backpacking, bus. University or Continuing Education credit as appropriate. Write Education Department, Chihuahuan Desert Research Institute, Box 1334, Alpine, TX 79830

NATURE PHOTOGRAPHY field work and instruction in the spectacular North Cascades. Backpack, walking pack trips and workshops with professional guide/photographers. The Natural Image, P.O. Box 45, Winthrop, WA 98862

NATURE TOURS emphasizing birds, mammals, wildflowers. Small groups to Himalayas, Bhutan, Colombia, Sierre Leone. World Nature Tours, Box 693a, Silver Spring, MD 20901

NEW ZEALAND WALKABOUT: Escorted nature tours featuring excursions in New Zealand's scenic National Parks, plus the Milford Track. Pacific Exploration Company, Box 3042-N, Santa Barbara, CA 93105

ROAM THE WORLD BY FREIGHTER! Deluxe accommodations. Cheaper than staying home! TravLtips, 163-09B508 Depot, Flushing, NY 11358

SUDAN, EGYPT, TANZANIA. Tribes/Wildlife. Departs December 13—$5,500. Capers, Box 5489, Beverly Hills, 90210

WILDERNESS ALASKA. Cruise among eagles, whales, glaciers and fiords. Arctic Tramp, Box 827, Valdez, AK 99686

### RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# Celestial Events

by Thomas D. Nicholson

**The Moon** The moon is a morning object in early August and September, rising after dark and setting in daylight. The evening crescent appears just before the middle of each month, and from then until the last week the moon is up at sundown, brightening the early night. August phases are: last-quarter on the 3rd, new on the 10th, first-quarter on the 18th, and full on the 25th. Last-quarter appears again on the 1st of September, new moon on the 9th, first-quarter on the 17th, and full (the harvest moon) on the 24th.

**Stars and Planets** Venus is a spectacular morning star in August and September, rising about 3½ hours before the sun and visible in the east until daylight. It is the only planet well placed for viewing in these months. Mercury moves from Gemini through Cancer into Leo in August and into Virgo in early September. Venus spends time in five constellations. Starting from Taurus and with a brief stay in Orion, Venus is in Gemini most of August and in Cancer most of September but moves into Leo late in that month. Mars is in Virgo; Jupiter and Saturn are in Leo in August but move into Virgo in September; Uranus is in Libra; Neptune is in Ophiuchus; and Pluto is in Bootes.

August 5: The star near the crescent moon at dawn this morning is Aldebaran, in Taurus.

August 6–7: The moon will be close to Venus at dawn on these days.

August 10: Today there is a partial solar eclipse in the southwestern and southern United States, and in Central and South America. It is an annular eclipse along the central line in central South America.

August 10–14: These are the mornings (from 1:00 A.M. on) to look for the Perseid meteor shower, the most reliable and productive (50 meteors per hour at maximum) of the year. The shower will be best on the 12th, but a good shower (25 or more per hour) should be visible on other mornings.

August 12–13: You may just be able to see Jupiter and Saturn on these evenings if you can see the crescent moon in the west after sundown.

August 15: Look for Mars, not very bright, near the moon tonight. The planet is just north of Spica, the bright star of Virgo, passing the star on the 17th.

August 24: Venus is at its maximum distance to the sun's right (greatest westerly elongation), placing it in a most favorable position as a morning star.

August 25: A penumbral lunar eclipse will produce a barely perceptible dimming of the full moon early tonight.

August 26: Mercury, in superior conjunction, becomes an evening star.

September 5: Be sure to see the very close conjunction of the moon and Venus this morning (an occultation elsewhere).

September 13: Jupiter, in conjunction with the sun, becomes a morning star. The moon is near Mars this evening.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you face the other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the sky at about 11–12 P.M. on August 1; 10–11 P.M. on August 15; 9–10 P.M. on August 31; and 8–9 P.M. on September 15. It shows only planets and moon phases above the horizon at those times, and all times are EST.

# Galactic Go-around

*The material in spiral galaxies does not move in the manner astronomers expected*

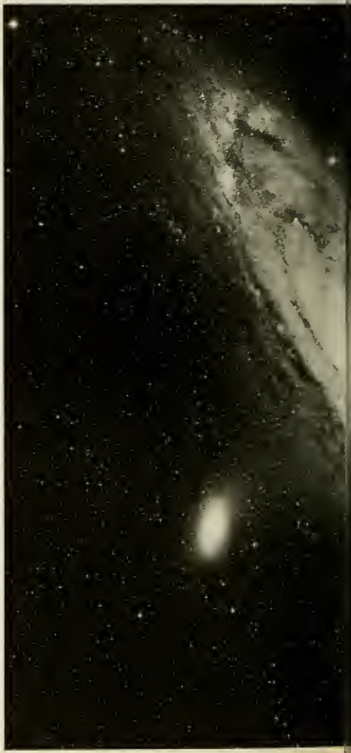
**by Vera C. Rubin**

When you look up at the sky on a dark night in the Northern Hemisphere, all of the stars you see with the naked eye are members of our galaxy, the Milky Way. These stars are all gravitationally bound and rotate about a common center. Most have orbits that lie close to the same plane that contains our sun. Looking out through this plane we see projected on the sky the light from those stars in the form of the luminous band we call the Milky Way. (This band is in fact only a part of the galaxy.)

The plane of the Milky Way is home to many objects besides single stars. In addition to our solar system with its swarms of comets, it holds double stars, clusters of stars, tenuous clouds of atomic hydrogen, and dense clouds of molecules containing hydrogen, oxygen, carbon, and other elements, as well as dust. In cocoonlike manner, these dense clouds surround the birthplaces of stars. Also in the plane of the Milky Way are planetary nebulae—the outer envelopes of glowing gas that have been shed by aging stars as they mature—and remnants of supernovae, gas shells, wisps, filaments, neutron stars, and pulsars.

The supernovae are the objects that complete and initiate the life cycles in our galaxy. Having transformed all of the hydrogen and helium in their cores to heavier elements as their fuel, these stars end their lives by exploding and thereby returning to the interstellar medium the elements heavier than the hydrogen and helium from which they formed. New generations of stars, their birth initiated by the compression of the interstellar gases into dense clumps by the shock waves from the supernovae, restart the cosmic life cycle.

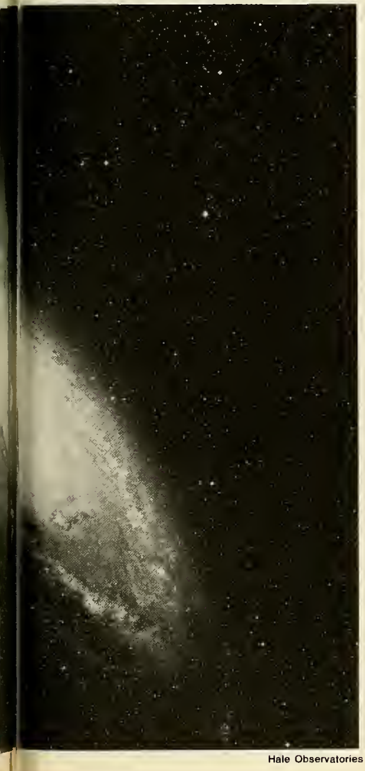
Our galaxy is, of course, not alone in space. There are probably more galaxies in the universe than there are stars in the Milky Way. If you live in the Southern Hemisphere, two satellite galaxies of the Milky Way are a familiar sight in the night sky. They



*The Andromeda galaxy, also known as M31, is a spiral galaxy like our own.*

are the Large and Small Magellanic Clouds (See *Natural History,* June/July 1979), small irregular galaxies gravitationally bound to ours and probably in the process of disruption or perhaps merger with us due to the tidal pull from our greater mass. We know these objects are galaxies because they have the usual galaxy population of stars, star clusters, hydrogen gas, molecules, supernovae remnants, and pulsars.

At distances greater than the Magellanic Clouds, our galactic neighborhood is populated by about twenty known galaxies. These are generally small, globular, and of low mass. Together with our galaxy and the Magellanic Clouds, they constitute an assemblage known as the Local Group. One of our nearest neighbors, the Andromeda galaxy, or M31, and our own galaxy contain most of the mass of the Local Group, and most of the smaller galaxies are clustered within a few million light-years of one of these two large galaxies.

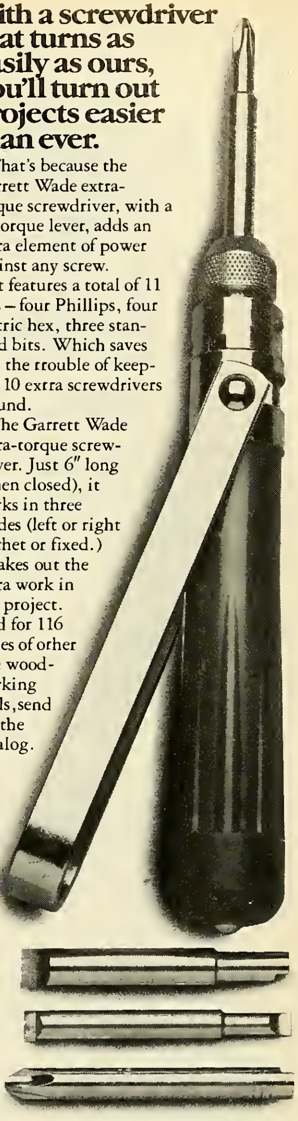


Hale Observatories

Throughout the universe at large, two main classes of galaxies have been identified—spirals and ellipticals. The spiral galaxies, like our galaxy and Andromeda, have their light concentrated to a plane, and their prominent spiral structure is delineated by a population of bright, young, hot massive blue stars and gas. The elliptical galaxies, of either spheroidal or elliptical outline, are devoid of any noticeable structure or gas content. Elliptical galaxies occur in an enormous range of sizes and luminosities, from giant ellipticals in cores of clusters of galaxies, to dwarf ellipticals, often the companions of larger galaxies.

Astronomers have recently established that the morphology of a galaxy is related to its environment. Giant ellipticals are found preferentially in regions of high mass density, such as centers of rich clusters and groups, while spiral galaxies preferentially inhabit lower mass regions, such as the outer parts of clusters, and are isolated in the general field. The density of our own Local Group of galaxies is only slightly enhanced over the average density of galaxies.

What are the mutual motions of galaxies in the Local Group? Although we know very little at present, we do know that M31 and our galaxy are



**With a screwdriver that turns as easily as ours, you'll turn out projects easier than ever.**

That's because the Garrett Wade extra-torque screwdriver, with a 3″ torque lever, adds an extra element of power against any screw.

It features a total of 11 bits – four Phillips, four metric hex, three standard bits. Which saves you the trouble of keeping 10 extra screwdrivers around.

The Garrett Wade extra-torque screwdriver. Just 6″ long (when closed), it works in three modes (left or right ratchet or fixed.) It takes out the extra work in any project. And for 116 pages of other fine woodworking tools, send for the catalog.

Offer expires September 1980

approaching each other. The smaller galaxies are presumed to be in orbit around M31 or around us, moving through circular orbits at great distances or, more likely, through elongated elliptical orbits that take them near our galaxy at their closest approach and to large distances at the most remote part of their orbits. Apparently, the density of matter within the Local Group is sufficient to counteract the expansion of the universe, for there is no evidence that the Local Group is expanding.

The Local Group is one of the outlying aggregates of the Virgo Supercluster, a flattened group of galaxies centered on the Virgo cluster of galaxies at a distance of fifty million light-years from us. Are Supercluster members rotating about the Virgo cluster? Possibly, but probably not. Is the density here sufficient to slow down the expansion of the universe? Possibly. These are difficult questions to answer observationally, and the evidence is still being gathered. Real understanding of these gigantic structures of clusters of galaxies will be fundamental to our understanding the universe.

Beyond the Virgo Supercluster lies the region that Edwin P. Hubble, the American astronomer who studied and classified numerous galaxies beyond the Milky Way, called the Realm of the Nebulae. This region has galaxies in all directions as far as the telescope eye can see—single, double, multiple, clusters, and clusters of clusters. Some galaxies contain as few as one million stars, some as many as a million million. But each one is a dynamical entity held together by the mutual attraction of its stars until approached by a more massive neighbor. When that happens, some galaxies will orbit, some collide, some tear out enormous tails, some lose their outermost stars to the larger galaxy, or—most catastrophic—some will be devoured entirely and form part of a new dynamical entity.

In this garden of galaxies, the internal motions we understand best at present are those of the normal spiral galaxies such as the Milky Way and M31. Our knowledge comes from the study of the spectra of these stellar systems. Although each galaxy is gigantic by terrestrial measuring units, all are so far away that they appear tiny in the sky.

By means of a large telescope and a spectrograph, the light from a galaxy can be dispersed into its component colors (like a rainbow), upon which are superposed bright lines emitted by the excited gas in the galaxy. Because of the systematic internal motions of the stars and gas, these lines are displaced from their normal laboratory position. Light from that part of the galaxy that is rotating away from us is shifted to the red region of the spectrum and light from that part of the galaxy that is turning toward us moves toward the blue. From detailed spectroscopic studies of spirals of various types, a picture has emerged that will fit a spiral galaxy much like our own, one with a radius of about 100,000 light-years, and a mass of about several hundred billion stars.

At the center of such a galaxy is a massive nucleus, whose properties are still somewhat elusive. It could be a black hole, that is, a mass equivalent to some ten million suns in a region as small as a few miles across, or it could be just a giant star cluster of a million stars. Near the center of the galaxy the stellar motions have a circular component, but there are also large-scale structures with motions inward or outward from the center. Energetic phenomena we barely understand are accelerating large masses of material to high velocities, as well as producing radio frequency and X-ray emission.

Beyond a few thousand light-years from the center, the stars and gas settle down to an orderly rotation about the center, with rotational velocities near 300 miles per second. In the solar system, most of the mass is at the center, the sun; and the outer planets therefore move more slowly than the inner ones. In a normal spiral galaxy such as the Milky Way, however, the outer stars orbit with speeds just as great as those of stars near the center. This observation, which came as a surprise, has great implications for the distribution of mass in spiral galaxies and means that most of the mass is not concentrated at the center. In a spiral galaxy, there is significant mass at large distances from the nucleus.

To understand this interpretation, it is necessary to start with the law of gravitation. Newton was the first to understand that the gravitational pull between two objects decreases as the square of the distance between them. If two bodies increase their separation by a factor of two, their mutual attraction goes down by a factor of four. For planets orbiting a sun containing almost all of the solar system mass, this means that outer planets feel a smaller gravitational acceleration, and hence orbit with smaller velocities. Mercury, with a solar distance of 0.39 astronomical units, or AU (an AU equals the distance from the sun to the earth, 93,000,000 miles), moves with a velocity of about thirty miles per second; Pluto, 100 times farther away with a distance of 39.5 AU, moves with a velocity of about three miles per second, only one-tenth that of Mercury.

Astronomers had long expected that in a galaxy, stars at great distances from the nucleus would show low orbital velocities by analogy with the solar system. Thus they were anticipating that most of the mass in a galaxy would be in its nucleus. However, recent observations contradict this expectation. High orbital velocities at large nuclear distances mean that the mass is more uniformly distributed in a galaxy than in a solar system. In fact, for some spiral galaxies, the velocities of stars actually increase the closer they are to the outer edge of the optical image.

This forces us to adopt a new model for the distribution of mass in a spiral galaxy, a model in which the total quantity of matter increases rapidly as the radius increases. Because the mass continues to increase, even at the edge of the optical galaxy, we conclude that there must be significant matter beyond the optical image. It is this unseen mass that keeps the orbital velocities high.

What is the nature of this mass? It cannot be highly luminous or we would see it. It could consist of millions of very faint stars, each with a very low amount of matter, or cool objects that are more planetlike than starlike, or perhaps mini black holes. While the unseen mass might be a flattened disk like the optically visible galaxy, it might, alternatively, envelop the galaxy like a giant halo. How far would such a halo extend? Astronomers are only now attempting to probe such questions using several techniques—observations in the infrared region of the spectrum where cool stars would radiate and observations of rotations in the bulges and halos of distant galaxies. A third method involves the detection of absorption lines from hot gas clouds in the halo of our own galaxy that are superimposed on the spectrum of stars in a neighboring galaxy such as the Magellanic Clouds.

These observations of the outer regions of distant spirals have forced us to reexamine our ideas of the structure of our galaxy. The conventional model of our galaxy places the sun 25,000 light-years from the center, at about two-thirds of the distance to the edge. It also predicts that stars located at greater distances from the center than the sun will orbit with slower velocities.

Prodded by the observations of other galaxies, astronomers have now detected young stars and dust well beyond the solar orbit, whose velocities indicate no decrease in orbital velocity (actually they show a slight increase). Moreover, observations of the hydrogen emission toward the outer edge of the galaxy and of the velocities of the small satellite galaxies at very large nuclear distances suggest that these objects, too, have high orbital velocities in response to the extended mass of our galaxy. There is now every reason to believe that our galaxy has a radius of about 150,000 rather than 50,000 light-years and that the sun is therefore not out in the galactic suburbs.

We do not yet know how far our galaxy extends. An upper limit to its extent must be halfway to the Andromeda galaxy, one million light-years, for if it extended farther, our outer envelope would meet the outer envelope of that galaxy. Theoretical arguments show that two galaxies with interacting envelopes will merge into one composite object in a time as short as the revolution of one galaxy around the other—some hundreds of millions of years. But the presence of so many double galaxies in the universe makes it unlikely that most galaxies have halos extending to their nearest neighbors.

A vast assortment of observational equipment—optical, radio, infrared, X-ray, gamma-ray, and ultraviolet telescopes—is currently being used to investigate galactic structure and dynamics. Progress is rapid in many directions. But as in all good problems, solutions to some parts just raise additional questions to be answered.

*Vera C. Rubin, an astronomer on the staff of the Department of Terrestrial Magnetism at the Carnegie Institution of Washington, specializes in the structure and motion of galaxies.*

### by Herbert R. Harvey

Mexican Masks, by Donald Cordry. *University of Texas Press, $39.95; 280 pp., illus.*

A correlate of modernization in Mexico has been a sharp decline in the production of folk art. Some forms of folk artistic expression have all but disappeared in many localities where, just a few years ago, they were prominent and embedded in the current of daily life. One example is the mask, an important ceremonial accouterment of indigenous Mexico for more than three millenniums.

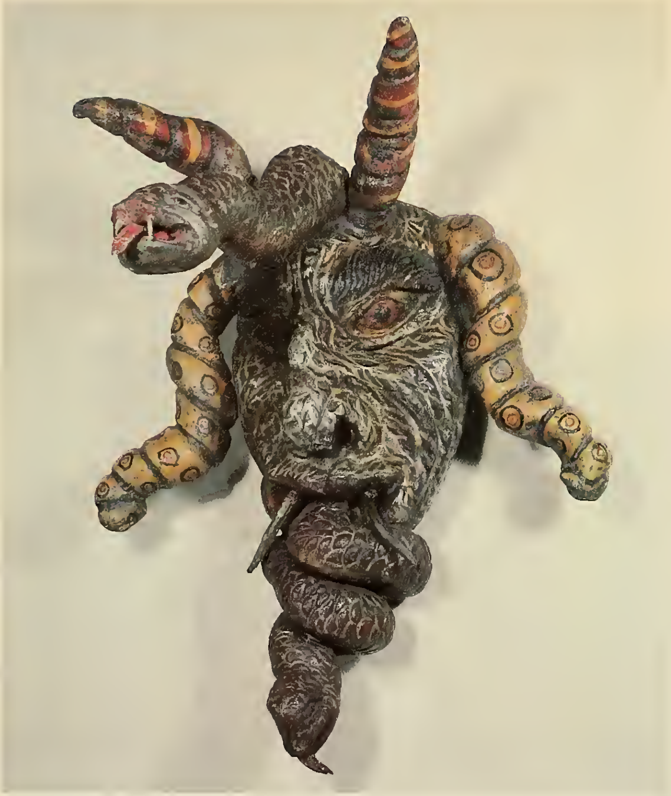
From 1931 until his death in 1978, Donald Cordry, together with his wife, Dorothy, conducted numerous ethnographic investigations throughout Mexico, paying special attention to masks—their use and manufacture, their meaning and significance in the culturally conservative peasant and Indian communities. The results are presented in *Mexican Masks,* the only comprehensive work on this colorful and intriguing expression of Mexican popular art.

This fine volume is beautifully illustrated with more than two hundred color and eighty-five black-and-white photographs, twenty-eight line drawings, and two maps. The majority of photographs are from Cordry's own collection, part of the documentation he built up during forty years of fieldwork. As Peter Furst points out in his introduction to the volume, Cordry possessed the skill of a professional photographer, and his photographs of villages, dances, mask makers, and materials are as important a part of the record as are the field notes and the masks themselves. Without ethnographic context, the masks would lose much of their significance. During field trips, the author systematically collected masks, often under the auspices of such institutions as the Museum of the American Indian and Mexico's National Museum of Anthropology, whose collections he helped to build. At the same time he formed his own private collection, and drew on it extensively for his analysis. It is probably not an exaggeration to say that Donald Cordry had a more profound knowledge of Mexican masks than any other person before or during his time. A successful artist and designer, he brought the sensitivity of his vocation to bear on his avocation.

But *Mexican Masks* is not merely a book of pictures. Rather, it preserves an important balance between descriptive analysis and relevant illustration. The text covers a broad range of subject matter, including the art and iconography of masks, their making and their use. Whenever possible, the author has tried to provide historical context in his discussion. Interestingly, very few masks of great age have survived. In part, this reflects the perishable nature of the materials: paper, wax, leather, even wood. Another reason for the scarcity of old masks is that age alone does not engender reverence for a mask. The lore associated with a particular mask tends not to survive the immediate generations of its maker and owner. Cordry noted that when an old mask occasionally

*Indian soldier mask, Dance of the Battle of the Fifth of May*

*Twin masks, Dance of the Twins*



*Devil mask, dance unknown*

turned up, it often held little meaning for the community or even for those who had kept it in their possession. Thus, many questions about specific masks, such as the origin or intended meaning of a motif or the implication of spatial or temporal stylistic variation, often cannot be answered with any degree of certainty. One of the virtues of the book is that it raises as many provocative questions as it answers and presents a solid point of departure for future research on masks and masked dances.

From the earliest manifestations of civilization in Mesoamerica, masks have played an important role in native religion. There is considerable archeological evidence of their use, and they are depicted in native pictorial codices. Early colonial observers of native culture also made occasional reference to masks. Major pre-Hispanic deities, such as Tlaloc (Lord of the Rain) and Quetzalcoatl-Ehecatl (Lord of the Wind), were depicted as masks. In religious ceremonies, priests serving as masked dancers would become one with the deities whose masks they wore. This transformation was an essential concept in pre-Hispanic religion.

Although it has deep roots in ancient Mexico, modern mask use in ritual performance is also the product of Spanish and, to a lesser extent, African influence. Some aspects of native religion were abhorrent to Spanish missionaries—human sacrifice, for example, and the depiction of Indian deities, who were considered to be demons. But the Spaniards did not suppress the use of masks. On the contrary, they introduced their own masks, reflective of their religious concepts and symbols, which sometimes replaced but more often fused with native ideas. New façades in the guise of Christian personages protected old ideas. Cordry points out, for example, that native deities had both good and bad aspects but that Catholicism tended to concentrate evil in a single personage, the Devil. Indian societies adapted to Spanish imagery by adding horns to their demons. Today devil masks are among the most common and widespread types, but they still often contain iconographic elements common to native cultures. Tigers, butterflies, serpents, frogs, lizards, various birds, and other animal motifs seem more closely linked to native tradition than to external influence.

In general, mask usage today is most prevalent in western Mexico, from the Yaqui and Mayo communities in the northwest, south through the states of Michoacán and Guerrero. But masked dances are also somewhat common in the states of Puebla, Tlaxcala, Oaxaca, and Chiapas. Distribution seems correlated less with linguistic-cultural groupings than with geographical isolation. As the infrastructure of rural roads has increased, masked dances, along with the number of artisans skilled in the craft of mask making, have diminished. Over the decades, Cordry interviewed many mask makers and personally observed the decline in this craft.

Mask makers consist of three types of artisans: the *santero,* who also carves religious statuary; the professional mask maker; and the amateur. To a trained eye, the product of *santeros* can often be distinguished, since *santeros* generally possess more adequate tool kits and greater technical skill. Not surprisingly, there is a tendency for craft production to pass from generation to generation within family lines. The book contains a useful appendix of mask makers, including linguistic and genealogical information, as well as descriptions of tools and mediums customarily used.

There are many and varied ceremonies utilizing masked dancers in traditional Mexican communities. One of the more colorful and widespread groups of masked dances, with roots in sixteenth-century Spanish Catholicism, is that of the Moors (*los Moros*) and Christians. Formerly performed on horseback and often with a large cast of participants, the dance is less pretentious today and is usually performed by a small group of dancers. In this perennial, ritual struggle, a group of dancers representing Christians battle their adversaries, the Moors, until the latter capitulate or are overcome. The dance symbolizes the age-old struggle between Good and Evil, with Good the invariable victor.

Another theme that gained prominence in folk tradition is the Spanish conquest of Mexico. In many of the dances associated with this theme, masked dancers represent such notable figures as Hernán Cortés, the conqueror, and Montezuma, the ill-fated Aztec emperor who lost his life and kingdom in the conquest. Malinche, Cortés's Indian interpreter and mistress, is often portrayed as the betrayer of her people. Such dances recount the destruction of native civilization, a sad event believed to have been redeemed, however, by the advent of Christianity. Other events, such as the Battle of the Fifth of May (1862), have also lingered in folk memory and find occasional expression in dances.

While many dances commemorate identifiable postconquest historical events and Christian personages, others have been performed since antiquity. This is particularly evident in the rain-related group of dances with its propitiation of the Lord of Rain. In a land where drought is an ever present threat to crops, rain-petitioning ceremonies are widespread and their forms and particular modes of expression are rich and varied. Masks used in these ceremonies often contain motifs such as serpents, whose symbolic association with the rain god is of unquestioned antiquity. One of the most fascinating aspects of masks as artistic expression is the variety and manner in which old symbols are interpreted and reinterpreted by mask makers.

Considering the social and technological changes that have taken place in Mexico over the past half century, it would be surprising were they not reflected in the mask tradition. As society has become more secularized, many communities have modified their manner of religious expression. But while some have abandoned their old themes, others have improvised new ones. In addition, regional dances stimulated by government and tourist interest are today more common than in the past, so that the resilient Mexican mask tradition seems to be accommodating itself to a new forum. Future investigators will have a different theater in which to observe the drama, but as it evolves, it may be as rich as the one Cordry found.

NOW BURN COAL EFFICIENTLY TOO!

Choosing next winter's warmth starts now.

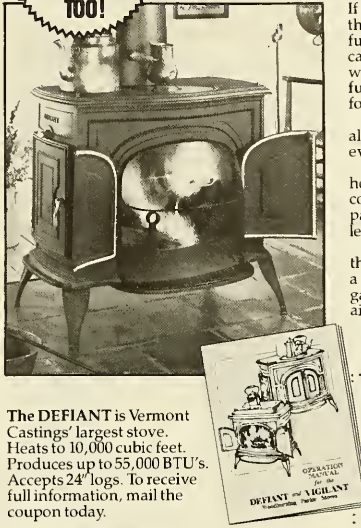
If you've sworn you'll never suffer through another winter of ever-rising fuel bills, take a look at the airtight, all cast iron DEFIANT and VIGILANT—woodstoves as good looking as they are functional. Both offer every requirement for safe, efficient, economical heat:

**Automatic thermostatic control**—allows slow burn for up to 14 hours of even heat on a single loading.

**A unique baffling system**—with preheated air passages and a true secondary combustion chamber, increases flame-path length. The result? More heat from less fuel.

**Converts easily to a fireplace.** With the doors open, enjoy the warmth of a friendly fireplace. Close them, and gain the total efficiency of a superior airtight heater.

Send today for full information, Read it before you buy *any* woodstove. Compare, then decide.



**The DEFIANT** is Vermont Castings' largest stove. Heats to 10,000 cubic feet. Produces up to 55,000 BTU's. Accepts 24" logs. To receive full information, mail the coupon today.

DESMOND MORRIS
ANIMAL DAYS

Illustrated with photos $10.95
*A Perigord Press Book* **William Morrow**
105 Madison Ave., NY, NY 10016

# Additional Reading

**Eskimo Curlew** (p. 30)

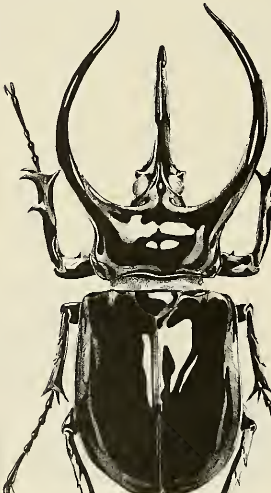
An art book as well as a dependable ornithological reference, *The Shorebirds of North America*, edited by G.D. Stout, with text by P. Matthiessen, paintings by R. V. Clem, and species accounts by R. S. Palmer (New York: Viking Press, 1967), includes information on, and a full-sized color plate of, the Eskimo curlew. A smaller reproduction of this painting can be found in "What to Look For: Eskimo and Little Curlews Compared," by J. Farrand, Jr. This article, along with "Sight Record of Eskimo Curlew (*Numenius borealis*) on West Coast of James Bay, Canada," by J. A. Hagar and K. S. Anderson, and "The Decline and Fall of the Eskimo Curlew, or Why Did the Curlew Go Extaille?" by R. C. Banks, was published in *American Birds* (March 1977). Banks analyzes the decline of the curlew from a new point of view, suggesting that environmental changes contributed more to the curlew's disappearance than previously thought. Two early accounts to which Banks refers are *Life Histories of North American Shore Birds*, by A. C. Bent (*U.S. National Museum Bulletin 146, 1929*), which discusses curlew distribution, biology, and behavior and contains quotes from leading ornithologists of the day, and *The Eskimo Curlew and Its Disappearance*, by M.H. Swenk (*Annual Report of the Smithsonian Institution for the Year Ending June 30, 1915*, pp. 325–40). These reports vehemently claim that overhunting caused the decline of the curlew.

**Horned Beetles** (p.34)

G.J. Arrow of the British Museum (Natural History) devoted his life to the study of beetles, especially horned beetles. His *Horned Beetles* (The Hague: W. Junk, 1951) is a thorough study written for the layman and the scientist. To compare horned beetle behavior and survival with that of other insects, see *Sexual Selection and Reproductive Competition in Insects*, edited by M.S. Blum and N.A. Blum (New York: Academic Press, 1979). *Life on a Little-known Planet*, by H.E. Evans (New York: E.P. Dutton, 1978), is a natural history of insects. In "Horned Beetles," a recent article in *Scientific American* (March 1980, pp. 166–82), W.E. Eberhard explains that beetles use their horns to lift rivals of the same species rather than to stab prey.

**Lakes Baikal and Superior** (p.56)

M. Kozhov's *Lake Baikal and Its Life* (The Hague: W. Junk, 1963), the definitive work on the subject, includes many photographs, tables, and references, briefly reviews the literature about Baikal, and reports on the lake's flora, fauna, geography, and hydrology. Two photographic essays on Baikal and the Siberian countryside are *Ozero Baikal* ("Lake Baikal"), by G.I. Kooka, R. Petera, and E. Varmanyana (Moscow: Soviet Russia Publishers, 1967), and *Vremyena Goda* ("The Four Seasons"), edited by S. Mikhalkov (Moscow: Planeta Publishers, 1978). Lake Baikal has been the subject of magazine articles from time to time—see M.I. Goldman's "The Pollution of Lake Baikal" in the June 19, 1971, issue of *The New Yorker* (pp. 58–66) and R. Chelminski's "Baikal Survives as a Prize for the Whole Planet" (*Smithsonian*, November 1975, pp. 44–51). "Report from Lake Baikal," by S. White (*New Scientist*, August 5, 1976, pp. 275–77), is a status report on pollution in Lake Baikal that includes a special discussion of the Baikalsk cellulose mill. *Lake Baikal Endangered by Pollution*, by P. Nijhoff (*Environmental Conservation*, vol. 6, no. 2, 1979, pp. 111–15), provides an overview. Two large picture books are *Superior: The Haunted Shore*, photographs by B. Litteljohn, text by W. Drew (Toronto: Gage Publishing, 1975), and *The Faces of the Great Lakes*, photographs by B.A. King, text by J. Ela (San Francisco: Sierra Club Books, 1977). The latter illustrates the influence of human activities—cities, industries, fishing, shipping, and mining—on the environment. The story of all the Great Lakes has been told in *The Enduring Great Lakes*, a *Natural History* book edited by J. Rousmaniere (New York: W.W. Norton, 1979).



*Chalcasoma atlas* Daniel Otte

**Urban Plazas** (p.62)

A standard reference for planners, *Death and Life of Great American Cities*, by J. Jacobs (New York: Random House, 1961), was based on direct observations of how people use spaces. J. Jacobs previously contributed a chapter on downtown areas to *Exploding Metropolis*, first published in 1958, by the Editors of Fortune (Westport: Greenwood Press, 1976). In *Personal Space: The Behavioral Basis of Design* (Englewood Cliffs: Prentice-Hall, 1969), R. Sommer discusses human spatial behavior and presents a variety of design concepts for special purposes. E. T. Hall analyzes personal spaces (for example, how close to others people of various cultures can stand without feeling that they are invading another person's privacy) in *The Hidden Dimension* (New York: Doubleday and Co., 1966). In *Streets for People* (New York: Doubleday and Co., 1969), B. Rudofsky speaks unfavorably of American pedestrians. On the other hand, he believes that Italian streets provide many pleasures. For a tour of American cities, see A. Heckscher's *Open Spaces: The Life of American Cities* (New York: Harper and Row, 1978).

**Mississippi Earthquakes** (p. 70)

*The New Madrid Earthquakes of 1811–1812*, by J. Penick, Jr. (Columbia: University of Missouri Press, 1976), a lively account drawn from descriptions published at the time of the quakes, includes woodcuts, maps, sketches, tables, and an eighteen-page guide to further reading. Penick says that "all material relating to the earthquakes that appeared in newspapers from 16 December 1811 through June 1812 is available on a microfiche card attached to Otto W. Nuttli's article, 'The Mississippi Valley Earthquakes of 1811 and 1812: Intensities, Ground Motion and Magnitudes,' *Bulletin of the Seismological Society of America* 63 (February 1973), 227–28." *Continents in Motion: The New Earth Debate*, by W. Sullivan (New York: McGraw-Hill Book Co., 1974), is an introduction to continental drift and plate tectonics. Each chapter has a long list of further references. Earthquakes are among the topics discussed in *Earth*, second edition, by F. Press and R. Siever (San Francisco: W. H. Freeman, 1978). *Continents Adrift and Continents Aground: Readings from Scientific American* (San Francisco: W. H. Freeman and Co., 1976) contains articles by various authors.

*Katharine D'Agosta*

**We've captured fifty of the most fearsome dinosaurs in bronze.**

Only fifty people will have the opportunity to purchase one of these highly collectable, numbered bronzes of Tyrannosaurus rex created by the Tischler Wildlife Studio.

Every detail of this striking work of art has been supervised by Dr. Wann Langston Jr., one of the world's foremost paleontologists. Scale = 1/50th, L= 12".

Every bronze comes with the Hugh Rose Studio's guarantee that it will repurchase your bronze within the first year if you're not completely satisfied. Price: $600.

# Polyester Dinosaurs

Tucked away in the labyrinthine complex of the American Museum of Natural History's twenty-two buildings is a squat, cement-and-brick shed identified simply as the Reproductions Studio. Inside, two staff members and numerous volunteers are busy casting life-sized replicas of some of the massive dinosaur skeletons in the Museum's collection. The skeletons were ordered by various science and natural history museums, which for between $150 and $13,000 will have an exact reproduction of one of the Museum's superb saurian fossils.

The interior of the studio is as remarkable as the outside is dull. The rib cage of a triceratops, huge enough for two people to walk around in, rests on plywood mounts near the entrance. Its freshly cast head sits upside down on a table, and its massive leg bones are stacked like cordwood against the wall. Nearby, technicians are assembling a second triceratops that will eventually be shipped to Saudi Arabia for a multimillion-dollar science and technology museum. Several other unfinished dinosaur skeletons lie in untidy heaps of gray polyester ribs and sections of vertebrae. Other assorted items in various stages of reproduction include fifteen reconstructed heads of prehistoric man, several tracodont (duck-billed) dinosaur skulls, a mold-in-process of the code of Hammurabi, a pile of claw bones, leg bones, foot bones, and rib cages of lycaenops (a mammallike reptile), and several monkey masks from Indonesia.

Martin Cassidy and his assistant, Jeanne Kelly, who operate the studio, are at the top of their highly select profession. Cassidy, with Kelly's help, developed the complex techniques needed to duplicate in plastic the enormous skeletons, although Kelly had not had any formal training in casting before coming to the Museum six years ago.

Cassidy began working in the Museum's Department of Vertebrate Paleontology many years ago, making molds and casts of such things as teeth, small bones, and other fossils for scientific study. "I started experimenting," he says, "using both known and new tooling methods." He spent much of his free time fooling around with molds, with the indulgence of the department. As his techniques became increasingly sophisticated, he was able to cast larger and more complicated skeletons, and other museums began asking for material that was previously unavailable. Finally, the director moved him out of Vertebrate Paleontology and gave him a studio of his own in the Department of Exhibition and Graphics. Shortly after that the Natural History Museum in Osaka, Japan, asked for a complete *Stegosaurus* skeleton, Cassidy's first big job.

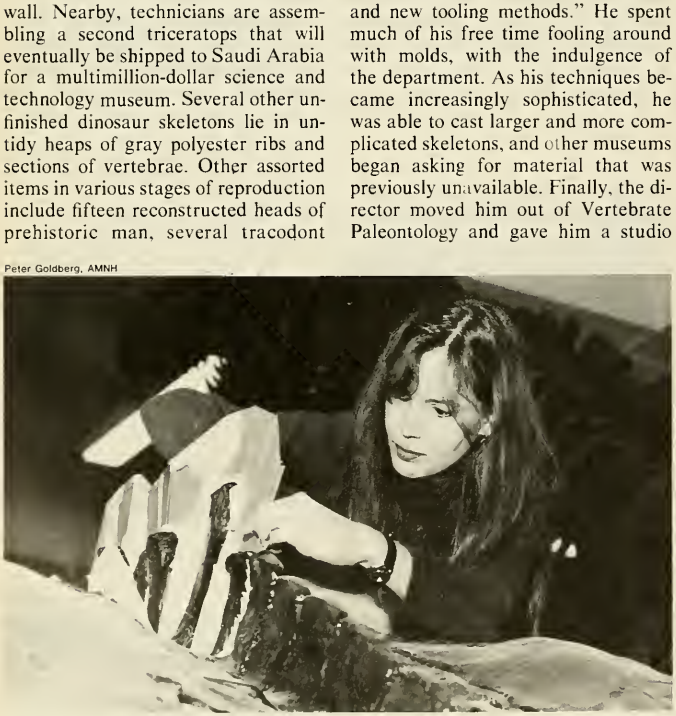
In the field of mold making, which is increasingly reliant on computer technology and the assembly line, Cassidy is a craftsman who knows how to work with his hands. Each skeleton is entirely handmade, and the complex ones may take up to one and a half years to finish. The most sophisticated equipment in the studio is a pair of rebuilt drills that Cassidy picked up on Canal Street for $10. "We try as much as possible," he says, "to modify and adapt existing material and equipment. We mine the Museum's dump for its treasures—scrap metal, wood, packing material. Sometimes just to look at the dump gives us ideas."

The triceratops is their latest skeleton—and their most ambitious. It is more than twenty-three feet long, and its skull alone measures six by four by six feet. The replica required 125 molds, more than 150 gallons of latex, nearly 200 gallons of polyester resin, and in excess of 2,000 hours of work.

Cassidy and Kelly began on the triceratops about two years ago; this summer, they finished two of the four reproductions on order. Their first step was to completely overhaul the skeleton, which had been on display since the 1920s. Because of its weight, all work on the original took place in the Hall of Late Dinosaurs where visitors could watch the action. One side benefit of working in public was that Cassidy drew a steady pool of volunteers from interested spectators, including a Broadway actress, a retired manufacturer of wedding rings, and a talented fourteen-year-old who could roll out a perfectly symmetrical six-foot clay cylinder.

The reproductions team disarticulated parts of the skeleton, repaired damaged areas, cleaned it, and replaced the old plaster reconstructions with fiberglass. Once the triceratops was in top-notch shape, they began marking literally hundreds of reference points on the bones; this information would later appear in the casts.

Peter Goldberg, AMNH



*Working in the Hall of Late Dinosaurs, Jeanne Kelly prepares a backbone section of the massive triceratops skeleton for casting.*

Cassidy also invented and built from scrap wood a contraption he calls a "rib locating and holding jig." The jig, which looks a bit like a porcupine, was built inside the original rib cage and acts as a template for re-creating the exact configuration of the ribs in the duplicate. "That's always the biggest problem," says Cassidy. "We had a hard time with the stegosaurus when we tried operating from photos. The way we've set it up now, anyone could put that skeleton together."

In the next step of casting, they carefully looked at the topology of the bones to decide where each mold should go. Each mold was poured in latex and held in a stiff fiberglass jacket, which reproduced every detail in the original, including the nuts and bolts used to hold the skeleton together. The completed molds were carried back to the studio for casting. A mixture of fiberglass and polyester resin, dyed the approximate color of the original, was used to re-create each bone or grouping of bones. After sanding, staining, and reassembling, the first facsimile was ready for shipment to its new home.

With the growing market for paleontological reproductions, the studio publishes yearly a price list of available casts. The triceratops "ready for mounting" is a mere $13,200. One can also purchase a stegosaurus ($10,450), a four-foot ankylosaurus tail club ($220), a fossil ichthyosaur with young inside ($522), a three-toed merychippus ($1,650), assorted dinosaur footprints ($192.50 and up), and a restored head of Peking man ($137.50). If you don't find what you want on the list, you can always ask. "This is not a commercial operation," says Cassidy. "We offer a service to museums around the world and schedule our prices simply to recover all costs relating to the studio's operation."

To date only museums have ordered skeletons, but Cassidy will sell to anyone willing to put up the money. He would like to see some of New York's downtown office buildings set up some of his castings in their lobbies; they would, after all, be cheaper than most modern sculpture. "There is a lot of interest in these forms as sculpture; bones frequently are a primary metaphor for many artists," he says.

The success of the studio has, of course, been accompanied by a proliferation of molds, which are stored in an adjoining shed. In this unheated space, lit by a single, naked light bulb, negative images of everything from the Aztec Calendar Stone to a *Tyrannosaurus rex* jaw share space with the Museum's snowplow and electric carts. And every year the shelves get more crowded.

A question that both Cassidy and Kelly are often asked is what exactly their job is called. "Paleontological sculptor?" says Kelly. "Too much of a tongue twister. It's hard to say what it is, but I love it." After pausing a few seconds, she adds, "It's what I grew up to be."

*Douglas J. Preston*

**Chinese Puppeteers**

Eleven puppeteers from the People's Republic of China will be giving four performances at the Museum on September 4 through 7 as part of a U.S. tour under the sponsorship of the Asia Society's Performing Arts Program. This troupe performs traditional plays that have been passed down from father to son for generations. The puppets fly through the air, spin plates on their heads, and pour their own cups of tea. The puppets are on tour in the United States for the first time, and this will be their only appearance in New York. For ticket information, write to the Membership Office of the Museum.

**Course for Stargazers**

The Hayden Planetarium offers a wide range of courses on meteorology, astronomy, telescope making, flying, and celestial navigation. A free course catalog and registration form can be obtained by writing to the Hayden Planetarium.

**Grasslands Giant**

*The African Elephant*, a film by naturalist Simon Trevor, will be shown at the August members' program, Wednesday, August 6, at 7:30 P.M. in the Auditorium. The film features scenes of the social behavior, feeding, rearing, mating, and death of the elephant, but it also includes footage of a cheetah stalking its prey, a newborn wildebeest taking its first steps, and flamingos flying over a lake in the Great Rift Valley. The program is free for members, $3.00 for nonmembers.

**Ravi Shankar**

Ravi Shankar, renowned sitarist and composer, will give a lecture-demonstration in the Museum Auditorium on Wednesday, September 10, at 7:00 P.M. Tickets for the evening are $6 ($5 for members) and may be obtained in advance by sending a check to the Department of Education at the Museum.

**Egypt Dances**

A special two-evening series on the dance of Egypt will be presented by the Education Department of the Museum on Wednesday and Thursday, August 20 and 21. Magda Saleh, former prima ballerina with the Cairo Ballet, will introduce and narrate her film, *Egypt Dances*, for the program on Wednesday evening. On Thursday, Walter Terry will comment on three dances that Saleh will perform. Series tickets for the two evenings can be obtained by sending $10 ($8 for members) to the Department of Education at the Museum.

**Museum Highlights Tours**

For veteran museumgoers as well as new visitors, the Museum offers free tours of its most interesting halls and exhibits. The *Museum Highlights Tours* leave on a regular basis from the second floor Information Desk. Check about specific times on the day of your visit.

**Discovery Tours**

The Museum is offering an art and archeology tour of the People's Republic of China in October 1980. Twenty-four participants will join Prof. C. Bruce Hunter for an in-depth visit to archeological and historical sites in Peking, Shanghai, Kwangchow, and other cities. At present, this popular tour is filled, but the Museum is planning similar tours for the spring and fall of 1981. This is just one of the many tours offered by the Museum to its members and friends. For information and itineraries, write to Discovery Tours at the Museum.

# Hot Cajun Sausage

Boudin, *a fiery, pale-colored food speciality, is an important part of Louisiana's Acadian culture*

**by Raymond Sokolov**

Dudley Hebert stirred the big pot with a short-handled canoe paddle, gently prodding thirty-five pounds of pork and pork innards, while they cooked almost to the point of disintegration. Standing in the improvised kitchen at Arceneaux Park in Broussard, Louisiana, some little children and adults watched as he ground that meat and mixed it with rice and lots of red pepper. Then he showed them how to stuff this "rice dressing" into sausage casings. Mr. Hebert and his collaborator, Elmer Girouard, used a hollow, open-ended cow horn to do the stuffing. The horn once belonged to Mr. Girouard's grandfather, who had always used it to stuff sausage on his farm in southwestern Louisiana, when he and his family slaughtered hogs in the preserving cold of a winter day and processed every shred of the animal, from head to hock. Being Cajuns, they spoke French, and called this gala pork butchering event a *boucherie.* And the loose sausage they made—a fiery, pale-colored specialty with a strong taste of liver and kidney—they called *boudin blanc.* Traditional Cajun *boudin blanc* can still be found in Cajun country. Indeed, last February in Broussard, it was impossible to avoid.

Broussard is somewhere in-between being a drab, post-Depression farm center and a suburb of bustling Lafayette, ten miles to the north. This year the Broussard Jaycees and Jaynes sponsored the second annual Louisiana Boudin Festival. Local *boudin* factories worked overtime to produce thousands of pounds of sausages. Hebert and Girouard did their demonstration. Several young men and women competed in the *boudin*-eating contest, slurping stupendous quantities of pork and rice stuffing out of long, drooping casings.

I myself consumed an immoderate number of *boudins,* warding off the chill of an incessant winter drizzle with their warming spices. I ate *boudins* from all the booths, including a seafood *boudin,* heterodox but delicious. Somewhat bloated with all this gorging, I began to see the justice of an opinion expressed by John Norbert, a professional *boudiniste* at one of the booths. "The secret of a good *boudin,*" he averred, "is seasoning plus more meat than rice."

With these words fresh in mind, I joined forces with *boudin* aficionado, Barry Jean Ancelet, a young and impassioned Cajun folklorist at the University of Southwestern Louisiana in Lafayette, who introduced me to the higher arcana of *boudin* at a nearby supermarket called Dud Breaux's. The pork-rice ratio seemed just about ideal as Ancelet, his family, and I worked our way through a few pounds of sausage hot from the pot at Dud Breaux's. We threw the casings to the Ancelet dog and launched into the vexed question of Cajun culture.

The *boudin* is a spongy but natural platform from which to rise to the larger issue of Cajun identity and survival because *boudin*—ungainly, wildly spiced, and messy to eat—has become part of the stereotype of the Cajun in our time.

"Cajun" itself is an emblem of cultural misunderstanding, corrupted from the French *Acadien,* the name given to French settlers driven out of Nova Scotia (then called Acadia) in 1753. As they made their way south, an unfriendly Anglophone North America dubbed them Cajuns. Arriving in southwestern Louisiana's malaria-infested bayous and isolated lowlands about 1765, they found a refuge where they could carry on peacefully as an ignored, French-speaking majority. "They were the melting pot here," says Barry Ancelet. "They were the mainstream society. All through the nineteenth century, other groups came in and adopted French, people with names like Johnson, Segura, and Schneider. The original Cajuns were not immigrants to the United States. They were here before there was a United States. My grandmother objected when a nephew of hers married *'une americaine.'*

"As late as the turn of the century, Cajun culture was all there was around here. Hell, everyone was eating *boudin.* Then the Anglo-American world began to press in. Oil was found in Jennings, at the so-called Evangeline field. (I really resent the whole Evangeline business, having the rest of the world learn about us through that poem. Longfellow never met a Cajun. And he wrote in English.) Oil brought in a money economy and an English-speaking population. Then the mandatory education act established a school

system that forced our kids to learn English. And World War I took a whole generation of Cajuns away from home, where they saw for the first time that they were a minority. The mass media finished the job of putting our culture in danger, by providing slick programming that was much better than anything coming from here. People began to feel their culture was low class, something to leave behind."

With all these external pressures on them, it was no wonder that many Cajuns fled into assimilation or as far away as they could from the traditional life of the Cajun "coonass," a local pejorative probably drawn from the French slang term *conasse*, meaning a stupid person or, as Vaughan Burdin Baker puts it in the Junior League of Lafayette's Cajun cookbook, *Talk About Good,* "an ignorant and superstitious individual speaking ungrammatical and thickly accented English, eating *boudin* and two-stepping to a cacophonous accordion."

Currently, Ancelet estimates that there are about one million French-speaking people in Louisiana, of whom only one-third to one-half use French primarily. This is a sharp decline from the 100 percent of a few decades ago. But there are counterforces at work. Cajun music has undergone a serious revival. French, albeit standard French, is now promoted officially in local schools. And the University of Southwestern Louisiana fosters Cajun traditions through the Center for Acadian and Creole Folklore, which employs Barry Ancelet, who is militantly at work trying to foment a literary and cultural renaissance conducted in the dialect of his forebears.

Food plays no small part in Ancelet's plans. Cajun food is especially threatened by outside influences. The homogenizing forces of American agriculture and corporate food production compete with Cajun rural cuisine, just as they do with every American food tradition rooted in the folkways of oldtime farm life. In a world of supermarket meat departments, the Cajun *boucherie*, once a focal point of Cajun communal existence, now happens only here and there, and just rarely enough so that people turn out for a staged hog slaughtering just as they would for a special event.

Perhaps the Louisiana Boudin Festival itself is a sign of incipient decline. No figures exist for comparing *boudin* consumption today with its consumption fifty years ago. But it is safe to say that *boudin*, more than any other feature of Cajun life, apart from the French language, symbolizes the French-speaking community of Louisiana and its complicated, imperiled identity. When you taste a *boudin*

photographs by Adelaide de Menil

*A sausage-stuffing machine with stringlike hog casing attached to its nozzle; the casing is long and part has already been filled with* boudin blanc.

*blanc,* you know you have come into contact with Cajun culture, unapologetic and unlike anything else.

Well, not quite. Like Cajun French, the Cajun *boudin* has firm roots in France. The heavy amount of rice in the stuffing reflects the overwhelming traditional local commitment to rice as a crop, and the powerful spice in the Cajun *boudin* may bring tears to the eyes of French visitors; but those same visitors can undoubtedly lay claim to a paler but older recipe for a recognizably similar *boudin blanc.*

Indeed, the roots of the *boudin* go very deep, right to the bedrock of European civilization. The etymology of the word is not altogether certain, but it probably derives from a Latin word for sausage, *botulus*. The philosopher Seneca speaks, in a letter, of a *botularius,* a "sausage seller." And our word *botulism* is the name of a lethal disease first demonstrably caused by infected sausages.

*The Larousse Gastronomique,* with its usual certitude, declares that the *boudin* is a sausage consisting of a hog's large intestine filled with hog's blood. In English, we would call this concoction (which *Larousse* fancifully ascribes to the cuisine of ancient Assyria) a blood pudding.

It takes no great leap of phonological imagination to see the bond between *pudding* and *boudin.* They sound somewhat alike, and they both originally referred to sausages that had to be cooked so that their stuffing would solidify and become edible. Our modern sense of pudding developed because dessert puddings used to be boiled in casinglike bags. In England, the practice still continues.

In France (which somewhat later received the word *pouding* as a loan from England to describe molded desserts such as English plum pudding) *boudin* retained its original sense of blood sausage, but extended it to include a sausage of minced pork meat mixed with egg and cream, then poached until the eggs firmed up the stuffing. This is the most probable ancestor of the Cajuns' *boudin blanc.*

But if Cajuns carry on this secondary tradition of white *boudin,* what happened to the primary one, the pseudo-Assyrian blood pudding still so popular in modern France when grilled and accompanied with sautéed apple rings or mashed potatoes? Barry Ancelet thought the Cajun version of this, called *boudin rouge*, had died out completely. But at least one enterprising food retailer, LeBouef's of Broussard, still produces Cajun blood pudding on a daily basis in a sausage factory tucked away behind a big conventional American supermarket.

The LeBouef family opened shop many years ago as a *boudin* and crackling store. The current Mrs. LeBouef's grandmother made the sausage at home. Today, the LeBouefs have their own abattoir a short drive from the market, where they slaughter all kinds of meat for their butcher department. And so they are in a position to collect fresh blood legally for *boudin rouge.* Pork blood is too hard to keep free from hairs, so they use veal blood; this satisfies the meat inspector but isn't, in theory, as tasty.

On a typical day at the *boudin* factory behind LeBouef's supermarket, Jacques Benjamin, a French-speaking black, finished up his day's work on several hundred pounds of white *boudin* and turned his attention to the red. Wearing an orange apron, he poured two gallons of blood and cooked rice and seasonings, pork fat, and a scoopful of cayenne into his sausage-stuffing machine. The little room was filled with a haze of red pepper. Tripping the motor switch, he babied a casing as it filled and turned dark purple. He knotted and twisted it into a string of resilient sausages and then started another casing. Eventually, he completed the batch and put it in a pot of water to poach for a half hour, testing for doneness by poking through the skins with a toothpick. By the time he was done, a crowd of workmen and truck drivers were lined up outside at the meat counter to buy their lunch. Hot *boudin blanc,* hot *boudin rouge.* Hot enough to make a Frenchman cry. Hot enough to make a Cajun weep for joy. (See recipe on page 96.)

*Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.*

*Jacques Benjamin adds a scoopful of cayenne pepper to* boudin *stuffing.*

*In preparing* boudin rouge, *casing ends are twisted and knotted to form individual sausages.*

## Cajun Boudin Blanc

2½ pounds boneless fresh pork, butt, or shoulder
¾ pound pork liver
¼ pound pork kidney
Salt
2 cups long-grain white rice
2 tablespoons butter
1 large onion, peeled and coarsely chopped
2 bunches scallions, chopped
1 handful parsley
Black pepper
2 teaspoons cayenne pepper
3 yards small sausage casing, approximately (see note)

1. Cook pork, pork liver, and pork kidney in lightly salted boiling water to cover until meat falls apart, about 2 hours. Reserve the meats and the broth.
2. Meanwhile combine rice, butter, 2 teaspoons salt, and 4 cups of water in a heavy saucepan. Bring to a boil, stir once, cover, reduce heat to low, and cook for 15 minutes. Empty rice into a bowl and reserve.
3. Grind the reserved meats, onion, scallions, and parsley together in a meat grinder, using the coarse blade, or grind coarsely in a processor, using the metal blade.
4. Mix the ground meat mixture with the rice, black pepper to taste, salt to taste, and the cayenne pepper. Add the cayenne gradually. The amount recommended may be impractically torrid for non-Cajuns, although it is ethnographically correct.
5. Mix in enough of the reserved broth to make the stuffing moist but not soggy.
6. Rinse the casings to leach out the salt they are preserved in. Cut them into 20-inch lengths with a scissors.
7. If you have a traditional metal sausage-stuffing "horn" or an attachment for a mixer or meat grinder, any one of them will work well for this recipe. Even a large household funnel will suffice. Work one end of the casing over the tube. Then pull on the rest of the casing in a series of folds. It is not necessary to knot the casing. Merely press the free end of the casing and pull it an inch or so off the tube. Then push the stuffing through the tube into the casing, which with some assistance from you, will pull off the tube as it fills. When the casing is filled (with an inch of free space at either end), twist the ends and set aside. Continue until all stuffing is used up. Prick the casings here and there to release any trapped air. The filling is dense enough so that only minor amounts of filling, if any at all, will leak out during the final cooking.
8. *Boudins blancs* are usually served steamed. In other words, heat up a batch in barely simmering water and serve. Eat them by holding the casing in your hands and sucking the insides from the casing. Discard emptied casings.

Yield: About 8 servings

BOUDIN
FESTIVAL
Broussard
Savoys

Note: For $10 postpaid, casings are available from Standard Casings, 121 Spring St., New York, N.Y. 10012, in 100-yard hanks that keep almost indefinitely under refrigeration. Paprikas Weiss, 1546 Second Ave., New York, N.Y. 10028, will mail syringe-like sausage horns for $35.00 postpaid.

**Why we take care of our trees.**

If you were a farmer whose only crop had a 50 year growing cycle, you'd take very good care of it, right? Well, we are that farmer. Our crop takes 50 years, on average, to reach maturity.

That's why we plant five seedlings for every tree we harvest, why we feed them, prune them, thin them, protect them from insects, disease and fire.

That's why we continually explore new forest management techniques that promise more trees per acre, and new manufacturing processes that promise more wood and paper per tree.

That's why we increasingly use what once was wasted, either to make products like yeast, chunk bark and particleboard, or to generate energy.

It's a matter of self-interest, finally. Only by managing our trees prudently can we provide the jobs, products and profits we all need and the forests we all love.

**Boise Cascade Corporation**
Wood and paper for today, trees for tomorrow.

# Build your own private library for less than $20 a month!

*Each volume bound in genuine leather and fine fabric . . . the leather embellished with 22 karat gold.*

Imagine being able to glance up at your bookshelf, and see there your own private library. With its proud expanse of leather spines, bearing the titles of the greatest books ever written.

Here, clearly, would be something of permanence in a changing and uncertain world. Something to treasure now . . . and to pass along to future generations in years to come.

A treasure, indeed, you might think—but surely an expensive luxury. *Far from it.*

For this is The Heirloom Library of the World's Greatest Books. Fifty enduring works of genius, selected by a distinguished board of advisers. In the handsome Collector's Edition, crafted for posterity in bindings of genuine leather and fine fabrics. Ornamented with exclusive designs, the spines embellished with 22 karat gold.

**Beautiful books, at a guaranteed low price—yet you make no long-term commitment**

The Collector's Edition of the Heirloom Library will be issued at the convenient rate of one great book per month, for just $19.50 a volume—a price *guaranteed* for the duration of your subscription. However, *you* need make no long-term commitment. You may cancel your subscription at any time, on 30 days' written notice.

**The rare pleasures of owning this personal library**

As a subscriber, you would enjoy, whenever you wish, the rich pleasure of taking one of these books from your shelf—with its fragrance of leather, its satisfying weight in your hands. Then savor a moment of anticipation as you open the volume, to see your own inscribed bookplate on the decorated endpapers. And leaf through the pages admiring the burnished edges . . . the smooth, opaque paper . . . the crisp, legible type . . . the wonderfully evocative illustrations.

Above all, you would be able to enter at will . . . as one embarking on voyage of discovery . . . the world of Hemingway or Melville, Shakespeare or Dante, Dickens or Mark Twain. The greatest books ever written, in bindings worthy of the incomparable works they contain.

**Mail your order by September 30th**

By the time your library is complete, even ordinary books may be selling fo more than $19.50. For the costs of materials, of printing and binding, are rising almost daily. And thus it may *never again* be possible to offer subscriptions to the Collector's Editio of the Heirloom Library at this guaranteed low price. *So, to be sure of acquiring this remarkable private librar for no more than $19.50 a volume, mail the subscription form at right by September 30, 1980.*

DIVINE COMEDY
DANTE ALIGHIERI

*In a time-honored collecting tradition . . . the greatest books of the greatest writers of all time. Bound in genuine leather and fine fabrics. Leather embellished with 22 karat gold.*

With this $25 rebate, Minolta's most economical compact SLR is now even more economical. So it's an incredible value. Because it has a remarkable combination of features found in no other camera in its class.

It's easy to get clear, sharp pictures with the XG-1 because it's a fully automatic 35mm camera that sets itself electronically. It also gives you manual over-ride, an LED shutter-speed display in the viewfinder, and an automatic shutter-lock to prevent over-exposed pictures.

The XG-1 accepts more than 40 interchangeable Minolta lenses and optional accessories like an auto winder and electronic flash.

Talk to your Minolta dealer today for details about the XG-1 rebate from Minolta. But hurry. This is a limited offer.

**$25 REBATE**

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE WITH A MINOLTA XG-1.

"I became interested in the behavior of the pygmy chimpanzee," says **Randall Susman,** "as a result of studies that showed their anatomy to be different from that of their close relative, the so-called common chimpanzee. I wanted to find a behavioral explanation for the observed anatomical differences." Susman did his chimpanzee fieldwork in Zaire. Other research that engages his attention includes the functional and comparative anatomy of apes and humans, experimental studies of ape locomotion, and the anatomy of fossil humans. An assistant professor of anatomy, Susman is a member of the primatology research group in the Department of Anatomical Sciences at SUNY, Stony Brook, N.Y. He received his Ph.D. in anthropology from the University of Chicago in 1976.

On a raft trip down the Colorado River in 1969, **Jim I. Mead** met Paul S. Martin of the University of Arizona, who introduced him to the study of fossils in the Grand Canyon and their use in reconstructing past environments. Mead went on to excavate numerous caves in the canyon, with a particular emphasis on fossil pack rat middens. Analyses of these remains have provided a much clearer picture of the Grand Canyon's faunal and floral history than previously existed. Mead, a Ph.D. candidate in geosciences at the University of Arizona, is now searching caves in the Grand Canyon area for remains of the extinct Harrington's mountain goat. In his spare time, he collects mammal and reptile skeletons to add to his comparative osteological collection.

# ESCAPADE ECUATORIANA

## TOURS TO SOUTH AMERICA

## The wonders and beauty of all the Americas are yours.

Come to our Andes. Come to our Amazon. Come to our America. We've found the most exciting ways through our mysterious jungles, soaring mountains and fabulous cities. We know where nature is perfectly preserved. And we can show you the most relaxing beaches and exciting nightlife. And hotels and restaurants that are always superb. All through Ecuador. And all through South America.

Call toll-free 800-327-1337
1-800-432-1372 in Florida only.

### Let our Escapade Ecuatoriana tours show you our America:

**1. Indian Culture Tours.**
The trail to Machu-Picchu is only one of the paths to Indian and jungle life you can explore.

**2. The Living Amazon.**
The mightiest river in South America reveals its secrets of primitive culture and untamed nature.

**3. Cities of South America.**
Take your pick of the most exciting and beautiful cities in all the Americas.

**4. Galapagos. Islands of natural wonders.**
Visit the enchanted islands where the exotic wildlife sparked Darwin's theories.

We can help you select just the right South American Escapade Ecuatoriana tour. For expert advice, please see your Travel Agent.

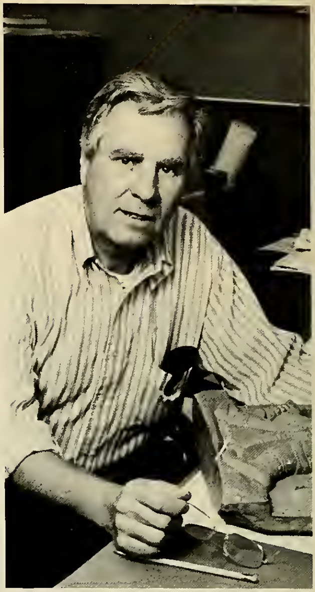
WESO Ceramic Tile Stove
The elegant, efficient alternative to metal

No metal stove can approach the ability of European *kachelofens* to capture, store and release heat from a brisk fire. The WESO combines the heat-storage principles of these classic tile stoves with modern combustion technology; its breathtaking beauty conceals probably the most efficient stove burning wood or coal you can buy:

☐ True *kachelofen* heat, mild yet penetrating, that no metal stove can match ☐ Safer to use, safe to touch ☐ Heats by natural convection and radiant warmth for more even temperatures floor to ceiling ☐ Pull-out ash pan — No scraping, no ash mess! ☐ Holds a fire to 12 hours ☐ Automatic thermostat ☐ Preheated air inflow ☐ You see the fire flickering behind the front grille ☐ Top grille lifts for cooking ☐ Choice of tile colors in lustrous or satin glaze.

Kachelofen.
Start planning for next winter now!
Send $1 for portfolio of brochures with tile colors
Ceramic Radiant Heat
2909 Pleasant Dr., Lochmere, N.H. 03252 (603) 524-9663

"My maternal grandfather was an importer and lived for a time in China. The house I grew up in was always filled with Asian objects and that may account for my lifetime interest in Asia and the Near East," says **Walter A. Fairservis, Jr.** An archeologist and anthropologist, who teaches at Vassar College and is concurrently a research associate at the American Museum of Natural History, Fairservis made his first field trip at the age of 16, when he ran away from school to see Egypt and India. He joined the American Museum initially as a volunteer in 1941. Among the many expeditions he has led for the Museum since then were several to Afghanistan and Pakistan, and later to Egypt. Fairservis is the scientific consultant for the Museum's new Gardner D. Stout Hall of Asian Peoples. He has written several books and many journal articles on anthropology and Old World archeology.



From the time he was a teenager, **Lee Boltin** knew that he wanted to be a photographer. He developed his art in the Photography Department of the American Museum of Natural History, where he stayed for twelve years. In 1955 he left the Museum to free-lance as a photographer of art objects, working in museums and with private collections. His speciality has been a passport that has taken him around the world and given him access to the treasures of museums in at least fifteen different countries. Boltin has illustrated about 25 or 30 books and catalogs. Among recently issued volumes using his photographs are *The Nelson A. Rockefeller Collection, Masterpieces of Primitive Art* (1978) and *Gold of El Dorado* (1979). Boltin's photographs will also appear in an as yet untitled book, based on the late Nelson Rockefeller's private collection of twentieth-century art.

# Now-A Record Club With No Obligation!

# Choose Any 3 or 4 Record Set

## For Only $2.98

FELIX MENDELSSOHN BARTHOLDY

**Also Available On Cassette**

## No obligation to buy any future offerings.

This remarkable $2.98 offer is brought to you by The International Preview Society—a highly selective music program that does not oblige you to buy at any time. These multi-record/cassette selections—and many, many more superb choices will continue to be offered in an exclusive Preview magazine approximately every seven weeks. Each issue highlights a Featured Selection . . . plus an impressive variety of alternate selections (many available on cassettes). And all are well below suggested retail!

You'll save even more through *the Society's Half-Price Bonus Plan*. For every regular member purchase you make, you may choose a Bonus—album or multi-record set—for only *half* of the members' already-low club price. *That amounts to a savings of more than 55% off the suggested retail price!*

If you'd like to preview the Featured Selection, you need do nothing. We'll send it automatically. But if you'd prefer an alternate selection or none at all, just mail back the Preview Notification card—enclosed with the magazine—by the specified date. You'll have plenty of advance notice.

**Audition Any Selection At Home For Ten Days . . . Free.**

At no cost or obligation, you are invited to audition any one of these multi-record albums . . . as well as any future offerings . . . at home for ten days. Only then do you decide whether or not to buy.

**As Many As Four Records For Less Than The Price Of One.**

You may choose any one of these sets for just $2.98 plus a small postage/handling charge. (Sales tax added for New York residents.) Remember, each set contains either three or four records (or 2 to 4 cassettes). That's a savings of as much as $36.94 . . . up to 92% off the suggested list price!

Send no money. We want you to judge for yourself before you decide to buy. If you are not delighted after ten days, return the set.

These are superior, silent-surfaced recordings by Deutsche Grammophon and Philips. They come in a handsome storage case with an informative, illustrated brochure.

Every recording offered by the Society must meet the rigid standards of The Carnegie Hall Selection Committee. Only albums of the most exceptional musical interest, artistic excellence and technical quality are offered.

So do take advantage of this marvelous value and mail in the coupon today. You'll also be reserving the privilege of previewing other great international releases . . . which you may add to your collection at impressive savings.

## A Night in the Day of a Pest-Control Researcher

Stephen C. Frantz

Stephen C. Frantz's article "Rats in the Granary" (February 1976) grew out of his research in India where he spent his nights in warehouses, letting the lesser bandicoot rats he was studying climb over his lap on their way to the rice. Frantz has stuck with rats, but he is now director of the New York State Health Department's Rodent Control Evaluation Laboratory in Troy, N.Y. The laboratory's primary work is studying the genetic resistance of rats to certain kinds of rodenticides. Frantz has not entirely abandoned nocturnal adventures, however. Last summer he began a study of garbage.

The way garbage is handled is of prime concern in any kind of pest control because garbage is such an important food source for pests. Frantz wanted to find out when people put out their garbage, how much they put out, what they put it in, and how garbage collectors handle it. He and his coworkers began observing and interviewing garbage collectors, going out at night to observe people putting their garbage out, and surreptitiously weighing the garbage.

For this last task, a group of researchers wearing white suits would go out in an unmarked van between midnight and 5:00 A.M., pull up in front of a house or apartment building, take all the garbage, weigh it in the van, and then put it back. The group was on occasion bothered by the police and suffered the shouts and yells of a few outraged garbage owners, but at least, says Frantz, "nobody shot at us." The garbage study is still under way, and one of the probable next steps is a qualitative analysis of the garbage, not how much, but *what* people throw out.

## Panhandling Bears of the Smokies

Why do bears panhandle food from tourists? Because the technique works. In fact, bears, or at least black bears in Great Smoky Mountains National Park, have a success rate that puts human panhandlers to shame. Michael R. Pelton, who wrote "Black Bears of the Smokies" with Gordon M. Burghardt (January 1976), went on to direct a three-year study of panhandling bears and found that in 301 sessions, involving 33 different bears and countless tourists, the bears never went away empty-pawed.

Supervised by Pelton, the study was carried out by Jane Tate, one of his graduate students in the ecology program of the University of Tennessee's Department of Forestry, Wildlife and Fisheries. For three summers (1976–78) Tate observed, filmed, videotaped, and photographed human–bear interactions along a main road that runs through the park. The picture that emerged showed that there were eleven "professional" panhandling bears seen in more than fifteen sessions and

## with matching snap case for only $3.95

(published at $19.90)

You'd never expect bird guides to show up on **The New York Times** best seller list. Yet these did, for many weeks. Perhaps because they're so beautiful, so useful. And absolutely unique, in two essential ways.

Ordinary guides arrange birds by ornithological family. Without prior knowledge of bird families and species, you're left pretty much in the dark when it comes to identification. But these Audubon Society Guides arrange bird pictures in groups by **appearance.** So you simply check what you've seen—and find your bird **fast.**

Another thing. These are the **first** and **only** guides to show birds in superb full-color photographs rather than conventional paintings. The camera sees exactly what you would see in the field: the natural color and stance of the bird in its natural habitat. You'll find a total of 1,211 spectacular full-color photographs in the two volumes, and they make identification wonderfully easy. But even if you never go birdwatching, these books are destined to be among the most treasured in your nature library.

**Enjoy Substantial Savings.** The two Audubon Society North American Bird Guides were published at $19.90. Yet both—with matching snap case—are now yours for only $3.95, to introduce you to Nature Book Club. As a member, you'll be offered a varied selection of important new books covering all aspects of nature: animals, birds, plants, fish, minerals, wilderness places, camping, exploration, natural history, science—intriguing subjects of timely and enduring interest...colorful, informative books you'll turn to again and again, and be proud to own.

Nature Book Club offerings are comparable in every way—paper, printing, binding, jacket—to the original publishers' editions yet members may save up to 50% and sometimes more on hundreds of bargains offered each year in the Club. So join us now while this generous introductory offer is still in effect. **Mail the postpaid card today!**

SEND NO MONEY NOW. To receive your 2-volume Audubon Society Bird Guide set with matching snap case, mail postage-paid card today. If card is missing, write to: NATURE BOOK CLUB, P.O. Box 2026, Latham, N.Y. 12111.

In the months ahead, you'll be offered a choice of fine nature books like these ——many at member discounts as high as 50% (sometimes more).

**How your Club membership works:** About every four weeks (14 times a year) you will receive a Club bulletin describing the main selection and alternate books also available. If you want the main selection only, you need do nothing—it will be sent to you automatically. If you don't want the main selection or want alternate books, or no books at all, simply indicate your wishes on the form that comes with the bulletin and return it by the date specified. Club mailings are carefully scheduled to assure you of at least 10 days in which to do this. But in the unlikely event that you don't have 10 days, and you receive an unwanted selection, you may return it at our expense. Your only obligation is to buy just two more books of your choice within the coming year. After that, membership may be canceled by either you or the Club. What a great way to build a valuable library of marvelous nature books at big bargains.

Speak German like a Diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign service personnel, that's who.

Now *you* can make a start on learning to speak German with the same materials used by the U.S. Department of State — the Foreign Service Institute's *Programmed introduction to German* and *Basic Course, Continued.*

The FSI spent thousands of dollars and many years developing these materials for use by members of America's diplomatic corps. Today people in all walks of life who need to learn to speak a foreign language are turning to this outstanding audio cassette program.

The Foreign Service Institute's German Course is by far the most effective way to learn German at your convenience and at your own pace. It consists of a series of tape cassettes and accompanying textbook. You simply follow the spoken and written instructions, listening and learning. By the end of the course you'll find yourself learning and speaking entirely in German! A native German speaker, clearly recorded on the cassettes, provides an excellent model to help you develop your skills.

*This course turns your cassette player into a "teaching machine."* With its unique "programmed" learning method, you set your own pace testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes: You may order one or both courses:

- ☐ **Volume I. Programmed introduction to German,** 9 cassettes, 12 hours and 647-page text, $115.
- ☐ **Volume II. Basic Course, Continued (More Advanced)** 8 cassettes, 8½ hours and a 333-page text, $98.

(New York State residents add appropriate sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's German course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the most convenient and most painless way to learn German, return it and we'll refund every penny you paid! Order today!

Enter the world of original art for 15¢.

For 15¢, you can mail this coupon to Europe's leaders in original prints, Christie's Print Collection. You will receive a colour portfolio containing our latest selection of original lithographs and etchings.

We offer beautiful landscapes and figurative works by rising young artists from $100 to $150. As well as the work of such masters as Chagall, Moore and Miro.

Each work is an original, numbered and signed by the artist. Then it is stamped with Christie's seal of authentication and delivered to your home.

There is no better way to buy original prints. No better time than now.

twenty-two occasional beggars that appeared in less than fifteen sessions. (A session sometimes involved more than one bear.)

The bears were more aggressive than human panhandlers. In 44 percent of the sessions a bear exhibited what the observers considered an aggressive act—anything from a low moan to a charge complete with biting and scratching. But the bears did not seem to have any serious damage in mind. Of 624 acts of aggression (some sessions included more than one act), only 37 resulted in physical contact between a bear and a person, and the bear's bites and scratches broke the skin in a third of those cases. There were no serious injuries.

In some cases the bears showed astonishing restraint. One bear being pestered by two teen-age boys, creatures known to test the limits of human patience, grabbed one of the boys from behind, held him in a classic "bear hug" with its jaws around his neck and then threw him to the ground. When the observers ran to his side, says Pelton, they found "there wasn't a scratch on him."

The information gathered by Tate was presented to the National Park Service in a preliminary report designed to provide information for educating tourists in their dealings with bears. The humans, says Pelton, invariably provoke the bears' aggressive actions. First of all, it is illegal to feed the bears, an injunction that is universally disregarded. Beyond that, in 80 percent of the cases where bears reacted aggressively, their reaction was preceded by people petting them, crowding them, or petting and crowding them at the same time. The tourists, however, generally blamed the incidents on the bears.

Pelton did not speculate on what the bears' reactions might be if their panhandling failed.

## P.P.S.

In a May "Postscripts" item on electric currents in lampreys, Lionel F. Jaffe was incorrectly described as being at Yale University. Jaffe is at Purdue University in Indiana. The two other researchers involved in the lamprey work (who are from Yale) traveled to Purdue to conduct experiments in Jaffe's laboratory, using equipment that he developed.

# The Dreyfus Rainbow

## A unique variable annuity with money market yields, tax deferred

### Announcing a new and unique way to defer taxes on today's high yields

Ease the inflation/tax squeeze on investment income. Through tax deferred income, The Dreyfus Rainbow lets you provide for retirement and other long-range goals.*

### Minimum just $1,500–
### No sales charge

If you already have shares in Dreyfus Liquid Assets, a high yielding money market fund, you can transfer them to The Dreyfus Rainbow without any exchange charge.

### No surrender charge

There's no charge for withdrawal of all or any part of your funds. Occasional withdrawals are free of federal taxes until they exceed the total amount paid in.

### A choice of payout options

The Dreyfus Rainbow is flexible and lets you choose among several long-range payout options, including options for annuity income which you cannot outlive. Whatever option you choose now can be changed later. To learn more, send the coupon or call today!†

The Dreyfus Rainbow is a variable annuity contract (Form 8-750) issued by The Dreyfus Rainbow Annuity Variable Account A, a segregated asset account of Beneficial National Life Insurance Company, 2 Park Avenue, New York, N.Y. 10016. The Dreyfus Rainbow is filed in all fifty states, but may not yet be effective in some states.

# Vision with a Vengeance

*Most efforts to place ourselves within or outside of nature have been fruitless*

**by Stephen Jay Gould**

When Linnaeus sought to classify all of life in 1758, he called his great work the *Systema Naturae*, the "System of Nature." Biologists of all subsequent generations have flooded the scientific literature with alternative, but equally comprehensive, systems. The content changes, but the passion for building systems remains. Our urge to make sense of the complexity that surrounds us, to put it *all* together, overwhelms our natural caution before such a daunting task.

A curious irony infects this tradition of building comprehensive systems in biology. Biologists present their systems either as necessary truths of superior logic or as ineluctable conclusions drawn from unrivaled powers of observation—in other words, as objective renderings of nature, heretofore unappreciated. In fact, these systems share only one common property—and it is neither objectivity nor superior wisdom. They are, at base, attempts to resolve a (perhaps *the*) cardinal question of intellectual history: What is the role and status of our own species, *Homo sapiens*, in nature and the cosmos?

Systems follow one of two strategies in their attempt to make sense of "man's place in nature," to use T.H. Huxley's phrase. I wrote about one strategy—the picket fence—in my column of February 1980. Such systems devise a pervasive order for the rest of nature, but separate humans alone with a brand of superiority. Thus, Charles Lyell envisaged a world ever churning and changing, but always remaining the same—replacement without improvement. Only man, a recent imposition of moral perfection upon a stable world, broke the pattern of change without progress. A.R. Wallace attributed all features of organisms to the molding power of natural selection—except for one product of divine inspiration: the human brain.

The second strategy in pursuit of the same goal takes an opposite tack, a placement within nature that will make some sense of our lives. This strategy argues for no separation between man and nature at all. These theories of continuity can proceed in either direction, and I shall discuss one recent example of each as representatives of a long tradition of flawed argument. The first view—I shall call it zoocentric—builds general principles from the behavior of other animals and then subsumes humans completely into the rubric because we are, after all and undeniably, animals too. The second view—I shall call it anthropocentric—tries to subsume nature in us by viewing our peculiarities as the goal of life from the start.

Evolutionary theory itself has an appropriately zoocentric core. General principles cannot arise from the behavior of a single species, yet all species, if they have any validity, must conform to the principles. The role of this mild zoocentricity in breaking down the sturdy picket fences that existed before Darwin's time ranks as one of the great events in the history of human thought. But the zoocentric view can be extended too far into a caricature often called the "nothing but" fallacy (humans are "nothing but" animals).

The simplistic accounts of human sociobiology now flooding popular literature embody this overextended version of zoocentrism. Sociobiology is not just any statement that biology, genetics, and evolutionary theory have something to do with human behavior. Sociobiology is a specific theory about the nature of genetic and evolutionary input into human behavior. It rests upon the view that natural selection is a virtually omnipotent architect, constructing organisms part by part as best solutions to problems of life in local environments. It fragments organisms into "traits," explains their existence as a set of best solutions, and argues that each trait is a product of natural selection operating "for" the form or behavior in question. Applied to humans, it must view *specific* behaviors (not just general potentials) as adaptations built by natural selection and rooted in genetic determinants, for natural selection is a theory of genetic change. Thus, we are presented with unproved and unprovable speculations about the adaptive and genetic basis of specific human behaviors: why some (or all) people are aggressive, xenophobic, religious, acquisitive, homosexual, and so on.

Zoocentrism is the primary fallacy of human sociobiology, for it rests on the argument that if behaviors of "lower" animals with simple nervous systems arise as genetic products of natural selection, then human behavior should have a similar basis. Humans are animals too, aren't we? Yes, but animals with a difference. And that difference arises, in part, as a result of enormous flexibility based on the complexity of an oversized brain and the potentially cultural and nongenetic basis of adaptive behaviors—aspects of human construction that debar any zoocentric extrapolation from why some insects eat their mates to murder in human families.

Ironically, the zoocentrism of human sociobiology is often an illusion hiding a precisely opposite mode of reasoning. I argued previously that "objective" systems are often unconscious masquerades that reflect our own prejudices and hopes imposed upon nature. Much of human sociobiology trades upon the idea that if distinctive human behaviors can be found, albeit in rudimentary form, among "lower" animals, then these behaviors must be "natural" in humans too, a product of biological evolution. Sociobiologists are often fooled by misleading external and superficial similarity between behaviors in humans and other animals. They attach human names to what other creatures do and speak of slavery in ants, rape in mallard ducks, and adultery in mountain bluebirds. Since these "traits" now exist among

**THE NIKON FE**
**A CAMERA TO STIR YOUR EMOTIONS**

*A favorite of professionals, the FE is the creative camera par excellence – the embodiment of Nikon sophistication.*

*Its precise meter system sets correct exposures with uncanny accuracy, automatically. Or, just turn a dial for complete manual control. Either way, the pictures are razor sharp... pure Nikon.*

*Offering combined capabilities found in no other automatic, it accepts Nikon's extraordinary lenses, accessories and a true 3.5 fps motor drive.*

*A modern 35mm classic, the Nikon FE is the finest compact automatic in its class. Priced to make it an irresistible value too! Why settle for anything less.*

©Nikon Incorporated 1980 Garden City, New York 11530

"lower" animals, they can be rederived for humans as natural, genetic, and adaptive. But they never did exist outside a human context. If mallard males seem to force physically weaker females to copulate, what possible relationship, beyond meaningless superficial appearance, can such an act have with human rape? No one can argue that the two behaviors are truly homologous—that is, based on the same genes inherited from a common ancestor. If the similarity is meaningful, it can only be analogous—that is, reflecting different evolutionary origins but performing the same biological function. Yet mallard behavior is part of the normal repertoire and seems to have evident utility in increasing the reproductive fitness of males; while human rape is a social pathology rooted in power and powerlessness, not in sex and reproduction.

Is this not mere pedantic grousing? Aren't the human terms a cute, graphic, and acceptable shorthand for what we all recognize as a more complex reality? Not when a colleague describes aggressive responses of male mountain bluebirds toward other males in the vicinity of its nest with these words: "The term 'adultery' is unblushingly employed . . . without quotation marks, as I believe it reflects a true analogy to the human concept . . . . It may also be prophesied that continued application of a similar evolutionary approach will eventually shed considerable light on various human foibles as well."

Such an old story. We hold a mirror to nature and see ourselves and our own prejudices in the glass. Historical examples abound. Aristotle described the large bee that leads the swarm as a "king," and this misidentification of the only sexual female around persisted for nearly two thousand years, at least to an Elizabethan madrigal I sang last week with the lines: "I do love thee as the spring/Or the bees their careful king" (careful, that is, in the old sense of caring, not the modern meaning of cautious). Zoocentric systems fail primarily because they never are what they claim to be. The "objective" animal behavior, under which they subsume human acts, is an imposition of human preferences from the start.

The more venerable, anthropocentric systems at least have the virtue of explicit self-recognition. They take Protagoras seriously in his claim that "man is the measure of all things," and falter only in the hubris of arguing that evolution undertook its elaborate labor of some 3½ billion years only to generate the little twig that we call *Homo sapiens*. Anthropocentric systems have been out of vogue among scientists, at least in England and America, since Darwin's time, but one version enjoyed some spectacular popularity a few years back—the system of a man I discussed in quite a different context last month, the Jesuit priest and distinguished paleontologist Pierre Teilhard de Chardin.

When Teilhard died in 1955, his evolutionary speculations, long suppressed by ecclesiastical authority, saw light, and his best seller, *The Phenomenon of Man*, became a cult book of the 1960s. Teilhard's florid and mystical writing is often more difficult to decipher than his role at Piltdown, but I believe that the general line of his argument can be simply expressed. (A convinced Teilhardian might brand me as a shallow, heartless scientist, unable to appreciate the profundity of Teilhard's vision. But difficult, convoluted writing may simply be fuzzy, not deep. Teilhard's vision is rich in scope and tradition—for it is an old argument clothed in new terminology—but the essence of his position can still be stated with everyday words.)

Teilhard believed that evolution proceeds in a definite and irreversible direction. To grasp the nature of that movement, we do not look back to the origin of life and its physical properties, but to the latest product—to *Homo sapiens* itself. For life has been moving in our direction from the start. The advance of life records an ever increasing domination of spirit over matter. This ineluctable increase in consciousness can be grasped by studying two of its material products: among lower animals, diffuse and simple nervous systems evolve into centralized organs (brains) with subsidiary parts; among higher animals, brains increase in size and complexity throughout evolution. In an autobiographical essay, Teilhard wrote:

> I never really paused for a moment to question the idea that the progressive spiritualization of matter—so clearly demonstrated to me by paleontology—could be anything other, or anything less, than an irreversible process. By its gravitational nature, the universe, I saw, was falling—falling forwards—in the direction of spirit as upon its stable form. In other words, matter was not ultramaterialized as I would at first have believed, but was instead metamorphosed in psyche.

Human evolution is the culmination of this psychic advance. In the anthropocentric vision, life only makes sense in terms of its striving toward man. We are inextricably part of nature because nature has been yearning toward us from the start. In a 1952 manuscript on human socialization, Teilhard stated:

> Human evolution is nothing else but the natural continuation, at a collective level, of the perennial and cumulative process of "psychogenetic" arrangement of matter which we call life. . . . The whole history of mankind has been nothing else (and henceforth it will never be anything else) but an explosive outburst of evergrowing cerebration. . . . Life, if fully understood, is not a freak in the universe—nor man a freak in life. On the contrary, life physically culminates in man, just as energy physically culminates in life.

Since evolution follows a directed path, the tree of life is not a randomly ramifying network, but a bundle of branches, tied by genealogy at their base, diverging during their history, yet always moving in the same basic direction. The energy of matter compels divergence; the force of increasing consciousness imposes a common upward advance. Related species should form a set of *multiple, parallel lineages*, each diverging and adapting to a local environment, but each gaining continually in its spirit/matter ratio. Teilhard wrote in 1922 that "evolution . . . resolves itself into innumerable lines which diverge at such length that they appear parallel."

With the appearance of man, evolution has reached a crux. Spirit has accumulated far enough to reach self-consciousness. Indeed, a new layer has appeared in the earth's concentric structure. Teilhard praised the great Austrian geologist Eduard Suess for introducing the term "biosphere" as an addition to the traditional concentric layers of lithosphere and atmosphere. But consciousness, Teilhard argued, has added yet another layer: "the psychically reflexive human surface . . . the noosphere."

Teilhard describes the noosphere as a physical reality, as a thin and fragile layer, now spread throughout the earth following the emergence of human ancestors from Africa and their subsequent migration to all continents. He wrote in a 1952 manuscript: "Above the old Biosphere there is spread now a 'Noosphere.' As to the material reality of this enormous event, there is nobody who will disagree." In a posthumous essay published four years later, he described the noosphere as "the marvelous sheet of humanized and socialized matter, which, despite its incredible thinness, has to be regarded positively as the most sharply individualized and the most specifically distinct of all the planetary units so far recognized."

The emergence of a noosphere, now so thin and fragile, represents the turning point of universal evolution. Teilhard wrote in 1930:

> The phenomenon of Man represents nothing less than a general transformation of the earth, by the establishment at its surface of a new layer, the thinking layer, more vibrant and more conductive, in a sense, than all metal; more mobile than all fluid; more expansive than all vapor. . . . And what gives this metamorphosis its full grandeur is that it was not produced as a secondary event or a fortuitous accident—but in the form of a turning point essentially foreordained, from the beginning, by the nature of the general evolution of our planet.

Evolution has now reached its halfway point. Heretofore, despite the progressive gain of spirit, matter has dominated and evolutionary lineages, although moving in the same general direction, have constantly diverged. But the noosphere marks the beginning of the dominion of spirit over matter. As spirit gains the upper hand, convergence shall begin. The fragile noosphere shall thicken. The direction of a billion years shall be reversed, and conscious lineages (within *Homo sapiens* at least) will begin to converge as spirit gains rapidly in its sway over matter.

The beginnings of convergence may already be discerned in the process of human socialization. In terms of vulgar mechanics, human cultural evolution may be a process different from Darwinian biological evolution, but both participate in a higher unity as sequential aspects of universal direction. Human socialization, Teilhard writes, has engendered "a vast and specific process of physico-psychical convergency . . . whose sudden appearance and acceleration in the course of the last century is perhaps the most revolutionary event registered so far in human history. . . . The human world is decidedly caught,

today and forever, in an irresistibly tightening vortex of unification."

The rush to convergence must concentrate and accelerate until all spirit, freer and freer of encumbering matter, amalgamates at a single point that Teilhard called Omega, identified with God, and, so far as I can tell, viewed as a reality, not a metaphor or symbol. He describes this apotheosis, graphically if not with perfect clarity, in *The Phenomenon of Man*:

> Convergent movement will attain such intensity and such quality that mankind, taken as a whole, will be obliged . . . to reflect upon itself at a single point . . . to abandon its organo-planetary foothold so as to pivot itself on the transcendent center of its increasing concentration. This will be the end and the fulfillment of the spirit of the earth.
>
> The end of the world: the wholesale internal introversion upon itself of the noosphere, which has simultaneously reached the uttermost limit of its complexity and centrality.
>
> The end of the world: the overthrow of equilibrium, detaching the mind, fulfilled at last, from its material matrix, so that it will henceforth rest with all its weight on God-Omega.

And so, evolution labored for billions of years, produced perhaps a hundred million species of plants, bugs, and worms along the way, all to achieve, through the agency of one species endowed with consciousness, the union of its spiritual content with God in splendid concentration at the point Omega. All previous life existed for us and for what *we* could become. Like the floating fetus that embodies the promise of futurity at the close of *2001: A Space Odyssey*, we (or rather our thickening spirit layer, soaring upward) are the heirs and the purpose of all previous life. This is the anthropocentric vision with a vengeance.

What can one say to such a scheme? Would it be too literal and mean spirited to argue that it seems to fail at its only points of testable contact with the fossil record? Few paleontologists can discern any general, much less inevitable, trend to increasing braininess in the history of life. Most animal species are insects, mites, copepods, nematodes, mollusks, and their cousins, and I, at least, can see no pervasive trend among them toward the domination of matter by spirit. And the evolutionary tree does look more to me like a complexly wandering and ramifying bush than a bundle of parallel twigs growing upward in a definite direction. Of course, I realize that Teilhard used the term evolution in a metaphysical sense to identify the laws of cosmic progress, not in our usual sense to specify the mechanics of organic change (which Teilhard recognized and studied, but called *transformisme*). Teilhard's technical works in paleontology are sound and solid, but they deal with *transformisme* and exist in a world of discourse quite separate from his anthropocentric vision of cosmic evolution.

Perhaps the problem with all these visions—zoocentric as well as anthropocentric—is our penchant for building comprehensive and all-encompassing systems in the first place. Maybe they just don't work. Maybe they must be defeated by the inherent complexity and ambiguity of our place in nature. How can we erect a picket fence—and secure one type of vision—when humans are so inextricably bound in nature. But how can we opt for complete continuity, either by working up from other animals (zoocentric) or down from humans (anthropocentric)—and thus secure the other type of vision—when humans are so special, for better or for worse. We are but a tiny twig on a tree that includes at least a million species of animals, but our one great evolutionary invention, consciousness—a natural product of evolution integrated with a bodily frame of no special merit—has transformed the surface of our planet. Gaze upon the land from an airplane window. Has any other species of animal ever left so many visible signs of its relentless presence?

We live in an essential and unresolvable tension between our unity with nature and our dangerous uniqueness. Systems that attempt to place and make sense of us by focusing exclusively either on the uniqueness or the unity are doomed to failure. But we must not stop asking and questing because the answers are complex and ambiguous. We can do no better than to follow Linnaeus's advice, embodied in his description of *Homo sapiens* within his system. He described other species by the numbers of their fingers and toes, their size and their color. For us, in place of anatomy, he simply wrote the Socratic injunction: Know thyself.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

# The $200 Bottle...

## and other examples of the money-making collectibles market.

| Item | Original Price | Price Today |
|---|---|---|
| **Advertising Calendar** It has increased more than 300 times in value! | 6¢ | $20 |
|  **Basket** A century later it has increased almost 650 times. | 30¢ | $200 |

## Examine Volume One for 10 days FREE!

TIME-LIFE BOOKS, Time & Life Building, Chicago, IL 60611

**Yes,** I would like to examine Volume One of THE ENCYCLOPEDIA OF COLLECTIBLES series. Please send it to me for 10 days' free examination along with *The Collectors Handbook* and *The Official Price Guide to Antiques and Other Collectibles*, and enter my subscription to the series. If I decide to keep Volume One, I will pay $8.95 ($9.95 in Canada) plus shipping and handling. I then will receive future volumes in THE ENCYCLOPEDIA OF COLLECTIBLES, shipped one at a time, approximately every other month. Each is $8.95 ($9.95 in Canada) plus shipping and handling and comes on a 10-day free-examination basis. There is no minimum number of books that I must buy and I may cancel my subscription at any time simply by notifying you. If I do not choose to keep Volume One, I will return it and *The Official Price Guide* within 10 days, my subscription for future volumes will be canceled, and I will be under no further obligation. *The Collectors Handbook* is mine to keep in any case. *An original collection of art for your home . . . in fine porcelain and pure 24 karat gold.*

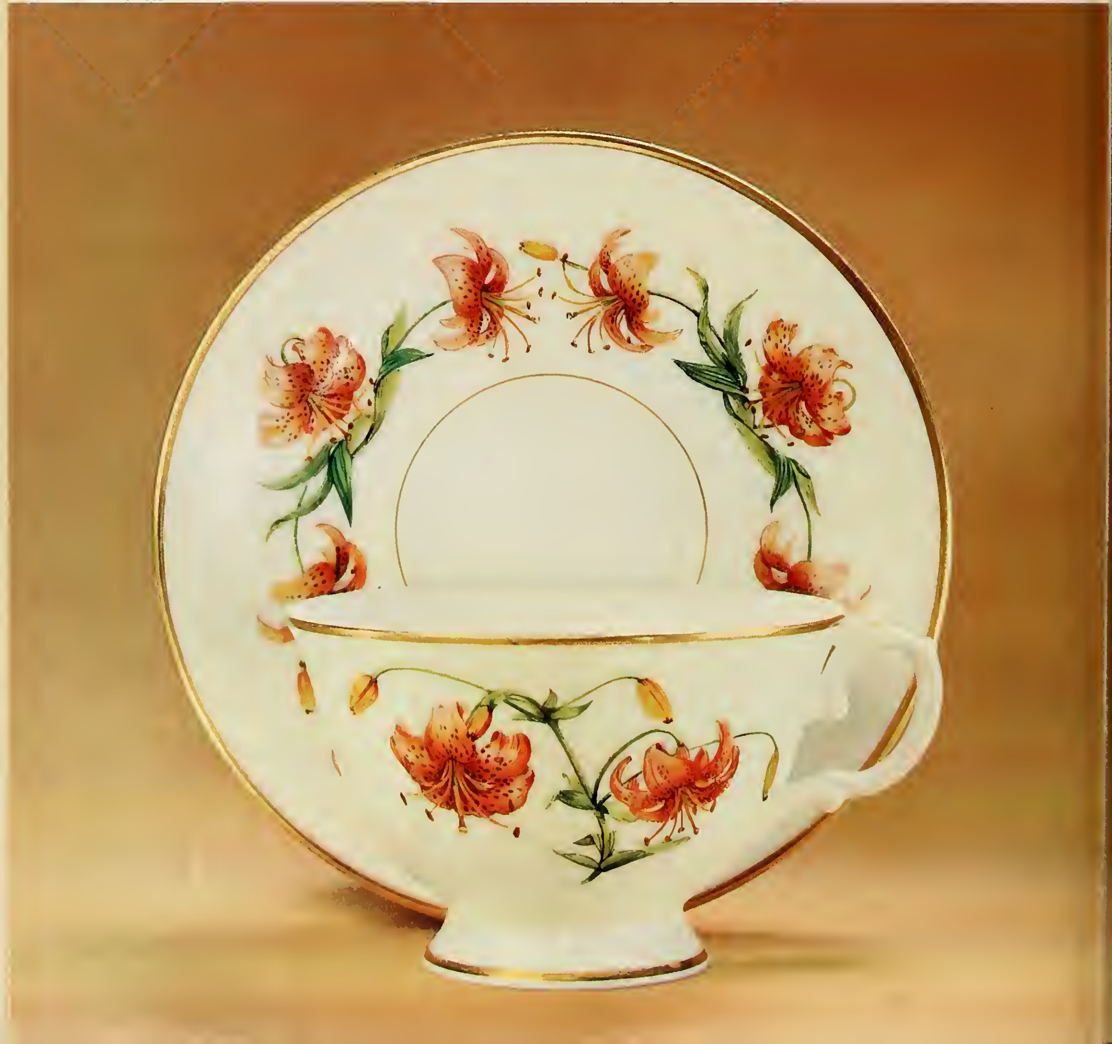
*The Royal Dutch Horticultural Society presents*

# The Flowers of Holland Cup and Saucer Collection

*Twelve elegant cups and saucers of fine porcelain, hand-decorated with 24 karat gold — portraying the best-loved flowers of The Netherlands.*

HOWN APPROXIMATELY ACTUAL SIZE



Issued in limited edition.
Advance subscription deadline:
September 30, 1980.

Holland has long been celebrated as "the land of flowers." For, in the spring, the fields become a patchwork quilt of vivid colors, dazzling with brilliant blossoms. Jewel-like begonias in radiant pink . . . cheerful daffodils of sunny gold . . . anemones in velvet red . . . tulips clad in royal purple . . . and countless others. Flowers cherished by cottage gardener and connoisseur alike. And flowers which, through the centuries, have been immortalized in many remarkable works of art.

In this tradition of outstanding floral art, The Royal Dutch Horticultural Society has authorized Franklin Porcelain of Amsterdam to create a unique collection. *The Flowers of Holland Cup and Saucer Collection.* Twelve collector's cups and saucers in fine porcelain, each portraying one of Holland's best-known and best-loved flowers. The cups and saucers have been designed exclusively for this collection by the internationally renowned artist in porcelain, Ronald Van Ruyckevelt.

## Jewels of nature faithfully re-created

*The Flowers of Holland Cup and Saucer Collection* will be crafted in fine porcelain, whose exceptional whiteness is ideally suited to bring out the dazzling beauty of each flower. And in creating this collection, Van Ruyckevelt has taken infinite care to retain all the lively freshness of the flowers themselves. His meticulously accurate works of art—at once brilliant and subtle, striking and completely natural—capture these beautiful jewels of nature, using as many as 16 separate ceramic colors.

Here is the flamboyant speckled headdress of the tiger lily; the vibrant, bursting blossoms of the cyclamen; the stately iris; the dainty star shaped florets of the hyacinth; the slender, graceful freesia. Even the smallest details are faithfully captured—the specks at the throat of the gladiolus . . . the delicate stamens of the crocus . . . the tiny checkered patterns on the petals of the fritillary. For a perfect finishing touch, each cup and saucer is *hand-decorated* with borders of 24 karat gold. And each will be provided with its own special display stand.

## Works of art to display and enjoy in your home

The result is a sheer joy for the collector. Twelve exquisite works of art in fine porcelain. To display with pleasure in a china cabinet, a breakfront—or as an elegant addition to your dining table. For as well as being a pleasure just to look at, these graceful cups and saucers will bring distinction to that special luncheon, tea or dinner. This is a collection created for a lifetime of enjoyment . . . and one which is likely to be passed along as an heirloom to future generations.

*The Flowers of Holland Cup and Saucer Collection* is an official issue of The Royal Dutch Horticultural Society. The Society has assigned responsibility for its crafting and distribution to Franklin Porcelain of Amsterdam. In the United States, it is available, by special arrangement with the Society, exclusively from Franklin Porcelain.

The collection will be produced only once and, as is traditional for fine porcelain issues, it will be withdrawn after a limited period of time.

Each cup and saucer will be crafted, of fine Japanese porcelain, solely for subscribers. Individual cups and saucers will not be sold separately. And there is a further limit of one collection per subscriber.

Thus, the total edition will be forever restricted to the exact number of subscriptions entered during the limited offering period. For, after the final closing date of December 31, 1981—these collector's cups and saucers will never be available again, anywhere in the world.

The collection will be accompanied by a Certificate of Authenticity signed by the President of the Society and attesting to the limits of edition. And each subscriber will also receive a specially written commentary, describing each of the flowers portrayed in the collection.

## Your application must be postmarked by the advance subscription deadline of September 30, 1980.

*The Flowers of Holland Cup and Saucer Collection* will be issued on a convenient subscription plan, at the rate of one cup and saucer every other month beginning in November. The original issue price of just $25 per cup and saucer—payable in two equal monthly installments of $12.50 each—*is guaranteed for the entire collection.*

But please note that, in order for your subscription to be accepted, it is important that the attached application be postmarked by the advance subscription deadline of September 30, 1980.

ADVANCE SUBSCRIPTION APPLICATION

## THE FLOWERS OF HOLLAND CUP AND SAUCER COLLECTION

Must be postmarked by September 30, 1980.
Limit: One collection per subscriber.

Franklin Porcelain
Franklin Center, Pennsylvania 19091

I wish to enter my subscription for *The Flowers of Holland Cup and Saucer Collection*, consisting of twelve fine porcelain cups and saucers, hand-decorated in 24 karat gold, at the price of $25.* each. With each cup and saucer, I will also receive a specially designed display stand.

I need send no money now. The twelve cups and saucers are to be sent to me at the rate of one cup and saucer every *other* month. I will be billed for each cup and saucer in two equal monthly installments of $12.50*, with the first installment due in advance of shipment.

*Plus my state sales tax and $1.50 for shipping and handling

Assembly of Animals

Since its publication, the **New Larousse Encyclopedia of Animal Life** has sold over 250,000 copies because of its thoroughly authoritative text and superb range of photographs of the animal world—from minute single-celled creatures to the largest mammals.

This new 9"x12", 640-page edition, edited by Maurice Burton, D.Sc., continues this high standard by combining some of the best animal color photography with an up-dated and revised text. The depth of detail is reflected in the selection of 800 color photos of creatures from every continent, every major animal group, and every zoological class. There is new data on classification, development, breeding, migration, plus glossary and index.

A truly indispensable guide for the naturalist and enthusiast. $50.00

# The Food Connection

*New crops and increased production allow populations to soar*

**by Peter Farb and George Armelagos**

The modern cultural adaptation that emerged first in Britain, then in Western Europe and North America, is now spreading rapidly around the globe—and even penetrating into the lands of remote pastoralists, horticulturists, and hunter-gatherers. Often regarded as synonymous with the Industrial Revolution—which began almost exactly two hundred years ago with James Watt's improved version of the steam engine—modernization entails much more than the replacement of human muscle by energy from machines. It involves developments in the structure of the family, the division of labor, the growth of population, and the environment, as well as diet.

The Industrial Revolution could not have taken place without the agricultural revolution that preceded it and that was based on an increase in production due both to new crops from the Americas and to new methods of farming. Yields of food were increased substantially by such simple techniques as the rotation of crops—a sequence from year to year, for example, of barley, clover, wheat, and turnips, instead of leaving the field fallow when its fertility had been depleted. The selective breeding of cattle also greatly increased the yields of meat and milk. In such ways, what had been an inefficient system of agriculture was eventually replaced by large-scale mechanized farming that took on the character of modern industry. Oliver Goldsmith in his poem *The Deserted Village*—published in 1770, five years before Watt's improved steam engine first came into use—described how the mechanization of agriculture had already forced many farmers to abandon their small holdings and migrate to the cities. This considerable portion of the British population provided the labor for an industrialization that would otherwise have been impossible.

One phenomenon of modernization has been an increasingly rapid rise in population. In 1750 the total population of the world was probably about 750 million, by 1830 it had increased to a billion, by 1930 it was two billion, and by 1975 four billion. In other words, the human species needed millions of years to reach a population of a billion, but thereafter the second billion was added in only a hundred years, the third in thirty years, and the fourth in a mere fifteen years. This growth was long attributed to a drop in the death rate that stemmed from advances in medicine, but some demographers now question whether medicine had much of an effect. Tuberculosis, for example, was the largest single cause of death in Britain in the last century, yet in the fifty years previous to 1882—when the tubercle baccillus was first identified by Robert Koch—deaths caused by it had already declined by about half. Pneumonia, influenza, infectious bronchitis, and other diseases also be-

Material adapted from *Consuming Passions: The Anthropology of Eating*, published by Houghton Mifflin © 1980 by the Estate of Peter Farb.

gan significant declines early in the nineteenth century, years before immunization and potent new drugs could have had any effect.

If not medical advances, then what can explain the change in the response to infection by people living in modern societies? The answer seems to be the profound effect of improved nutrition on the body's response to microorganisms. The decline in the death rate that occurred in Europe and in North America during the last century is being witnessed today in developing nations, and has the same probable cause. Well-nourished people have a much lower rate of infection and, even if infected, are much more likely to recover as compared to poorly nourished people. Before the widespread use of the measles vaccine, practically every child in every country caught measles, but three hundred times more deaths occurred in the poorer countries than in the richer ones. The reason was not that the virus was somehow more potent in poor countries or that these lacked medical services, but that in poorly nourished countries the virus attacked children who, because of chronic malnutrition, were less able to resist it.

Along with an improved agriculture came the introduction into Europe of new crops from the Americas, notably white potatoes into northern Europe and maize into southern Europe. In both Spain and Italy, where the cultivation of maize was widespread, populations soared—nearly doubling in Spain and increasing from eleven to

eighteen million in Italy between the beginning and the end of the eighteenth century. The potato was not accepted so readily in Europe, even though it had been cultivated in the Andean highlands of Peru for about 2,500 years. It was at first regarded with suspicion, in part because it was grown from a tuber rather than from seeds, as were all other edible plants in Europe up to that time. But by the beginning of the eighteenth century, the potato had become a common food for peasants, who found in it the perfect crop for small parcels of arable land. Just one acre planted to potatoes could feed a family of five or six, plus a cow or pig, for most of a year. The plant could grow in a wide variety of soils, and it required no tools other than a spade and a hoe. It matured within three or four months, as compared to the well over half a year required for grain crops, and it had the advantage of a high nutritional value.

The most dramatic effect of the potato's introduction into Europe was seen in Ireland. By the middle of the eighteenth century, most of the Irish population was subsisting almost exclusively on potatoes, and Ireland's perennially recurring famines appeared at last to be ended. Potatoes do not have aphrodisiac powers, as was once believed, but they did contribute to the sudden increase in the Irish population, making large families possible because they provided a maximum of sustenance with a minimum of labor. The population of Ireland grew from just above three million in 1754 to more than eight million in 1845. Then a blight struck, bringing about the Great Potato Famine that was to last four years.

An increase in population as a result of new foods rather than of industrialization and medical advances also took place in China. The sweet potato, long grown by South American Indians, was early imported as a crop into China and was established by 1594, when it provided sustenance at a time when the native grains were succumbing to drought. An eighteenth-century agricultural commentary extolled sweet potatoes as a versatile crop that could be boiled, ground, or fermented; could be fed to animals, as well as to humans; and could grow in sandy, mountainous, and salty soils where grains did not survive. By that century, other New World crops were being widely grown: maize was allowing people from the crowded Yangtze region to migrate inland and farm drier lands; the white potato made it possible to bring into production lands that were too impoverished even for growing maize; and peanuts could be grown in the previously useless soils along rivers and streams. The new crops allowed a Chinese population that had reached the limits of its previous resources to begin a new spurt in growth. The numbers expanded from about 150 million people in the early 1700s to about 450 million only a century and a half later. The worldwide growth in population over the past several centuries is similar to what occurred in China, and can be assumed to have occurred for similar reasons. As soon as food resources could be moved from continent to continent because of the invention of long-distance transportation, a surge in population took place, one that had little to do with industrialization, shorter work hours, or advances in the practice of medicine.

People in modern societies usually assume that their own kind of mechanized agriculture is the most efficient known. But if the question is asked whether mechanized producers are really extracting from the soil a greater number of calories of food in proportion to the calories of energy they expend, the answer is no. In fact, they are very inefficient in this regard when compared with other adaptations—as is shown by a simple equation developed by anthropologist Marvin Harris that makes it possible to analyze the efficiency of any system for providing food energy:

$$\frac{E}{m \times t \times r} = e$$

That is, a society's annual production of food energy, *E* (as expressed in thousands of calories, or kilocalories), divided by the number of food producers (*m*), times the hours each works at food production during the year (*t*), times the calories expended per producer each hour in doing the work (*r*) equals *e*, that society's techno-environmental efficiency (in other words, the calories produced for each calorie of energy expended). Obviously, *e* must be greater than one because no society can survive for very long unless it produces more energy than it expends; actually, the value of *e* must be substantially higher than one to provide for such nonproducing activities as toolmaking, ceremonials, and recreation, among other things, and also to support the young, the elderly, the sick, and other nonproducers in the society. The larger *e* becomes, therefore, the greater is the society's techno-environmental efficiency in producing food energy above the amount it expends.

In a hunting-gathering society, such as the San, or Bushmen, of the Kalahari Desert, the equation is applied by Marvin Harris (using data collected by Richard Lee) as follows: A camp of twenty adults ($m$), each working 805 hours a year ($t$) and expending 150 calories per hour ($r$), to produce 23,000,000 kilocalories annually ($E$), has an efficiency of 9.5 ($e$)—which means that the San are producing between nine and ten calories for each calorie of energy expended.

This low efficiency does not allow much of a margin of safety and is insufficient to provide food for full-time specialists such as woodcarvers or priests. But the San cannot increase their efficiency because the average expenditure per producer of 150 calories an hour cannot be raised substantially; the human body simply cannot withstand long periods of being overheated or out of breath (which is why the average value for $r$ of 150 remains the same in all of the adaptations to be discussed here). For each adult in the camp to work more than 805 hours a year (an average of a mere two hours or so a day) would not solve the problem because the San can neither transport nor store a surplus, and any increased effort would quickly deplete the food resources around the camp. They might try to enlarge the population of their camp to increase the number of producers, but the food supply in the Kalahari Desert is insufficient to support dense populations that lack the knowledge and tools to build irrigation dams. So long as the San follow their traditional ways, they obviously can do almost nothing to increase their techno-environmental efficiency.

Nor would it be possible for the San to switch to horticulture, given both the harsh environment and their limited technology for overcoming it. Even if they could, Marvin Harris has shown, using energy data from a horticultural village in Gambia, West Africa, how little would be gained. Instead of the 20 food producers in the San camp, this Gambian village had 334, as well as a better climate for plant growth and a more complex technology. Yet the application of the equation shows an efficiency only slightly above that of the San. For an annual production of 460,000,000 kilocalories, 334 persons, each working 820 hours annually and expending 150 calories an hour, produce a little over 11 calories for each calorie of expended energy.

The main advantage of horticulture over hunting-gathering is not its much greater efficiency but rather that people can live together in larger and more permanent settlements. The denser population of a sedentary village allows for protection against enemies and gives greater opportunity for cultural interaction.

Detailed energy data do not exist for pastoral peoples, but their efficiency is believed to be no greater than for hunter-gatherers and horticulturists. It may indeed be less, since to allow domesticated animals to eat plant foods and then to eat the animal or its milk and blood takes the process of production through an extra step, with a loss of calories along the way. This assumption seems supported by the few studies that have been made. For one tribe of southern Tunisia that herds sheep and goats and also practices a little horticulture, anthropologist William Bedoian has calculated a techno-environmental efficiency of about six; for some Indians in the Andes of South America who are almost exclusively pastoralists, R. Brooke Thomas has determined the figure to be a little more than two.

Figures on efficiency under other adaptations do not increase by much until the complex level of irrigation agriculture is reached. This adaptation can feed more people on less land than any other, including mechanized agriculture. Over the millenniums, it has developed most notably in eastern Asia because of particular conditions prevailing there: many people to provide the labor for building and maintaining irrigation works, abundant water, and a shortage of arable land. As the irrigation system develops and production is intensified, more and more people are fed from the same amount of land—although at the price of increasing the amount of labor per unit of land, which means that the land must be worked ever more intensively by more people. Given this cycle, no one can become richer by working harder because the payments allocated to labor must be divided among a larger and larger force. And

VIDEOCASSETTE MOVIES
FROM THE VIDEO CLUB OF AMERICA

You can choose from over 300 of the most-wanted videocassette movies and programs on the market today when you join THE VIDEO CLUB OF AMERICA. The quality is tops; you can purchase a full-length film for as little as $44.95; and it costs only $10 to join the Club for a lifetime. THE VIDEO CLUB OF AMERICA is a convenient source for all your video needs—including blank videocassettes and accessories. You'll receive only those items you specifically order AND YOU ARE NEVER OBLIGATED TO BUY. So why not send your membership order today? Join immediately and you'll receive a special "2-for-1 coupon" entitling you to a FREE videocassette with the first one you buy of equal or greater value! As a member you'll also receive our 38-page, full-color 1980 Program Catalog (VHS or Beta-II formats available). You'll get our quarterly newsletter notifying you of special Club discounts—and, if you're about to purchase your first VCR—a glossary of video terms and equipment display sheet to help you shop more knowledgeably. since such systems can develop only in the presence of an autocratic government, any economic growth that occurs is inevitably siphoned off by the bureaucratic elite that exists outside of the energy system.

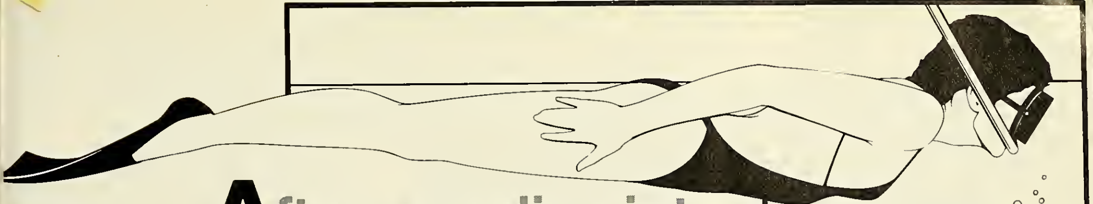
A detailed study of labor inputs and food yields for an irrigation village in Yunnan Province, China, before the fall of the Nationalist government shows a greatly increased techno-environmental efficiency over hunting-gathering, horticulture, and pastoralism. Four hundred eighteen persons, each working 1,129 hours annually, produced 3,788,000,000 kilocalories, resulting in between 53 and 54 calories produced for each calorie of energy expended. A higher efficiency, it should be noted, does not produce an increase in leisure, as is often supposed. Rather, each producer must work harder—in fact, some 35 percent more labor was performed by each of these Chinese than by each of the San.

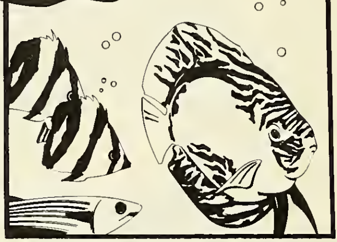
Of the nearly four billion kilocalories produced annually by this Chinese village, the villagers were estimated to need no more than a sixth of that amount. What happened, then, to the more than three billion kilocalories they produced each year over what they consumed? The surplus was used to feed the scores of millions in Chinese towns and cities who did not participate directly in food production, was sent to market and exchanged for manufactured goods, or was taken away in the form of taxes levied by the local, provincial, and national governments and in the form of rent payments to large landowners.

Modern societies are too complex to be analyzed by the equation employed here, but a few generalizations can be made. Once again, it is a mistake to suppose that modern societies allow people to work less hard for their daily bread. Out of the 1,129 hours worked by one Chinese irrigation farmer in a year, only 122 were needed to grow enough food to sustain that farmer. A blue-collar worker in the United States, on the other hand, spends 180 hours earning enough money to purchase a year's supply of food. Notwithstanding Western notions of the Chinese peasants' incessant labor, it is plain that they actually need to work less by a third than North Americans or Europeans to keep themselves supplied with food. Moreover, although a mechanized farmer in the American Midwest need put in an annual total of only nine hours of work for each acre to achieve an astounding 6,000 calories for each calorie of effort, that figure ignores the enormous amounts of human labor that go into manufacturing and transporting the trucks, tractors, combines, fuel, fertilizer, pesticides, fence wire, and everything else used by the farmer, not to mention transporting the food itself. For every person who actually works on a Midwestern farm, the labor of at least two others off the farm is needed to supply equipment and services directly to the farmer—aside from the very many more whose labors contribute indirectly to the final product. Altogether, a total of 2,790 calories of energy must be expended to produce and deliver to a consumer in the United States just one can of corn providing a total of 270 calories. The production of meat entails an even greater deficit: an expenditure of 22,000 calories is needed to produce the somewhat less than four ounces of beefsteak that also provides 270 calories.

In short, present-day agriculture is much less efficient than traditional irrigation methods that have been used by Asians, among others, in this century and by Mayas, Mesopotamians, Egyptians, and Chinese in antiquity. The primary advantage of mechanized agriculture is that it requires the participation of fewer farmers, but for that, the price paid in machines, fossil fuels, and other expenditures of energy is enormous. A severe price is also paid in human labor. Once the expensive machines have been manufactured and deployed on the farms, they are economically efficient only if operated throughout the daylight hours, and indeed farmers in the United States often labor for sixteen hours a day. The boast of industrialized societies that they have decreased the workload is valid only in comparison with the exploitation of labor that existed in the early decades of the Industrial Revolution. If the prevailing forty-hour work week of North America and Europe were proposed to the San, whoever did so would be considered to be exploitive, inhuman, or plain mad.

*Peter Farb, recently deceased, was an anthropologist and the author of* Man's Rise to Civilization *and* Humankind. *George Armelagos is a professor of anthropology at the University of Massachusetts.*





# After you dive into Cartagena's ancient walled city where the pirates hid, peer into a magical deep sea world. Play on a native island. It all happens in Colombia's Caribbean. From $379.

Per person price based on double occupancy & includes roundtrip Avianca GIT jetfare from New York ($319 from Miami), Class A hotel, baggage handling, transfers, U.S. departure tax, city tour. Airfare subject to change.

# Paradise is a sun-soaked, moonlit escape called Santa Marta. White sands, blue water, balmy nights. Romantic Colombia. From $553.

Per person price based on double occupancy & includes roundtrip Avianca GIT jetfare from New York ($439 from Miami), jetfare to Santa Marta; three days in Cartagena, Class A hotel; four days in Santa Marta, top hotel, all transfers, U.S. departure tax, city tours. Airfare subject to change. American Express calls this tour "Spanish Legend." Prices slightly higher after December 31, 1980.

First airline of the Americas,
second oldest in the world.

# Acrobatic Pygmy Chimpanzees

*The behavior of this smallest of the great apes may help in interpreting the fossil record of human evolution*

**by Randall Susman**

**photographs by Noel Badrian**

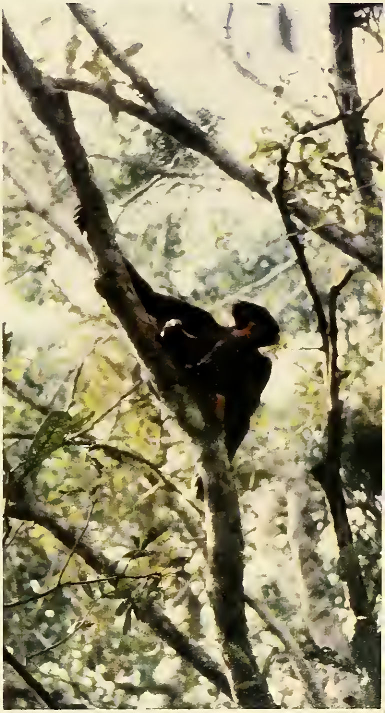
Lofinda, one of our guides, whispered softly and motioned toward the high canopy of the trees. I tried to find the pygmy chimpanzee but saw only a mosaic of green leaves, broken by beams of bright sunlight. With his finger frozen on the point where the animal was, Lofinda turned to me and again whispered, "Edja." Frustrated, I moved close to him, put my chin on his shoulder, sighted along his extended arm to the tip of his index finger, and finally spotted a dark silhouette perched on the end of a bough some eighty feet from the ground. At that moment the animal detected us, and as I focused my binoculars, he quickly moved closer to the center of the tree. There he grabbed another branch with one hand and swung along it to the trunk where he hesitated and looked down toward us. He was a magnificent animal, with a lustrous black coat. His pink lips contrasted with the coal black skin of his face, his nose was strikingly gorillalike, and his brow was an unbroken, heavy shelf across his forehead. The black hair on his face formed sideburns; the hair on his head was parted at the midline. He seemed to stare momentarily into my binoculars; then he scrambled to the trunk of the tree, paused, and slid down, fireman style, for thirty or forty feet. With a crash he dropped the last six or so feet to the ground and was off into the forest.

Weary, but exhilarated by my first contact with a wild pygmy chimpanzee, I sat down to rest. It had been three hours since our party had left camp to search for pygmy chimpanzees. We had arrived at our study site earlier that morning following a fourteen-day journey from Kinshasa, the capital of Zaire. After seven years of studying apes in the laboratory, I was thrilled to see these animals under natural conditions. Four years earlier, my colleague Noel Badrian and his wife, Alison, had conducted a six-month study of the pygmy chimpanzee *(Pan paniscus)* in this area. The first primatologists to observe pygmy chimpanzees in the wild, they had gathered some ninety hours of observations on social behavior, feeding, and other aspects of pygmy chimpanzee ecology. Unfortunately, their study was cut short for lack of funds. I returned to the Lomako Forest with Noel to gather data on locomotor behavior and add to the Badrians' earlier work. Noel, Alison, and I hoped that our studies would prove that careful observations of pygmy chimpanzee behavior could be carried out in the field and that our efforts would develop into a long-term project on the behavior and ecology of pygmy chimpanzees.

These animals, which we had come so far to observe, first captured the attention of anthropologists some fifty years ago, when the study of great ape behavior began to come into its

*Perched high in the canopy, a robust adult male pygmy chimpanzee is unaware that he is being observed. The name "pygmy" is clearly a misnomer since large males often weigh more than 100 pounds.*

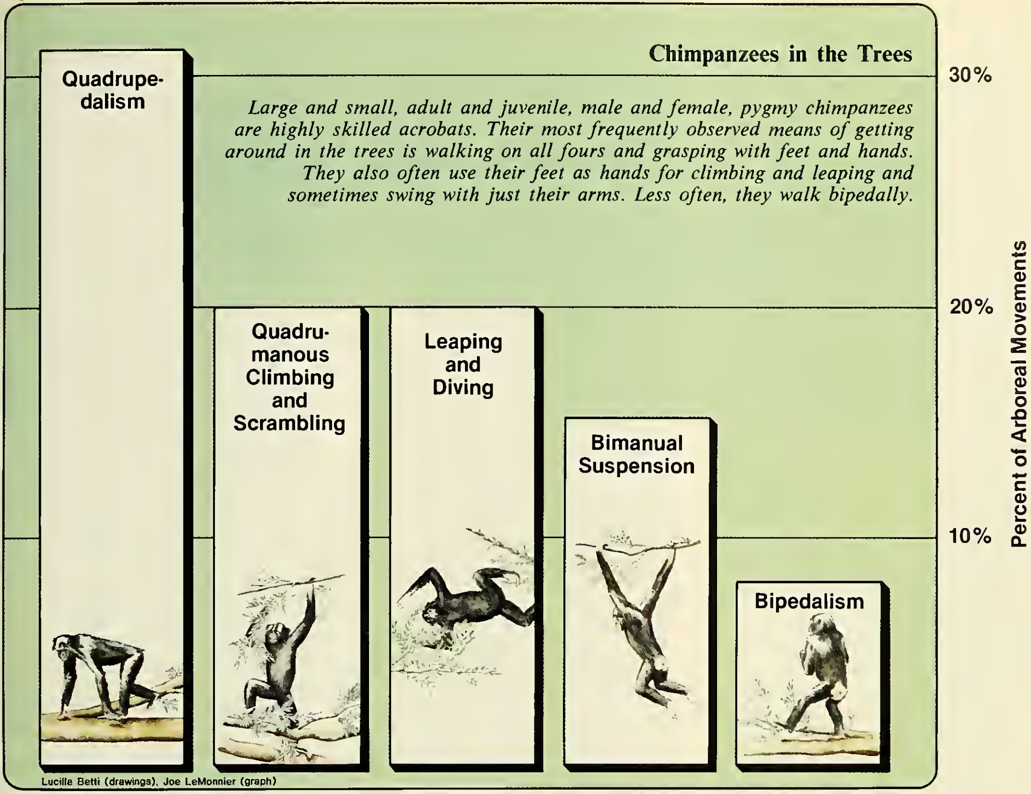
*From its vantage point high in a tree, a young male pygmy chimpanzee looks down at the photographer. Such males will often approach an observer, attracting attention to themselves while other chimpanzees in the group slip away.*



own. Although captive pygmy chimpanzees were observed in the mid-1920s by Robert Yerkes and others, the animal was not recognized as a distinct species until Ernst Schwarz's work in 1929. Harold Coolidge published the first detailed paper on the biology of the pygmy chimpanzee in 1933. Using museum records of localities from which specimens were collected, Coolidge mapped out the range of the pygmy chimpanzee, as he called the animal. He noted that the pygmy chimpanzee was found on the left bank of the Zaire (formerly Congo) River, while the common chimpanzee occurred on the right bank to the north. Coolidge further reported the eastern extent of the range as the Lomami River, and roughly defined the southern boundary by a line connecting Lukolela in the west and Mondombe in the east. Although a number of different distribution maps for the pygmy chimpanzee have been published since Coolidge's, information collected during the past few years shows that his map provides the most accurate assessment of the species' range.

From the start, anthropologists and primatologists were intrigued by descriptions of a dwarf, or pygmy, chimpanzee. (No one now believes that the creature is a true pygmy version of the common chimpanzee, but the name is still in popular usage.) The Dutch anatomist Louis Bolk had published his "fetalization theory" of human evolution in 1925, and Raymond Dart had almost simultaneously reported on the finding of an ancient, small, apelike hominid from South Africa—*Australopithecus africanus.* Bolk proposed that the human body form was the result of hormonally regulated "retardation" of growth processes. At maturity, humans have not moved as far from their juvenile or fetal stages as have adult apes. In fact, juvenile humans, monkeys, and apes are morphologically quite similar. Monkeys and apes, however, display accelerated adolescent growth

*Because of their small size, black mangabey monkeys can leap farther than can pygmy chimpanzees. The quieter chimpanzees are often found by locating the raucous monkeys with whom they frequently feed.*



**Chimpanzees in the Trees**

*Large and small, adult and juvenile, male and female, pygmy chimpanzees are highly skilled acrobats. Their most frequently observed means of getting around in the trees is walking on all fours and grasping with feet and hands. They also often use their feet as hands for climbing and leaping and sometimes swing with just their arms. Less often, they walk bipedally.*

Lucille Betti (drawings), Joe LeMonnier (graph)

that, among other things, results in adults that are morphologically more distinct from their younger counterparts than is the case with humans.

Schwarz observed that adult pygmy chimpanzees also appeared to retain "youthful characters" to a great extent, while maintaining a close similarity to common chimpanzees. To add to this, Dart's description of a fossil "humanoid" skull that revealed similarities with chimpanzees and gorillas sparked a longstanding controversy that would only be resolved when much more information on the morphology of extant apes and humans (and fossil evidence) became available.

Schwarz suggested that the pygmy chimpanzee might be an important element in the debate over whether *Australopithecus* represented a "dwarfed gorilla." Schwarz, Coolidge, and other workers placed the pygmy chimpanzee squarely in the context provided by Bolk and Dart. Anthropologists were immediately excited by all the implications relating to the very existence of a pygmy chimpanzee and many new thoughts and hypotheses quickly appeared. Few anatomical studies were actually conducted on the morphology of the animal, however, and no fieldwork was undertaken for the next thirty years. The remote, restricted range of the pygmy chimpanzee in the rain forest of Zaire no doubt accounted for the latter fact.

In recent years, discoveries of fossil apes and ancient humans have rekindled interest in the evolutionary biology of the pygmy chimpanzee. First, similarities in overall size and dental and facial proportions of *Ramapithecus* (possibly the earliest bona fide member of the hominid line) and the pygmy chimpanzee engaged the attention of primate paleontologists, who took a strong interest in the morphology and behavior of the pygmy chimpanzee. Second, new finds of two- to three-million-year-old hominids in eastern Africa, as well as those found earlier in South Africa, revealed size differentials in early humans that recalled the differences between the pygmy chimpanzee and the common chimpanzee. Most important, however, was the lingering notion that the pygmy chimpanzee, smallest of the great apes, was less specialized adaptively than chimpanzees, gorillas, or orangutans, and that for this reason it might provide the best living analogy with the behavioral patterns of our earliest apelike human ancestor.

As Coolidge had stated some thirty years earlier, less specialized meant, to most people, that an animal more closely resembled an ancestral state than did a more specialized form. Coolidge further noted that "the paniscus, a true paedomorphic species which shows definitely juvenile characteristics in an adult state, is the most important of the chimpanzees in a study of the phylogeny and relationships of this higher order of anthropoid apes. It may approach more closely to the common ancestry of chimpanzees and man than does any living chimpanzee. . . ." Specifically, the questions that were formulated in the late 1960s were (1) What is the place of the pygmy chimpanzee in the phylogeny of the African apes and humans? and (2) How can investigations incorporating behavioral and anatomical data on *Pan paniscus* aid in reconstructing the behavior of early human ancestors?

In the early 1970s extensive studies of the teeth and skulls of pygmy chimpanzees and preliminary investigations of their skeletons were carried out. Attempts to collect data on the behavior of free-ranging pygmy chimpanzees were also made and more formal studies of captive behavior were begun. From the information that was gathered, two poles of opinion emerged on the question of the phylogenetic affinities of the pygmy chimpanzee and its place in the family tree of African apes and humans.

Some scientists suggest that the pygmy chimpanzee closely represents the prototype from which humans and the African great apes have evolved. They suggest that the pygmy chimpanzee's smaller size and relatively small cranial, facial, and dental dimensions make it a better model of the prehominid ancestor than either the common chimpanzee or the gorilla. To underscore such similarities to humans these scientists further suggest—largely from observations of captive animals—that pygmy chimpanzees walk bipedally more often than common chimpanzees do and engage in more complex and variable sexual and copulatory interactions than other chimpanzees. Proponents of this school also emphasize the size similarities of early hominids and pygmy chimpanzees and the "generalized" hominoid morphology of the latter.

Other scientists, however, have pointed out that the similarities of the pygmy chimpanzee and early hominids such as *Australopithecus* or *Ramapithecus* are revealed only in a certain few morphological traits, many of which can be attributed to the overall effect of small size. In other words, these similarities in size may mask many important underlying adaptive differences. These workers feel that pygmy and common chimpanzees are equally good working models for the common ancestor of humans and African apes, and that acceptance of the pygmy chimpanzee as *the* prototype is not warranted by our limited knowledge of the species. Nevertheless, both schools agree that the pygmy chimpanzee is a highly significant, still untapped reservoir of information for interpreting the fossil record of human evolution.

The desire to make functional or behavioral inferences about the fossil record sparked my own interest in *Pan paniscus.* When similarities and differences are found between living forms, anatomists attempt to link these to similarities and differences in their behavior. In this way an explanation—or the "why"—of morphology is developed. Such observations can be applied to fossils (if the fossils are similar enough to the corresponding bones of living animals), and we can then postulate or reconstruct the behavior of extinct species. On a practical level this is difficult. Often the best we can do is suggest how a particular part of the body may have functioned—for example, the knee or the hip. But such analysis and inference often prove significant because an individual bone may be the key to understanding whether an animal habitually walked upright or on all fours; whether it climbed trees or lived primarily on the ground.

Earlier studies of pygmy chimpanzee morphology, including one of my own, have revealed subtle but distinct differences between pygmy and common chimpanzees, many of which are independent of simple size differences. These include the length of the shoulder blade, the shape of the finger bones, and the long lengths of the upper and lower limbs in the pygmy chimpanzee relative to its body weight. Statistical analyses suggest that there are significant differences among pygmy and common chimpanzees and other apes that are revealed in the hand and shoulder. These differences seem to correspond to the relative amounts of suspensory activities (hanging, climbing, and arm swinging) that occur in each species.

The data on pygmy chimpanzees were interesting and suggested, among other things, that pygmy chimpanzees are more arboreal than common chimpanzees. But we were at a loss to confirm this interpretation of our anatomical observations. Noel and I designed a brief field study to try to determine how pygmy chimpanzees moved about in their native habitat so that we could verify or deny the hypotheses developed in the labora-

*These pygmy chimpanzees, a male (right) and a female, groomed each other for an hour, alternating as groomer and groomed every few minutes. Chimpanzees often engage in this activity after feeding.*

tory about pygmy chimpanzee locomotion. We intended to eventually combine the behavioral and morphological observations and hoped the combination would help us infer the locomotor characteristics of selected fossil apes and humans, and especially, shed light on the critical question of how hominid bipedalism originally evolved.

The initial observations that Lofinda and I made were only the first of many sightings that our party made during the next four weeks. We logged nearly twelve hours of detailed observations on locomotion and feeding alone—more than anyone had previously collected. Most of the time we encountered small groups of five to eight animals feeding high in the crowns of fruit trees. Groups consisted of a large male (weighing 100 pounds or more), one or two smaller males, and two or three females—one or two of which might be carrying an infant. When we approached, the group members frequently spotted or heard us. Sometimes they continued to feed; at other times they hurriedly descended the trees and fled on the ground. In both situations a male would interpose himself between us and the group, attracting our attention with a noisy, bough-drumming, bipedal display (standing on his hind limbs, waving his arms, and vocalizing) or just moving toward us to build a nest or feed. Often, while the prominent male had our attention, the rest of the group would quietly move off. This behavior of the males recalled the sentry and display behavior of patas monkey males.

Patas monkeys live on African savannas and are notable for their behavior when threatened with danger. The males make noise and motions to attract attention while the females and the young slip off quietly. The males then run off at high speed in another direction. Neither gorillas nor common chimpanzees show such organized deception.

From footprints, plant remains, and direct observations made by Lofinda and his son Ikwa, we learned that pygmy chimpanzees spend a large part of the day on the ground. Much of their diet consists of fruit, but pygmy chimpanzees regularly eat a number of canes and herbs that are found on the forest floor. In addition, Noel and Alison had earlier observed and reported insect and small mammal remains in pygmy chimpanzee feces.

Pygmy chimpanzees are basically quadrupedal knuckle walkers when on the ground, but they engage in other mixes of walking as well. Ikwa observed a large male pygmy chimpanzee walking bipedally on the ground. When he spotted the guide, the startled animal dropped the canes he was carrying, stomped, defecated, and then turned and fled on all fours.

In the trees, pygmy chimpanzees are highly skilled acrobats, and adults are reported to be more agile and daring than adult common chimpanzees. Large and small animals of both sexes, as well as pygmy chimpanzee mothers with infants, arm swing, leap, and dive in the high canopy. Juveniles engage in acrobatic play and are also adept arboreal bipeds. We observed several instances of bipedal walking along large boughs at heights of 100 feet and more, usually when animals were carrying objects or when they engaged us with behavioral displays. The relative frequency of bipedal locomotion—it occurred in 10 percent of our observations—was comparable to that reported for gibbons by C.R. Carpenter and later workers. In one instance, Noel observed an adult male at the end of a long bough. He displayed at Noel and Ikwa, then apparently not quite finished feeding, he walked bipedally for a distance of fifteen feet or so carrying bunches of fruits in each hand.

We were able to render our findings in a quantitative way so that they could eventually be compared with similar observations on common chimpanzees and other apes. We kept a record of the number of times we observed pygmy chimpanzees in motion in the trees (arboreal locomotor bouts) and of what kinds of behavior were observed in each instance. The most frequent behavior was walking along a bough on all fours, grasping with feet and hands. This behavior occurred in more than 20 percent of the observations (a total of 41 times). Other common behaviors were scrambling along any part of the tree, using all fours (seen in about 20 percent of the observations), and leaping or diving from a bough (also seen in about 20 percent of the observations). Swinging from a bough with both arms occurred in more than 15 percent of the observations. Other behaviors were less common.

Comparisons of pygmy and common chimpanzees, even on the basis of the limited data we have at present, are provocative. Descriptions of chimpanzee locomotion by a number of researchers, including Jane Goodall, Vernon and Frances Reynolds, and Adrian Kortlandt, indicate that adult chimpanzees (which are heavier than pygmy chimpanzees by 10 to 15 percent) are cautious climbers and arm swingers in the trees. Although young common chimpanzees actively chase and play in the trees, adults engage in dynamic displays mainly when they are excited. Like pygmy chimpanzees, common chimpanzees travel from one feeding spot to another on the ground, but when in the trees, and this is a critical qualifier, pygmy chimpanzees appear to be far more acrobatic.

Our conclusion that pygmy chimpanzees are better than common chimpanzees at leaping, diving, arm swinging, and walking upright in trees rests on our quantitative assessment of the frequency and context of the various modes of pygmy chimpanzee locomotion. And it confirms our initial studies of pygmy chimpanzee and common chimpanzee anatomy, in particular the structure of the shoulder blade, arm, and hand, which suggest that the pygmy chimpanzee is more arboreal than its relative. But these are not definitive conclusions, and our studies are continuing. We need more anatomical and field studies of both animals to nail down the differences we believe we see.

If our findings are confirmed, we will have a series of living apes, closely related to, but differing in locomotor behavior from, the human lineage, that can be used to explain the morphology of fossil apes and humans. As to how good a model the pygmy chimpanzee is for the common ancestor of humans and apes, I believe that it cannot be taken as the best model to the exclusion of the common chimpanzee.

Although the pygmy chimpanzee appears at first glance to be the ideal candidate for modeling the ancestral human condition, close inspection of selected elements of pygmy chimpanzee anatomy and recent discoveries of early human fossils cast doubt on how ideal it is. Recent fossil evidence, from various sites in Africa (Hadar in Ethiopia, and Laetoli in Tanzania), of hominids as old as 3.75 million years indicates that early human ancestors showed a much greater anatomical difference between the sexes than do pygmy chimpanzees. The common chimpanzee, other apes, and modern humans all exhibit greater differences between the sexes in body shape and size than do pygmy chimpanzees. Thus, it may be that the similarity of the sexes in the pygmy chimpanzee is not an indication of its similarity to a generalized primate ancestor but a more recent adaptation.

Problems always arise in trying to read back from a living creature to an extinct one. An animal that lives today may have changed less than some other animal in terms of a common ancestor, but all have changed. And some aspects of each species have changed more than others. Chimpanzees or pygmy chimpanzees may be closer than human beings are to our common ancestor—that is, they may have changed less since divergence. But some aspects of the apes are recent and highly specialized adaptations. For example, both chimpanzees (pygmy and common) and gorillas engage in knuckle walking, an adaptation to a mixed life in the trees and on the ground that allows the apes to have long grasping fingers and still walk comfortably on all fours. No other apes exhibit this behavior, and there is no evidence of it occurring in any of the fossil primates we know.

To begin to do what we want to do—read into the fossil record behavioral interpretations bolstered by evidence gained from our investigations (behavioral and anatomical) of living apes—we need to learn more about the anatomy of humans and of apes other than the pygmy chimpanzee, and to avoid the pitfalls of comparisons. We have to determine which traits are conservative (common to all apes and humans) and which are derived (peculiar to a subgroup of apes, African apes, for instance, and humans).

Such distinctions are absolutely necessary in reaching conclusions about the special affinities of humans with any one ape species. And such distinctions are also a necessary prelude to using living apes to deduce the behavior of our fossil ancestors. ☐

*Pygmy chimpanzees sometimes walk bipedally in the trees, usually when carrying objects or displaying. This adult male, on a horizontal bough eighty feet high, is holding fruit from the boongola tree in each hand.*

# In Search of Ancient Pack Rats

*The discovery of fossil pack rat middens has uncovered a 30,000-year-old environmental record*

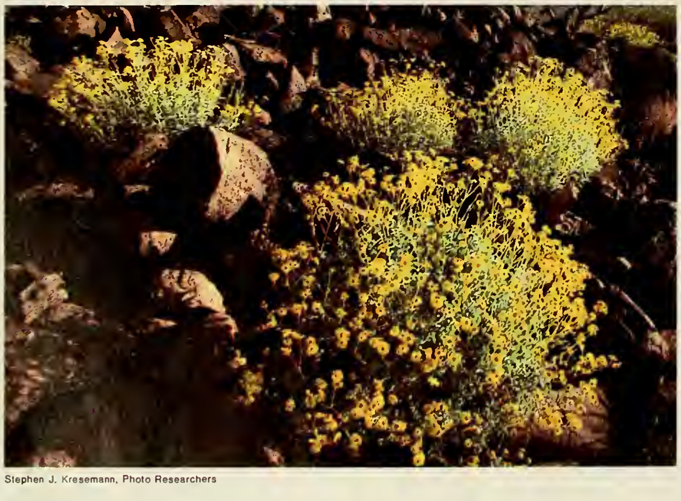
**by Jim I. Mead**

On a very hot day in March, a field party from the Univeristy of Arizona set out to survey the lower part of the Grand Canyon for late Pleistocene fossil sites. Spring was already in full swing at the lower elevations Brittlebush blanketed the talus slopes with orange-yellow bouquets and the rich purple flowers of beavertail prickly pear cactus dotted the rocky landscape. I headed off alone up an unnamed canyon. My plan was to systematically examine the limestone cliffs of the Mauv Formation in search of fossils that would provide a record of life in the Grand Canyon during the last Ice Age. By midafternoon I had located evidence that promised to answer many questions about the Grand Canyon's past.

The last great advance of the continental ice sheets that covered all of Canada and part of the northern United States occurred approximately 22,000 to 14,000 years ago. This period is technically known as the Late Wisconsin Glacial, or more commonly, the last Ice Age. About 14,000 years ago the ice sheets began an oscillatory retreat. As these dominating masses shrank from the scoured and denuded land, plants and animals all over North America altered their existing ranges in response to the new environmental conditions. For thousands of years, environments had remained relatively stable because of the presence of the huge ice fields. But with the warming trend of the late glacial periods, plants and animals had to adapt. The hope of our party was to discover fossil deposits that would help piece together the fate of Ice Age plant and animal communities that are no longer found within the Grand Canyon.

I was searching for the cemented organic residues of pack rat dwellings. There are at present eight species of this medium-sized rodent in the United States. All pack rats have a habit of collecting seeds, leaves, flowers, twigs, bones, and other small objects from within their 300-foot foraging range. Forming an excellent sample of the local biotic community, these items are used for food and for constructing the dwelling in which the pack rat lives. Periodic cleaning by the pack rat produces a pile, or midden, of discarded material. Repeated trampling and urination compact the midden into a hard, cemented waste accumulation. When the wastes are deposited on a more or less horizontal surface, the deposit can be as evenly bedded as a layer cake. If it is located in a protected and dry rock crevice or cave, the midden will be preserved as long as the shelter exists.

Most of the morning was spent pok-



Stephen J. Kresemann, Photo Researchers

*Herbaceous and thorny desert plants such as brittlebush, left, have been common at lower elevations of the Grand Canyon for about 7,000 years. The desert pack rat, right, can tolerate the canyon's hot, dry summers and cool winters.*

Tom McHugh, Photo Researc

ing my head in and among the numerous shelters and rock crevices of the cliff. Occasionally, a large vertical crack would require me to chimney-up the crevice to make absolutely sure that there were no hidden cave entrances or fossils. While hiking along a narrow talus slope 500 feet above the canyon bottom, I spotted the horns of a bighorn sheep barely showing above a dense bush some twenty feet away. Had I surprised this wary canyon dweller? Bighorn sheep are known to live in many regions of the Grand Canyon. Their trails are common in areas I have surveyed. As I crept up to the protruding horns, I found that what used to be a magnificent ram was now a mummified, curled-up carcass. I had no way of knowing how long the sheep had been dead, but because of the Grand Canyon's arid climate, organic remains in a crevice or cave, beyond the drip-line of seasonal rainstorms, will be preserved almost indefinitely.

By noon I had surveyed a fair distance up the canyon. During lunch I saw what appeared to be a small hole at the cliff base of a side canyon. Was it really a cave entrance or just another tempting shadow? Something told me to check it out, if nothing else, just to be consistent about my survey. The ever present echoing call of a canyon wren kept me company as I made my way into the steep-walled side canyon. The two turkey vultures that I had seen early in the morning were now flying directly above me; the sight almost made me wonder what I was getting myself into.

Peering with my flashlight between the fallen limestone blocks, I could see that this was no mere boulder pile, but a cave entrance. I wormed in a little farther to get a better view, my eyes straining to adjust to the darkness. Then I caught it—the overpowering, pungent, yet somewhat sweet smell of fossil rodent urine—pack rats! I never thought that such a musty odor would get me so excited. I quickly squirmed into the cave and peered around the small room. Pack rat middens were lying all about the room. But how old were these middens? Pack rat middens that are still being formed are common throughout the Grand Canyon. With my chisel and geologist's hammer, I broke off a chunk of a rock-hard midden and closely examined the protruding contents. There were hundreds of seeds and twigs of juniper and singleleaf ash. Feather fragments and bones of the California condor, along with a camel tooth, were indicative of a biotic community long since gone from the area.

With permits from Grand Canyon National Park headquarters, I returned many times to study the middens in detail. The cave, now named Vulture Cave, was mapped to locate the middens and each was examined in cross section to determine individual stratigraphic complexities. Each individual layer was sampled and packaged for transport to the Laboratory of Paleoenvironmental Studies in Tucson.

In the lab, individual layers were placed in water to dissolve the cementing urine. After a few days, the urine-saturated water was poured through a fine strainer. Repeated washings disaggregated all the midden components, which were then oven dried. Handpicking segregated the fossils (bones, seeds, leaves, and a host of obscure items). The final task of identifying all the fossils was done by using plant and animal comparative collections located on the University of Arizona campus. Many of the fossils were so well preserved that they could be recognized as belonging to living spe-

*Turkey vultures moved into the Grand Canyon 6,000 to 7,000 years ago. Two of the birds circled over the author as he traversed a steep-walled canyon and led him to name the cave he discovered, Vulture Cave.*

cies. About five to ten grams of plant material were sampled from each midden layer and radiocarbon dated. This provided a precise age of when each midden layer and its fossils had been deposited in the cave. The analyses and radiocarbon dates of some twenty middens from Vulture Cave revealed a fascinating glimpse into the past.

The Grand Canyon's present plant and animal communities are a guide to understanding the changes that occurred during and since the Ice Age. Today, the area around Vulture Cave (2,120 feet above sea level) and most of the lower elevations of the western reaches of the canyon are dominated by herbaceous and thorny shrubs common to the Mohave Desert: creosote bush, brittlebush, sandpaper bush, cat's-claw acacia, and numerous cactus species. Animals that live in this plant community can tolerate the hot, dry summer months and the relatively cool winters. The desert and white-throated pack rat, bighorn sheep, desert tortoise, chuckwalla, collared lizard, desert spiny lizard, and side-blotched lizard are common. These desert species gradually drop out at higher elevations and are replaced by woodland forms at approximately 4,500 feet. Utah juniper, shadscale, Utah agave, and bear grass, to name a few, become the dominant plants. The Mexican and Stephen's pack rats are present, along with the western fence lizard, which is tolerant of the cool temperatures of the woodlands. The canyon rims at 6,000 feet are dominated by piñon-juniper woodlands. The bushy-tailed pack rat, mountain lion, mule deer, mountain kingsnake, Abert's squirrel, black bear, porcupine, and Merriam's shrew inhabit these cooler woodland and pine forest regions. Bighorn sheep are also present, but in fewer numbers than at the lower elevations of the canyon.

The fossil pack rat middens from Vulture Cave provide a detailed environmental record from 23,000 to 11,000 years ago. They indicate that prior to the last Ice Age maximum, the slopes around Vulture Cave supported a juniper–single-leaf ash woodland, along with certain characteristic desert species. The closest woodland today is some 2,800 feet higher and seven miles farther north. The animals from this early glacial period are not well known except for the desert tortoise, collared lizard, and the desert shrew, the same taxa that are present in the lower Grand Canyon today.

The full glacial period was a time of slight change in the Grand Canyon. The juniper woodland community, reaching the beaches of the Colorado River, contained blackbrush and shadscale as codominants, while single-leaf ash seems to have been more restricted. The animals living within that more or less xeric woodland included the marmot, which at present does not inhabit Arizona, and the Mexican, or longtail, vole, presumably the species that is now restricted to the canyon rim forests. The desert element was represented by the side-blotched lizard and sandpaper bush.

In the western Grand Canyon the last glacial period (approximately 18,000 to 10,000 years ago) saw a return to the early glacial community with single-leaf ash again codominating with juniper in the woodland. Late glacial age animals are well represented in Vulture Cave's midden fauna. The desert fauna included the desert tortoise and chuckwalla; woodland animals included the porcupine, marmot, and vole. Mule deer, bighorn sheep, pronghorn, and a now extinct camel browsed the vegetation near Vulture Cave, while the California condor soared through the canyons searching for large carcasses. And large carcasses there were. Besides the already mentioned large herbivores, a nearby fossil deposit, Rampart Cave, contains evidence that the extinct Shasta ground sloth and Harrington's mountain goat also roamed the lower Grand Canyon.

The same arid environment and the protective caves that preserved the pack rat middens also have mummified the dung of some of these extinct herbivores. Rampart Cave is one of seven caves in western North America that contain the dried dung of the Shasta ground sloth. Being made of organic material, fossil dung can be radiocarbon dated. Paul S. Martin dated numerous dung balls that he found on the surface of the Rampart Cave deposit (see "Sloth Droppings," *Natural History*, August–September 1975). He discovered that the sloth last voided in Rampart Cave 11,000 years ago. Richard M. Hansen of Colorado State University recently examined plant fragments from the Rampart Cave sloth dung. He found that the sloths browsed on globe mallow, Mormon tea, cat's-claw acacia, and mesquite. Analyses of pack rat middens from Vulture and Rampart caves indicate that globe mallow and Mormon tea were probably common constituents of the local community for at least 30,000 years. All plants eaten by the Shasta ground sloth still grow in the area of the cave today. Based upon its diet, the Shasta ground sloth could live in the Grand Canyon today. Martin believes that Paleoindians hunted the sloth to extinction 11,000 years ago.

Precisely when the Ice Age came to an end in the Grand Canyon is not certain. Based upon the Vulture Cave record and a few other nearby pack rat middens, some woodland plants and animals began to disappear from the lower elevations of the western canyons about 14,000 years ago. At this same time, desert species, most of which were already there, began to increase in abundance. Other pack rat middens located near Vulture Cave indicate that the last plant vestige of the Ice Age woodland was the juniper, which persisted near the cave until about 8,500 years ago. The end of the Ice Age was apparently not catastrophically abrupt, but more or less a gradual change or a series of minor, abrupt changes in the environment over a period of some two to four thousand years. The Vulture Cave record is largely absent for the period between 10,000 and 2,000 years ago. The middle Holocene, less than 7,000 years ago, was certainly a time of desert vegetation, as it is today. The woodland taxa typical of the glacial period had retreated to the higher portions of the Colorado Plateau bordering the Grand Canyon. A ring-tailed cat den and a pack rat midden, both located in Vulture Cave, preserved a detailed record

*The entrance room to Vulture Cave is located 2,120 feet above sea level. Fossilized pack rat middens were found lying all about the floor of the cave. Analysis of the urine-cemented middens revealed them to be up to 30,000 years old. Among the items identified in the middens were seeds and twigs of former woodlands, feathers and bones of the California condor, and a camel's tooth. The environmental history of the Grand Canyon is now more complete because of these finds.*

Arthur M. Phillips, III

Hans Wendler, fpg

of the local fauna and flora of the late Holocene. The local desert community contained at least eight species of lizards, including the banded gecko, chuckwalla, and the poisonous Gila monster. At least ten different snakes inhabited the local desert including the milk snake and rattlesnake. Turkey vultures had moved into the canyon.

That hot sunny day's hike in the Grand Canyon was a success. I had discovered a dry cave that had preserved a detailed record of the animals and plants that inhabited the western Grand Canyon reaching back in time 30,000 years. Since that inspiring find, I have traveled many times to the Grand Canyon. Each time while I stand on the rim overlooking the canyon, I try to visualize what it looked like when woodland reached clear down to the Colorado River and condors soared below the rim. On my last trip to the canyon, I watched a white-throated pack rat run from a cactus to its den, and wondered what treasures of the present biotic community it was packing away in its sheltered den to be preserved for some future paleoecologist. ☐

# Asia

## Mother of Civilization

Asia is the unrivaled continent of superlatives: it has the largest land area, the greatest number of people, the highest mountains, the first civilization, the first writing, the first alphabets, the earliest agriculture, the first cities, the first codified law, the oldest continuous monarchy, and the oldest ethical faiths in the world. Some would call Asia the Mother of Civilization.

A new, permanent Hall of Asian Peoples, opening in October at the American Museum of Natural History, was designed to display some of the material evidence for Asia's cultural priorities. At the same time, the hall will emphasize who the Asians are and promote better understanding of the traditional cultures of Asian peoples from Turkey to Japan, from the arctic rim of Siberia to Cape Comorin at the southern tip of the Indian subcontinent. These traditional cultures have been enormously attractive to the West from the days of Alexander the Great to the present-day tourist seeking old splendors under modern veneers.

The West has been drawn to Asia not only by its wealth, rich crafts, spices, and other material exotica, but also by its particular ways of viewing the world—most of them so different from Western beliefs that they raise many questions. For example, why do the Indians arrange society in castes? Why did traditional China emphasize the past as the model for the future, whereas ancient Judaism stressed the present as preparation for the future? Why does Zoroastrianism conceive of the world as a struggle between good and evil, insisting that fire, earth, and water be left unpolluted by man? Why do Tibetans have both polygamy and polyandry? What is ancestor worship and what are the five basic Confucian relationships?

No single museum hall can answer all these questions, but it can present an overall Asian self-view. The basic Asian view of life is the underlying focus of the hall. Within that fundamental theme, smaller motifs run from section to section. These are Asian ideologies, social organization, authority, economics, technologies, pertinent languages, and aesthetic styles. But before Asian outlooks can be appreciated, the geography of the continent must be understood.

What is Asia? Most importantly, it is a landmass so vast that it makes Europe seem a mere promontory. The distance from Aden on the southeastern corner of the Arabian Peninsula to the Bering Strait in the north is 6,500 miles, more than 4,000 miles separate Cape Comorin from the Polovstrov peninsula on the Arctic Ocean, and from Baghdad to Peking it is 3,800 miles as the crow flies.

Asia fronts on three oceans and more than twice that number of seas, but despite this vast coastline, most Asians are landlocked and land oriented. Neither the Japanese, Chinese, nor Indians were seafarers. Not until late in Chinese and Japanese history did sea travel become important. It was the Koreans who braved the seas of China and Japan to transport merchandise and monks between the two countries. Similarly, Indonesians and Malays were often the sailors who brought Indians and Indian produce to Southeast Asia. Only the Arabs of western Asia made seafaring a critical part of their activity. Arab dhows reached Canton and traded as early as the eighth century A.D., and the ancestors of the Arabs carried the trade of Rome to India. A Roman seaport has been found at Arikamedu near Pondicherry on the Bay of Bengal.

Asia lends itself to isolation not only by reason of its great size but also because of the particular way it is divided by mountains and deserts. Mountains dominate Armenia, Georgia, and Azerbaijan. The Caucasus has always been a land of isolated, fiercely independent people who fought through the centuries to preserve their way of life in spite of efforts at conquest.

Land routes were the avenues of communication that counted for the Asians. The Chinese looked beyond their Great Wall to Turkestan via Dzungaria; the Indians looked to the Khyber and Gomel passes, on the border between modern Afghanistan and Pakistan; and the Persians to the northern roads from Turkestan to the Caucasus and the passes of the Zagros Mountains. But their own borders have had special meaning for Asian peoples. These lines were very important not simply as markers of territories but also because the people within the borders had ultrastrong feelings about their own lands. Chinese traveling abroad, for example, took a risk, for the Chinese want to be born and buried in the homeland of their ancestors. China, Korea, Burma, Thailand, Tibet, and Japan have all followed policies of isolation at one time or another, not only to keep foreign influences out but also as their peoples' expression of an inner devotion to the homelands on which their happiness seemed to depend.

# The Near East

In many ways, Westerners find the people of the Near East more difficult to understand than those of any other culture area of Asia. There are two good historical reasons for this: Islam and the Turks. From the early sixteenth century until 1918, the Turks ruled much of southeastern Europe. Most of that time their empire controlled the whole North African coast and many islands of the Mediterranean. No one familiar with the history of Europe, particularly in the sixteenth and seventeenth centuries, can deny the enormous influence the Turks had on that part of the world. Their control of the eastern Mediterranean made trade with India and other eastern lands difficult, if not impossible. Expansion into Central Europe brought Hungary under Turkish control, and Vienna itself was beseiged. The most important seige took place in 1683 and is symbolized to this day by the crescent-shaped rolls found in all Viennese coffee shops. It took the combined powers of Poland and the Hapsburg monarchy to drive the Turks back, a victory that in European eyes represented the triumph not only of the Christian West but of the forces of good over those of evil.

The fact that polygamy was practiced in the Turkish Empire, that there were harems, despotic rulers, and an exotic aura to things "oriental," whether they were spices, bronze hanging lamps, exquisite rugs, belly dancers, or bedizened camels, emphasized the differences between East and West.

□

Islam, the dominant faith of the modern Near East, is not only a religion; it is a way of life. The Word of God, as conveyed to men by the Prophet Muhammad and written down in the Holy Koran, is not altogether a doctrinal statement. It stipulates what the individual should be from birth to death, not directly in terms of the ideal, but as a practical statement rooted in the experience of living in the Near East. The remarkable thing about the Koran is that its practice leads eventually to that ideal.

For millions of people, Islam is simple to follow, and the promise of salvation it extends to those who follow it goes far beyond elaborations and rites. But to Europeans, the idea of the oneness of God, Islam's basic theme, subverts the Christian principle of the Trinity, for it denies the divinity of Christ although almost paradoxically accepting the role of Jesus as a prophet. Furthermore, the Koran does not oppose polygamy and indicates that a Muslim, that is, one who has submitted to God, has a duty to oppose non-Muslims.

To the West, the Koran was far from a holy book; it was a statement of paganism.

□

Nearly 80 percent of Near Eastern people are involved in agriculture, so that populations concentrate heavily where agricultural activity results in large production. Thus cities such as Cairo, Damascus, Medina, Baghdad, and Shiraz are not only famed centers of religion, learning, and commerce but also viable centers in the areas of richest agricultural production. Such cities attract the products of pastoralists and here the hair, hides, meat, and rugs of pastoral enterprise are exchanged for manufactured objects and agricultural goods.

The characteristic city of the Near East is likely to depend for its wealth on commerce. Except for oil, the Near East generally lacks natural resources, and its oil has only recently been exploited. On the other hand, its geographical location between Inner Asia, Africa, and Europe gave the Near East a great advantage as a middleman. The local merchant class, dealing in products indigenous to the Near East or from regions far beyond, included wealthy patrons of a cosmopolitan culture that extended much farther than the confines of their own cities.

Connected, of course, with commerce are the splendors of Near Eastern craftsmanship. Through the

*Bronze bull head from Persia (ca. 1500–1300 B.C*

generations, families have generally carried on urban crafts. Characteristically, the shop is a retail outlet, a factory, and a place of residence. The crafts usually segregate along given streets or areas; thus streets of copper wares, rugs, basketwork, ceramics, jewelry, and cloth are an integral part of the typical Near Eastern city.

Near Eastern cities have specific architectural features that characterize them almost everywhere. The Islamic city usually centers on the mosque. It is not unusual to have a great central mosque and smaller ones spread throughout the city. Associated with the mosques are the religious schools. Near the great mosques are the central bazaars, or markets, which include storehouses and shops separated according to merchandise.

Beyond the bazaar are residential quarters divided by ethnic or religious affinity. Thus there may be separate quarters for Coptic Christians, Jews, Armenians, and Assyrians. Many of these quarters are walled, and within their confines people carry on the basic traditions of their own way of life. Outside the residential zone and the city walls are the vast cemeteries; many are concentrated around the tombs of saints or holy men and act as statements of mortality.

□

Government in the past depended on the power of individuals or royal houses to impose their will on the countryside. It is not surprising therefore that the citadel, a fortification usually on a natural elevation, was often the symbol of government. Near the citadel, even perhaps surrounding it, was the royal city, which included the monarch's palace, the residences of the court, and the barracks for a military bodyguard.

*A silver Armenian flabellum, or fan, with bells*

Rulership in the Near East has been closely affiliated with religion. This was no less true in King David's day in ancient Israel than in the traditional Islamic country. At the heart of government is the *ulama*, a council of wise men representing various backgrounds, all of whom are trained in religion and can give advice on government. In some sense the council represents a link between the people and the leaders.

The Koran places great emphasis on the behavior of the individual. Everyone, whatever his or her secular status, is equal before Allah. Thus the judgment of the council is as much a comment on the individual as it is an interpretation of the Koran. It is not society that is responsible for the individual's actions, as Western man might argue; it is the individual himself. Accordingly, self-will, freedom of choice, and personal responsibility are as much a part of the Muslim's world view as they are for Christians or Jews.

□

The largest percentage of the population of the Near East lives in the villages. Basically these villagers are peasants. Much of the village land, however, is not owned by the villagers but by the government or by landlords. High rentals and taxes and the vagaries of the seasons, which traditional technology could not deal with, have made village farming difficult. The villager is rooted to the land. Movement to escape difficulties is possible for the nomad but almost impossible for a villager. In consequence, villagers are exploitable, and more than any other group have been the most poorly off, as they have been throughout Asia as a whole. For this reason land reform has been one of the major developments for the revolutionary governments that have emerged since World War II.

The typical village is a group of mud-walled, generally flat-roofed houses, some two-stories high, irregularly placed about one another, and set within a walled compound into which animals can be driven in the evening. Groves of trees—date palms in the south; almond, walnut, pistachio, and poplar trees in the north—are part of the village landscape, providing both shade and fruit. The house usually consists of a kitchen, two sleeping rooms (or one divided sleeping room); a central social, or reception, room; storage rooms; ovens; mangers; perhaps a tower for pigeons; and sometimes a well in the courtyard.

The village is set in the midst of the fields. Because inheritance practices dictate that a man will bequeath some share of land to all his sons, the land becomes fractionalized; often a man may work one large field near the house and three or more much smaller ones scattered throughout the village holdings. A village mosque and perhaps a small schoolroom are the public buildings. The village well provides both water and a place for the exchange of gossip. Villages were once self-sufficient, especially when village potters, weavers, and smiths provided the necessities. Today, of course, manufactured goods produced by national industries, the use of money as the medium of exchange, and the pressure to grow

*Silver hair cones, from Oman area, filled with scented wool or cloth*

market crops have greatly reduced village self-sufficiency.

□

Pastoral nomads are widely found in the Near East. They fall into two broad economic groups: desert Arabs who move seasonally across the Syro-Arabian desert, and mountain pastoralists who seasonally ascend and descend the mountain slopes, particularly those of the Zagros Mountains in Iran. The desert group emphasizes camels and some horses; the mountain group emphasizes sheep, goats, and cattle. Both groups place great importance on the abilities and prowess of the individual. Chiefs and sheiks retain their authority when they are successful as arbitrators, warriors, and possessors of economic wealth. Egalitarianism is particularly important, for the focus on the individual requires a role for those deserving a say in affairs. Chiefs thus spend a considerable period of time in consultation with the representatives of the men of the group.

In social organization the characteristic family is dominated by the oldest male, and it is through his line that inheritance passes. Among the Arabs, all married sons ideally live near the father, and through time a lineage develops relating each generation to a founding ancestor. These ancestral relationships also relate lineage to lineage, resulting in a collection of people who speak the same language, acknowledge the same ancestors, and seasonally follow the same pastoral routes. This large grouping, in turn, acknowledges a dominant lineage, that of the tribal chief.

The residential units of the desert Arabs are the camps in which the famous black tents are found. Made of goat and camel hair, the tents are divided into two parts—the one on the left for women, that on the right for men. Although women do the cooking, the men take pride in the preparation of coffee for which they have a special brazier and traditional implements. The sharing of coffee with strangers is a mark of hospitality.

The sexual division of labor is quite clear. Women do the domestic tasks; men take care of the herds. Raiding for camels and horses was standard practice among the Bedouin of Arabia; it was a means of regulating herd size and provided an opportunity for amassing wealth, which the normal growth of the herds did not permit. Seasonal movement is fairly strictly prescribed by adherence to traditional routes and pastures in both mountain and desert pastoralism.

□

Many books have been written on the subject of the origins of the religions of the Near East—Judaism, Zoroastrianism, Christianity, and Islam. One thing is clear, no particular way of life was the genesis of these faiths. Quite the contrary, it was the mixture of many cultures that provided the setting for the birth of the ideas leading to monotheism and the relationship of man to a single God. The early civilizations of the Near East are marked ideologically by a pantheon of deities, all of whom, in one way or another, share the powers of nature. They created the world and all that is in it. Then man himself was created to work for the gods who disdain the daily activities of seeking subsistence.

□

The most important development in the Near East after the division of the Roman Empire and its gradual demise was the appearance of Islam. The Prophet Muhammad (A.D. 570?–632), founder of the Muslim religion, was born in Mecca, in western Arabia. At the age of six, he lost his mother but, continued to live, apparently as a shepherd, close to his birthplace. Later in his youth it is thought that he worked on caravans traveling south to Yemen or north to Syria. He married a widow, Khadija, fifteen years his senior and active in the trade of which he was now a part. Apparently, even as a boy Muhammad had dreams of events difficult to interpret. He seems to have been a thoughtful, introspective person given to quiet contemplation of his world. It was a quarrelsome, warlike world, basically pagan and caught in the failings of the wornout empires of Sassanian Persia and Byzantium Rome.

It is certain that Muhammad found in the mountains surrounding Mecca the solitude necessary to give his thoughts focus. Just as Zoroaster perceived his vision of Man and God in the solitude of the desert, as Moses talked with God on Mount Sinai, and as Jesus saw the whole earth from the mountaintop in the wilderness, so Muhammad on the mountain Hira had a vision of the Archangel Gabriel and heard the Word of God. Filled at first with self-doubt and fearful of dreams of self-deceit, he remained silent while he wrestled with his convictions. At last he realized the reality of what had happened to him and began to preach of the oneness of God and his universality.

He preached of a final day of judgment; of man's individual responsibility for his own conduct under God. He required of all those who submitted to the God of Islam that they follow the teaching of the Koran by professing the Faith, the revelations of God that Muhammad affirmed as God's prophet. Fundamental to this teaching were five basic moral and ritual duties: to observe the Faith; to pray daily (there are five traditional times for this—sunset, night, dawn, noon, and midafternoon); to give alms out of mercy and charity; to fast during the daytime of the month of Ramadan, the month when the Koran was revealed; and to make a pilgrimage to Mecca (hajj) once in one's lifetime.

Mecca was a center of paganism in those days. Even the Kaaba, the Muslim holy of holies, was a pagan shrine. Because so many pilgrims came to this pagan center, its merchants prospered. Muhammad's antipagan preaching enraged the commercial rulers of the city, and they made every effort to stop him and his increasing number of followers. In the year 622 Muhammad and his followers fled to the city of Medina, a handsome place set in the midst of a date palm oasis. Muslims count their era from this hegira, or migration, from Mecca.

The years that followed were years of further preaching and of military campaigns that culminated in a return to Mecca in 630, which, as the place where the Word of God was heard, became a holy city. Now the band of converts grew and became a brotherhood to which Muhammad preached the laws governing the relationships between men and women under God. By the time he died in A.D. 632, much of the Arabian Peninsula had been converted to Islam. The government was no longer secular, and Islamic and political leaders had to submit to the authority of religious law. In fact, the head of the Islamic state was the Caliph, or defender of the Faith. To this day Koranic law influences government among the Muslim nations of the Near East.

After Muhammad's death a division occurred in the leadership between those who thought that caliphate succession should be selective and not hereditary, the Sunni, and those who felt that it should be hereditary. The latter picked Muhammad's nephew and son-in-law Ali and took the name of Shi'a, or partisan of Ali. Ali was murdered by the Sunni; later his sons Hasan and Husain were also killed. Ali's tomb at Najaf and Husain's at Karbala, both in Iraq, are among the holiest shrines for the Shi'ites. Shiism took hold in Iraq and, most notably, in Iran. The concept of the Imam, presumed to be a blood descendant of the line of Ali, assumes various forms in Shiism. Some believe that the Imam is divinely appointed and has succeeded Muhammad himself. Others believe in a second coming of a Mahdi (guided one).

Arab unity gave the Muslims a military capability, which, coupled with ever increasing numbers of converts from other regions, made possible the rapid conquest of kingdoms to the east and west. Their western expansion came to an end at the Battle of Tours in France in 732, one hundred years after Muhammad's death. After conquering Sind in the east and the southern Punjab in India, the Muslims seem to have run out of steam. All of the Near East except western Anatolia and Armenia was under Muslim rule.

□

The history of the various countries of the Near East is one of invasion, particularly by the Turks and Mongols; of efforts to throw off the rule of the various dynasties; of periods of great cultural flowering; but never of a unity like that of the early years following the death of the Prophet.

Historically there seems to have always been an interplay between the pastoral nomadic discovery of self-identity and the sedentary farmers' need to integrate the old with the new. Whereas the farmer may respond by multiplying the complexity of his world view, the pastoralist seems determined to simplify it. The Bedouin Arabs' use of Islam to account for bad or good luck—and all things beyond their control—demonstrates an adaptability far beyond that of the sophisticated men of Cairo, Beirut, Riyadh, or Damascus, who grasp eagerly at Western ways by day and struggle for a reason to be at night.

# India

For the West the story of the Indo-Pakistan subcontinent is dominated by the history of Englishmen who lived there over a span of more than three hundred years. Although the modern states of India, Pakistan, and Sri Lanka are justifiably proud of their political and cultural independence, for the Westerner it is Great Britain and her institutions that dominate and provide a temporal bridge to an understanding of those countries. All three states grew out of the colonial experience, which saw Englishmen come as traders and stay as rulers. During their stay, they brought the people of South Asia into the modern world. It is no small thing that English is the lingua franca of South Asia or that there are more than 800 words of Indian origin in use in the English language. The European experience in South Asia was by no means one-sided, however, for while English invention and organization brought to an end the feudal and ancient character of life in the subcontinent, Indian philosophy and crafts opened opportunities for new horizons to Europeans and changed the Western world view.

□

Indians have a compelling sense of place within a larger structure. The energizing aspect of this awareness is bound up in the word *dharma*. Essentially *dharma* refers to doing what has to be done in one's life, not as drudgery or a labor of love, but as something necessary and right. *Dharma* was a major factor in Gandhi's peaceful resistance, which was critical in ending British rule in India. Gandhi considered violence not only demeaning in itself, since it endangered the order of life, but also un-Indian because it forced Indians to be what they were not intended to be—people who won their way by means of physical power. In his view, such victories could only lead to more violence. Much concerned with the relationship between morality and truth, Gandhi concluded that they were one and the same. If one acts morally, that is, with the sense of *dharma*, one's actions are truthful and enduring. What is morally obvious does not need the shedding of blood to make it so. In fact, bloodshed would only obscure the truth of India's natural right to be free. A free India was envisioned as made up of many parts, a building constructed of all kinds of materials but where each had an important place, the whole bound together by universal love. One cannot imagine the Mahatma's agony when in 1947 the British left India at last, and Muslims and Hindus slaughtered one another in one of the worst bloodbaths in history.

*Bronze lamp from Nagpur, India, in the shape of a seated bear with a bird's head*

In the sixth century before Christ, a king of Sakya, an Indo-Aryan kingdom in the foothills of the Himalaya, tried to protect his son and heir from the ugliness of the world. He created great pleasure gardens and surrounded the young prince with all that was desirable, all that could provide material happiness. Nevertheless, the prince saw human suffering in various forms, renounced the throne, and wandered over the face of India as an ascetic. After many years he realized that enlightenment would come, not through wandering, but through a struggle within himself. He took up that struggle, and sitting under a bodhi tree, he pondered the circumstances of life and death and the mortality of all living things caught in an eternal cycle of birth, death, and rebirth.

We know that prince as the Buddha, the Enlightened One. His answer to life's riddles—known as the Four Noble Truths—was simple: suffering exists, suffering is caused by desire, suffering can be overcome by the elimination of desire, desire can be eliminated by following the Noble Eightfold Path—a formula of moderation and clear thought, a statement of the role of reason in human affairs. The Buddha preached the application of his truths to all who would listen. After the Buddha's death at the age of eighty, Buddhism took many forms, but at heart it addresses itself to the human condition and a concern for all life.

□

Hinduism, which steadily grew as the most important faith in India from a century or two before the time of Christ, also contains balanced views as to the responsibility of the individual for his own actions. The theme common to both Buddhism and Hinduism is the concept of rebirths. All living things are part of a perpetual cycle of existence, and nothing is lost no matter what form it takes. A basic reality in Hinduism is that man is not only responsible for his own actions but must fulfill the purposes of life whatever his circumstances in any particular rebirth.

There are four goals of man: the pursuit of pleasure, or *kama*; the seeking of material gain, or *artha*; the restraint necessary to do one's duty in life correctly, or *dharma*; and the eventual renunciation of the other three in order to be free from worldliness through a religious objective, or *moksha*. Of these goals, *dharma* is the most important since its emphasis on duty, justice, and rightness affects the pursuit of the other three.

□

The *Bhagavad Gita* is for many the supreme statement

of Indian ideas concerning the place of man within the cosmos. A Hindu classic, it addresses itself to *moksha*, the fourth end of man. At heart it emphasizes the individual's personal relationship to divinity, the consequence of which is to bring that divinity into one's own actions. This enables one to fulfill one's obligations to society in the fullest possible way. The idea that those obligations may involve self-sacrifice is critical; indeed the point of fulfilling one's duty is not to obtain secular advantage or other material gain but to act for the good of society.

The *Bhagavad Gita* is concerned with the sayings of Lord Krishna, one of the most popular gods in India. Anyone studying Hinduism is immediately struck by the multiplicity of deities. Historically, much of that multiplicity was apparently caused by amalgams between the pantheistic Vedic tradition and the local beliefs of tribal India. However, the classical grouping of these gods has three main themes: creation (Brahma), destruction (Siva), and preservation (Vishnu). Paradoxically, each of these powers also contains its opposite. That is, Siva's destruction is also an act of preservation; similarly, Vishnu's preservation involves an act of destruction; and the implication of Brahma's creation is, of course, non-creation. Evidence for these divine paradoxes is found in Hindu mythology. Siva, for example, has consorts who are benign in appearance but also have savage demonic aspects. Vishnu is as capable of bringing fire and flood as of playing the flute for shepherdesses to dance to in some wooded glade. Vishnu's varied selves, or avatars, include Rama and Krishna among many others and are statements of his multifaceted character.

All of Hinduism's gods and goddesses require rites, festivals, and other devotional acts. This is in keeping with the idea of sublimating individual identity to the larger divine. The celebrated yoga (bhakti yoga), in which an essential element is meditation on "oneness," brings the individual into a direct relationship with "divinity." Esoteric Hinduism considers the individual self to be mere illusion in the context of the ultimate oneness, or universal self. To a very real extent every deity in the great tradition of Hinduism is like a key on a great cosmic organ; each produces a particular sound, a resonance if you will, that is a special sonant in the ultimate music of the spheres. The myths and legends gathered around these deities are the basis of narrative embellishments that are familiar to every villager throughout India.

□

By far the largest number of Indians live in villages and the Indian village embodies the India of both dream and reality. Villagers till the soil of their forefathers, hoping for the monsoon rains to come in the terribly hot spring and hoping they will abate at crucial times in the humid summer. The village is dominated by a work ethic in which social recognition is gained through labor and the ability to fulfill one's role in the larger village society. Villages vary in plan and economic emphasis from one region to another. The Bengalis in the east and

*Carved wooden frieze features Indian goddess Gaja Lakshmi being annointed by elephants*

*Goat inlaid with silver and brass from early eighteenth century, north India*

the Tamils in the south are rice growers; the Punjabi of the northwest grow wheat. All try to raise garden crops of chilis, tomatoes, and other vegetables. Practically all village farms use bullocks for plowing and hauling. Cattle are respected for their divine derivation, and meat eating is a rarity, partly because meat animals are difficult to raise and partly because meat eating is generally regarded as an impure practice.

◆

Marriage in India has traditionally been arranged by a go-between who tries to obtain advantages for her employer. As in so much of Asia, marriage involves an economic and social exchange of value for both families. This often means that affairs of the heart are subordinate to the requirements of material considerations.

The position of Indian women is related to inheritance, which tends to go from father to deserving son, and to the customary authority of males in most village affairs. But in fact, the typical Indian village farming family is a work unit in which men and women labor side by side at harvest and seeding time or complement one another's work at other times of the year. Familial decisions tend to be based on discussion between parents, as they are in the West, and are determined by the practicalities of daily life. In terms of their position, Hindu village women tend to be far less bound by custom than their counterparts in either traditional China or the Near East. Older customs, such as child marriage and the isolation of widows, which made a second marriage impossible even though the girl might have been pledged to a boy in pre-adolescent years, have gradually been vanishing from the Indian scene.

Indian society is divided into *jatis,* or castes. The *jatis* can be regarded as functioning parts of the larger organism of Indian society. Each locale, whether village or city, has its own arrangement of *jatis.* A person is born into a *jati* and can never leave it.

In terms of religion, eating habits grade the *jati* according to levels of purity, with the purest being the Brahmans, who are exclusively vegetarian, and the lowest being those who eat meat or handle carrion. The origins of *jati* are not clear. What is apparent is that the number of *jatis* has multiplied greatly in the last three hundred years, mainly in response to changes brought about by contact with the West and by widened communications with the larger India.

◆

Much of Indian history is recounted in terms of north India where the foreigner continually set foot. South India, however, was never completely conquered until the British came with their ships. Village life began there about a thousand years before Christ and expanded into a civilized life as fine cities and towns developed, primarily for trade and royal administration. The Tamil poetic anthologies describe active princes, princesses, merchants, bards, soldiers, musicians, and all the specialized activities common to urban civilization.

The Muslim conquest of northern India, which began with the Arab conquest of Sind in the eighth century and reached its climax with the Mugul empire beginning in the sixteenth century, struck a powerful blow at native Indian traditions. But with a tenacity that still marks India today, much of the tradition survived. Nonetheless, the Muslim-Hindu confrontation has never been peaceful. The anti-Hindu policies of many Muslim governments left a split between different peoples that continues to divide India and the Muslim state of Pakistan. Yet this was not always true. For the Muslim rulers in India had to accept the idea that to rule successfully one had to rule with justice—not simply justice for Muslims but justice for all. Some rulers made valiant efforts to do just that. The most notable was the great Mugul ruler Akbar, a contemporary of Elizabeth I of England and a deeply religious man who listened to followers of many faiths, including Christianity. His policy of tolerance led to greater harmony than had generally been found before in the Muslim state. Akbar demonstrated that given understanding and legal rights, Hindu and Muslim could get along harmoniously.

The Muguls left other, material monuments, as well, the Taj Mahal being the most famous. Based on Persian design, it is significant, however, that the Taj has become one of India's best-known symbols. It is as if the Mugul emperor Jahan had built the Taj Mahal not so much as a tomb for his beloved but rather to provide something beautiful in homage to the Hindustan over which he reigned. That same sense of mission is felt in the history of British India, for looking at the accomplishments of the British Empire in India, one finds that many British officials, realizing that British control could not last forever, wanted to leave an India that would be a monument to their justice and understanding.

# China

To be Chinese is not simply a matter of birth or location, but an acknowledgement that one is part of a stream of consciousness that originated in an idyllic, remote past, has flowed through many vicissitudes down to the present, and will continue to flow in the future. To be Chinese is to be privileged, not because the rest of the world is barbarous, although many Chinese have espoused that idea, but because China is so enduring as to challenge mortality itself.

The outsider gets an initial impression of China as a series of vivid contrasts: the brown green countryside with drably dressed working people counterposed against the brilliant colors of street processions and the interior walls of temples or halls, an enormous mass of humanity contrasted with the solitary figure of a sage in a Taoist painting amidst flourishing trees and pristine, cloud-suggesting mountains, the calm quiet of an old man's bearded face radiating the wisdom of a special maturity, and the singsong wail of the actor in the Peking Opera or the "clack-clack" of a street vendor's wooden cymbals in the early morning. The smells of China are the heavy odors of night soil, fish, and jasmine contrasted with the ephemeral aromas of fine tea, dark timber, and sandalwood.

Above all, there is the endless land. Land is China's measure of value, for what produces food feeds the populace and what is not productive causes famine. There is no escape from that equation in a country with the world's largest population. Those who would understand China must start with the Chinese farmer, his family, and his land. The social cohesiveness of the large family was both an economic and an ideological virtue and caused the Chinese to congregate wherever soil and water allowed them to subsist, rather than to fan out in small households across the landscape. Even in Confucius's day, when the population was much less than a twentieth of what it is now, northeast China was crowded with large families that remained for centuries in one or two places.

With a technology of hand tools and plows and carts drawn by animals or humans, every member of the family had a role. Men and boys broke the soil; women and girls did the seeding and harvesting. In general, every effort was made to keep the large, extended family together.

Directly related to the intimacy of humans and the land was the traditional contempt the Chinese have had for the soldier and the merchant. Neither of these occupations results in foodstuff or the permanence of the family. In the classical Confucian view, the merchant is a nonproducer seeking his own profit. The soldier has uses, but if he is killed far from home, he cannot observe filial piety. Nothing represents China's contemporary Westernization more dramatically than the rise of standing armies and the creation of a military elite.

□

The Chinese sage Confucius lived at a time of great trouble for China, from about 551 to about 479 B.C. It was the latter part of the period often referred to as the "classic age" because of the number of writings important to the Chinese tradition that were composed or compiled by famous men of the time. Confucius appears to have been a thoughtful, observant youth who was increasingly troubled by the civil wars and other problems brought on because the central authority was no longer strong enough to control the warring barons. Basic to Confucius's thinking was the idea that the peace and prosperity of the early part of the classic age had been brought about by ideal rulers who modeled their authority on the natural harmonies of the world. In other words, to bring order out of disorder the people of China had to look back to the time when there had been order. Confucius obtained the books of rites and rituals used by the early rulers and brought them to the aristocracy. He insisted that the ancient rites be observed to the letter. More than this, since a ruler was expected to keep the ideals of the past before him, he must accordingly behave morally toward his subjects. His greatest obligation to the people was to gain their confidence. To do this he necessarily had to keep their needs steadily in mind, just as a father must always keep his family in mind if it is to flourish.

This familial relationship is basic to the Confucian ideal. The family in any individual's life must have a central place. When familial relationships are extended into society and sustained by the same qualities that make them vital within the family unit, the society will be harmonious and the state to which that society belongs will be free from disorder. The Confucian system therefore contains five basic relationships. Three are familial: father to son, husband to wife, and older to younger brother. One relationship is social, friend to friend. The final one relates to the state, ruler to subject. These relationships depend ultimately on mutual respect, but it is a respect that can only come from the self-cultivation of virtue. For those who would rule, the emphasis had to be on education.

An essential ingredient of the familial relationships is filial piety. This refers to the respect of children not only for their living parents but for their ancestors as well.

*Nineteenth-century porcelain watchlions from north Ch*

B

The traditional Chinese concept of self can be depicted as a familial chain stretching between the remote past and the near future. The individual is one link on the chain. He owes his being to the past and is thus responsible for assuring a future for his family line. Since the Chinese family is patrilineal, it traces its descent through the male line. Thus sons must marry and produce male offspring so the family name and property will be perpetuated. The most unfilial thing a son can do is fail to produce sons, for that endangers the perpetuation of the family name and thus denies respect for the ancestors. The ideal Chinese household, according to the Confucian ethic, is one in which many sons and their wives and children live under the same roof.

In point of fact, there was great difficulty in keeping married sons together because they could not all inherit the family land. If the land were divided equally among inheriting sons, each share would become progressively smaller through succeeding generations. A common practice was to award the property to the oldest son or sometimes to the most able one. This son then became responsible for the others. However, the other sons, desiring land of their own, probably moved away to establish homes of their own. Wherever those sons went, they nevertheless continued to observe filial piety for the founding ancestor of the family through ceremonies and virtuous acts designed to honor the family generally, and they raised their children within the familial tradition. From this practice of perpetuating the family name even when living far from their place of birth came that important element of Chinese life—ancestor worship.

*Oxblood porcelain vases of the Ch'ing dynasty (1644–1912)*

"Ancestor woship" does not literally mean the worship of an ancestor as though he were a god. Rather, it is a ritualized way of honoring one's predecessors, involving incense burning, prayer, and offerings before an altar containing wooden tablets on which the ancestral names are written. The altar was either in an individual's home or, in communities where numerous related families resided, it might be in a separate building, known as the ancestor hall, that housed the family records and ancestral tablets. These halls are architecturally splendid community buildings that may contain images of Taoist or Buddhist deities or saints. Here the affairs of the community might be discussed by the village elders. The rich colors—gold on red, gold on black lacquer, soft blues, pinks, and vivid greens—coupled with the lavish use of ideographs and traditional designs, make ancestor halls a striking relief from the rather drab buildings of the typical Chinese village.

□

Buddhism was well established in China by the fourth century A.D. but early on encountered both Chinese ethnocentrism and the deep-seated Chinese belief in the relativity of present life to what was and is. The esoteric aspects of Buddhism as practiced in India, however, did not take hold among the people of China, for ideas of reincarnation and Nirvana were not consistent with the linearities of the Chinese ancestor cult. What did take hold was the form of Buddhism known as Pure Land. This conceives of an infinite number of Buddha worlds, one of which is ruled over by the Buddha Amitabha. This is a paradisiacal world often depicted in Buddhist painting as a place of glorious palaces and splendid gardens where the blessed exist in peace and happiness. According to simple practice one could attain that blessed land by invoking Amitabha by merely uttering his name. The temples and monasteries of Chinese Buddhism were filled with the iconographies of the Pure Land and meditation upon that land was customary.

This manifestation of popular attitudes toward religion marks the story of China after the classic age. Buddhist, Taoist, and Confucian beliefs became all mixed up with Chinese local beliefs in ghosts, spirits, and mythical creations. Dragon lore originates in the observance of the vitalism in nature that is central to Taoist belief, and soon there are dragon kings, boats, deities, and a dragon of the sky that chases the sun and moon at the New Year.

To face the realities of this world the Chinese enlisted a host of supernatural helpers. For although man is indeed the link between heaven and earth, past and future, there is no question that the factors of fortune and misfortune are the chance elements in an otherwise logical world. The famous I-Ching, or *Book of Changes*, acknowledged for thousands of years as one of the most important books on man's place in the cosmos, deals directly with the factor of chance. The I-Ching, in effect, not only measures chance but by so doing sets forth predictabilities far more meaningful than the law of averages of the West, for they relate to wisdom itself. No wonder that popular Chinese religion uses the hexagrams of the I-Ching almost as frequently as gold-on-red characters for good fortune and happiness.

*Ho-tei, the Chinese god of good fortune (nineteenth centu)*

# Japan

Japan is the end of Asia, beyond it lies the vast Pacific Ocean. Situated on the eastern fringe of that great continent, Japan through its culture expresses both its rich debt to the great traditions of China and India, which historically have influenced it, and its own indigenous mastery of cultural self and of what it has received. Japan was one of the last regions in Asia to receive civilization. Its culture is peopled with historical ghosts that roam the landscape—for example, winged creatures with human faces like the *tengu*; little devils like the *oni*; and lonely shades of the mountains. The country has had a powerful military tradition and a monarchy that has endured to the present. It has a rich literature with a great tradition of poetry.

The people of Japan were often thought by others to be less the originators of ideas than their instruments. The Industrial Revolution found ready acceptance in Japan, the most industrialized Asian nation. That development is a tribute to native genius. Modern Japan presents a picture of slick and efficient enterprise.

◆

Japan is a beautiful country, consisting of four mountain-crowned islands surrounded by ocean and sea and extending over fifteen degrees latitude. Its crescent shape links it with Korea and eastern Siberia, yet it touches neither. Subject to earthquakes and tidal waves, Japan is no quiet, sea-girt paradise, but a land of great contrasts: high mountains and stony beaches; volcanoes and sandy littorals; rock promontories in the sea and mossy stones in clear streams; pristine green forests and untold miles of rice paddies. By day Japan feeds the eye and provokes the mind; by night there are elements of darkness and light that motivate the sensitive to remember the past.

◆

Consciousness of the past is an element of the Japanese spirit. Unlike the West, where conceptions of earlier times are dominated by great figures such as Pericles, Alexander, Charlemagne, Elizabeth I, and Napoleon, the Japanese tend to think of the past in terms of events and of dynastic families. They have their own pantheon of great men—warriors, rulers, priests, artists, and thinkers—but almost all of these individuals are regarded as products of a time rather than creators of it. In this sense, history for the Japanese has a kind of logic that emphasizes durability through time rather than uncertainty and the vagaries of direction caused by individual personalities. Like the earthquake-prone countryside, Japanese history sways with the movements of events but remains paradoxically stable. There were no foreign rulers, no Mongol or Manchu dynasties. But there has been repeated struggle between local rule and centralized government; opposition between parties of secular and of sacred authority. There are conservative champions of tradition and progressive proponents of newer ways of doing and thinking. Yet one senses in Japanese history evolutionary rather than revolutionary qualities.

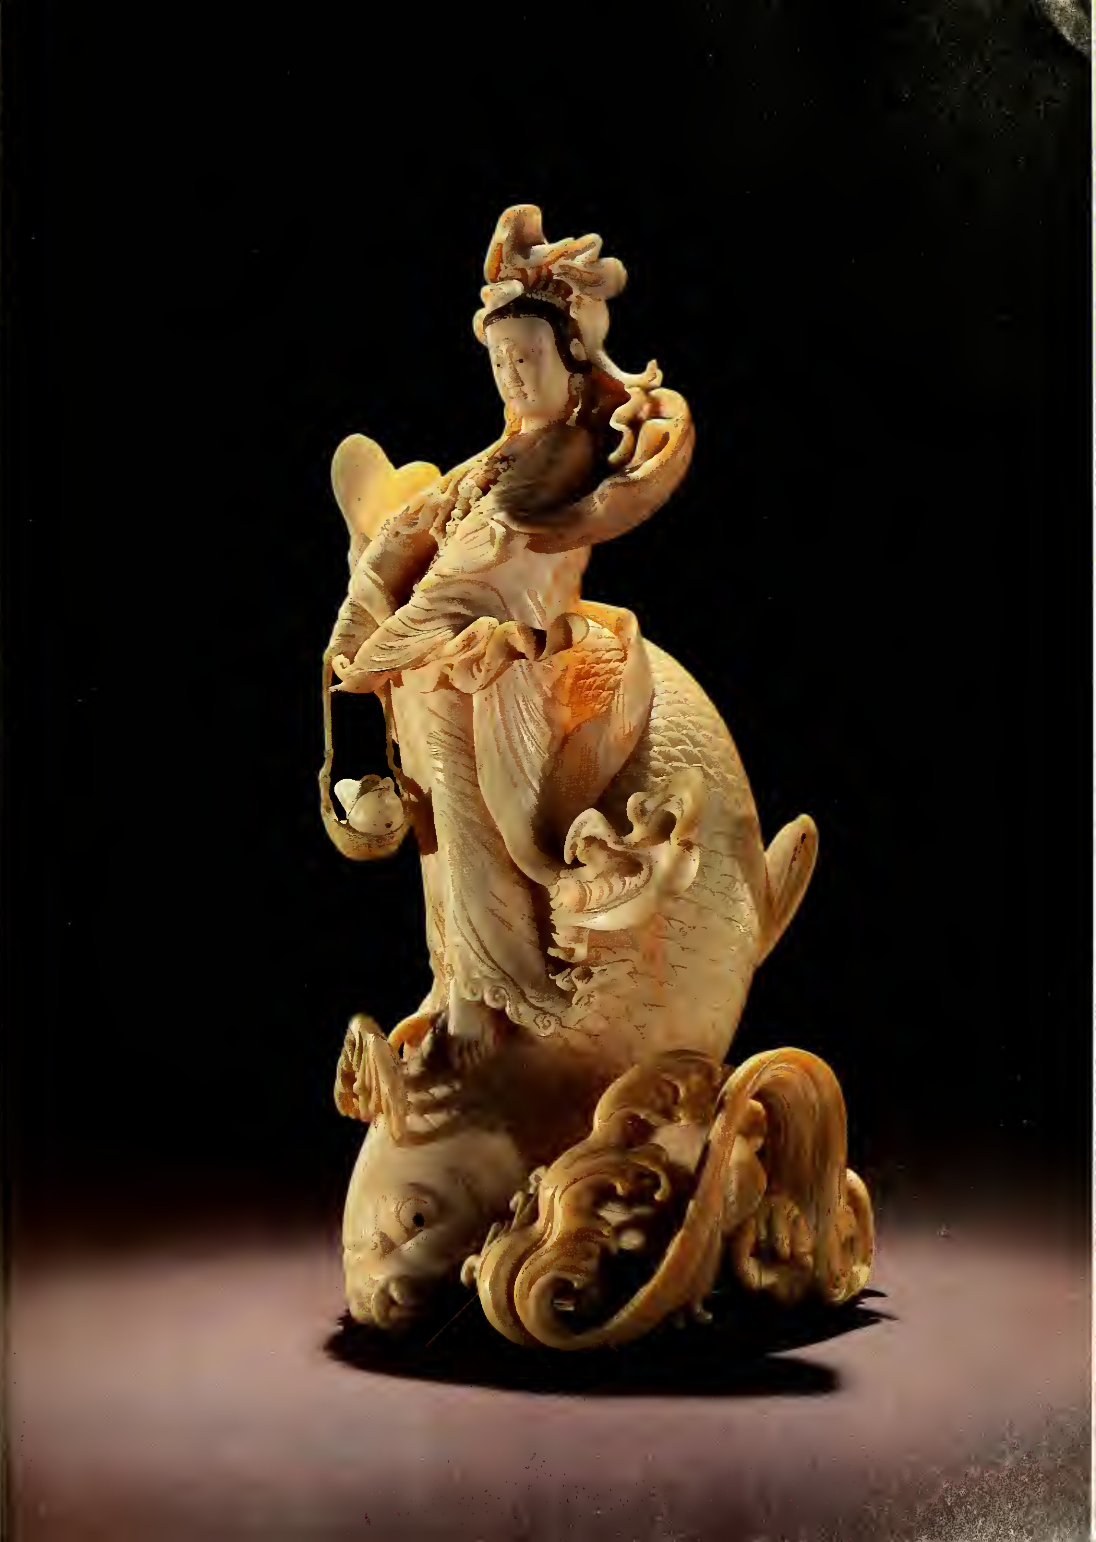
◆

About A.D. 1200 some four hundred years of Japanese feudalism began. Ostensibly receiving their authority from the emperor, the local shoguns, or military governors, operated fairly much on their own volition. This warrior society, which was the dominant force of medieval Japan, can be summarized by the term samurai (one who serves). The samurai were characterized by courage, military ability, intense loyalty to leaders, and a personal pride that often amounted to arrogance. As provincial warriors they presented a great contrast to the courtiers of the imperial court in Kyoto. The wars, intrigues, and successions involving the samurai are the basis of some of the most popular stories known to the Japanese. Like the cowboy stories of the American West, many modern Japanese concepts of history are samurai centered.

Despite the emphasis on combat during the long period of military domination, many shoguns and their provincial governors (*daimyo*) were patrons of the arts. Painting, like that of the world-famous fourteenth-century landscape painter, Sesshu, and architecture, such as that of the Gold and the Silver Pavilions, are outstanding. The No theater, the tea ceremony, and even landscape gardening gained great prominence. Whereas in the previous Fujiwara court there had been an increasingly rigid aesthetic etiquette, the feudal age was looser and permitted innovation.

The tension between local self-rule and central authority had a paradoxical quality in that no matter what individual convictions were held, everyone acknowledged the divine roots of the imperial line. The natural tendency of the Japanese was toward unification, not separatism. This played a role in the success of a series of powerful leaders in eventually reunifying and

*Ivory carving of Kwan-Yin, the Japanese godde*
*of mercy and protectress of fish and fisherm*



ruling Japan. Of these leaders, the best known were the Tokugawa, a family that controlled Japan from 1603 to 1867. An active class system placed the samurai at the top, followed by farmers and artisans, with merchants at the bottom. Fearing a growing European presence and the challenge of Christianity to Japanese values, all but a few Europeans and Chinese were excluded. This policy of exclusion effectively isolated Japan from the West for more than two hundred years. But those were years of considerable development: cities and towns grew, agriculture expanded, and money became the means of exchange.

The cultural innovations of the feudal period flourished as never before. Puppet theatre, Kabuki, and haiku poems illustrated with woodblock printing appeared. Costumes marking rank and occupation and a preoccupation with ornamentation and fanciful calligraphy made even the simplest shop in the market a firm statement of form and color amidst a tasteful riot of decorated street signs, lanterns, parasols, and door posts. This was the Japan of the floating world, of pleasure quarters, of the geisha, of the love suicides. It was a world where Confucian ideals were introduced into government to insure purpose and longevity.

□

The fall of the Tokugawa was presaged by two oddly contradictory factors. Under the Tokugawa the samurai had nobody to fight. While they had high social status and rights possessed by no other social class, they tended to be impecunious followers of lords whose success depended not on arms but on farmers or merchants. Samurai poverty motivated the arts of Zen Buddhism, the tea cult, and the miniature austerities of flower arrangement and landscape gardening. For these arts are not expensive. Rocks, sand, flowers, crudely made tea cups, lonely meditation, and the linking of poetic lines are available to even the poorest person. Refined taste, sensitivity, and the search for a richness beyond the material are all that one needs.

The other factor was the success of the merchant group, the lowest within the class structure. The growing cities and towns, the tight controls of Tokugawa administration, and the fundamental social and political order of the day were ideal for the role of the merchant. The exchange of goods and services by merchants was necessary if the townspeople were to enjoy the foodstuffs, cloth, metal, ceramic, paper, and wood necessary to city life. The raw materials of the craftsman, the finished products of the artisan, and the markets necessary for their distribution could not be the responsibility of samurai. They were untrained in such matters and considered them socially demeaning. The merchant class grew in wealth while remaining low in social standing; the samurai grew poorer while remaining high in social status. Samurai often found themselves in debt to the merchants and there was acute discomfort in the situation. Unable to handle the growing needs of its people, the Tokugawa shogunate sought reactionary answers, including excessive taxation of the peasantry and military ways to control local recalcitrance.

# JAPAN THE SECOND TIME AROUND

**"The first time Jim and I were in Japan we spent three days there. It wasn't nearly enough time. We promised ourselves we would come back. I'm so glad we kept our promise.**

"We started planning our trip months before we were in Japan. Looking back now, every minute we spent planning rewarded us in hours of enjoyment.

"Even though we never met them, Jim and I feel we have many friends at the Japan National Tourist Organization. They not only sent us guides, timetables and maps, they went out of their way to answer special questions. For example, Jim just finished reading Shogun and wanted to see something connected with the samurai warrior era. JNTO told us we could visit the house of a samurai in Matsue and Hagi. JNTO even helped us arrange a visit with a Japanese family through their Home Visit Program.

"We chose Japan Air Lines because we wanted our vacation to begin as soon as possible. On JAL, we felt we were in Japan from the moment we were welcomed aboard with the traditional bow. Their gracious, thoughtful service was a precursor of our whole vacation. JAL also opened a world of special information to us—lightweight travel handbooks and a Jet-Age language cassette in traveller's Japanese that Jim mastered very quickly. And when we told JAL of our interests in ceramics and gardens, they quickly recommended a tour that highlighted both.

"Our trip has given us a wealth of memories: the tame deer we fed in Nara, the ikebana flower arranging class I took, the village of pottery craftsmen we visited where we both had turns at the potter's wheel.

"Jim and I are back home and planning for another trip to Japan."

**Japan. It's even better the second time around.**

STATE______________ZIP________

Nevertheless, discontent continued to grow until, with the coming of Commodore Perry in 1854, the Tokugawa system began to fall apart. It ended in 1867 and was replaced by the centralization of a new imperial system and the restoration of the emperor to central authority. Brought out of the secluded court at Kyoto, the then emperor, Meiji, moved the imperial seat to Edo, now known as Tokyo.

The two recalcitrants of feudal Tokugawa times, the samurai and the merchant class, brought Japan into the modern world, and in the name of the emperor, made Japan a world power. But in the end their ambitions nearly destroyed the country in World War II.

□

Shinto is the ancient native religion of Japan. The term *Shinto* means the "Way of the Spirit, or Kami." Kami can be conceived of as a benign and elevated spirit in a world of spirits. It is at once personality within things and a quality counter to the destructive, or bad luck, elements in life. Although the Japanese are conscious of a dualism in nature, it is never as sharp as the Yin-Yang of Chinese Taoism. The Japanese myth of creation emphasizes not so much how the world was created as that it was created in order to make Japan possible.

Shinto offers believers a means of relating to the elevated qualities of life. For an artist, it can be the glimpse of a pattern in nature; for the peasant, the well-being induced by rewarded work. Kami can be as specific as the particular shape of a teapot or as general as the good fortune of being born Japanese.

Shinto's relationship to the emperor made possible the state Shinto prevalent in Japan from the Meiji period up to the end of World War II. When the Mongols attacked Japan in the thirteenth century, typhoons drove them away. The Japanese believe these great rescuing winds were sent by the gods. Gods are manifested in Shinto as animistic personalities encompassing the divinity of Japan's kami origins. The winds were called *kamikaze*, "spirit wind," a term later applied to Japanese pilots who flew suicide missions in World War II secure in the knowledge of the divinity of their role. Up to that war, Japan had never been conquered and it seemingly had a mission related to its divine origins. After World War II state Shinto was abolished, but Shinto today is unquestionably still the national faith of Japan. It is a religion to live by, for its purpose is to promote the best in nature. Almost by definition the kami of Shinto is what gives good things their goodness, and what defines the finer qualities of life.

□

Another element in Japanese identity is knowing one's place. In Tokugawa times, class divisions were rigidly imposed. One could not marry out of one's class. Whole patterns of behavior were specified for each class—the depth of bow, the way one looked or did not look, and the language of honorific forms, which differed from class to class. This had the effect of creating a social and economic system in which everyone had a place, a manner, and a daily role with specific goals to fulfill. The Tokugawa social system was a caste system with emphasis on role playing and the maintenance of a characteristic Japanese sense of order. However, there were individuals outside the caste system. Like the untouchables of India, they could do menial tasks and were for all intents and purposes treated as slaves.

□

The Japanese family has been a Confucian family ruled by the father and with descent through the male line. All property remains with the oldest son. This has caused even greater difficulties in Japan than in China because of the extremely limited availability of land. With the growth of population during the Tokugawa period, drift to the cities and towns took place. This required shifts in class status. Brothers or sons of farmers could not be farmers in cities. Thus numerous people attached themselves to merchants and to whatever industries or service units were available. The Tokugawa attempted to force the peasantry to stay on the land but, in the face of population pressures, they were only partially successful. Although filial piety was respected, the Japanese rarely developed the ancestral depth and ritual of the Chinese.

Women in Japan have had little or no authority, even within the family. Subservience to the authority of the oldest male has been the rule. Formality exists between husband and wife, and social activity takes place primarily between males. This has often made the geisha the only woman to whom men could speak openly. Contrary to popular belief, the geisha is not a prostitute, but a cultivated individual trained to entertain with wit, song, and dance. Her role is to provide the otherwise lacking female companionship.

Children, of course, made the family more cohesive. They were raised to fulfill the role already laid out for them: the strict spartan upbringing necessary for samurai, the daily tasks of the farmer, the apprenticeship of the artisan. Grandparents, with their ties to past ways of doing things, gave children a sense of tradition that reinforced the work ethic and above all established the manners and customs of social relationships. Probably no Asian nation, or indeed any nation of the world, had as formal a prescribed manner of social behavior as the Japanese. But with Westernization, the class divisions and, along with them, the strict behavioral patterns broke down. Yet even in the face of change, the Japanese sense of social position remains strong and respect is still displayed to the elderly and those in authority.

## Coda

All cultures have their reason for being. What cultures do, what form they take, and how they survive is the result of how well they function for those who have created them. It then follows that the myriad cultures of traditional Asia are at best the effective responses of particular societies to the circumstances in which they have found themselves. These circumstances include not only adaptation to given ecological situations but also the cumulative responses to traditional histories in which cultural adaptation to indigenously motivated change, as well as integration with outside alien influences, has taken place.

# We Can't Work Miracles Overnight.

**1,765 desperately needy children were on our Waiting List at the end of July.**

## But if you'll give us a little time…

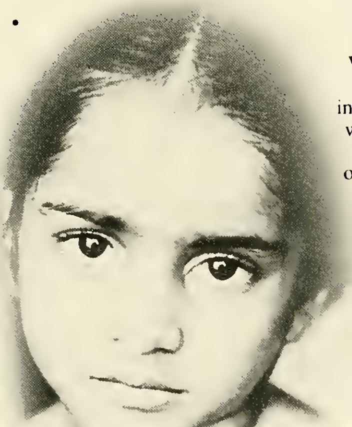
In the countries where Foster Parents Plan works, the average per capita income is only $384 per year. The infant mortality rate is 9.8 percent, almost seven times that of the U.S. Life expectancy averages 49 years, 24 years less than ours. 64 percent are illiterate. There is only one doctor for 13,000 people.

**It's the children who suffer most. Mere survival is often a struggle. Without help most will be trapped by illiteracy and poverty. These are the facts of life. Cruel facts but not hopeless.**

### YOU CAN DO SOMETHING!

With your help a needy child and his family *can* have a better life. ALL THEY NEED IS A CHANCE.

At Foster Parents Plan we believe that *just* sustaining life is not enough. We are dedicated to giving needy children and their families the skills and encouragement they need to take charge of their lives. **Our goal is to help them become self-sufficient.**



**After Mangala's father died, Mangala, her two sisters and her mother moved in with relatives. Ten people are now crowded into a 10 x 18 foot house. No electricity. No furniture. They must carry water from a community tap, a tap that is turned on only two hours a day. Mangala's mother works in a factory, but she cannot earn enough to provide even the basic necessities. Mangala now has a Foster Parent. Others are still waiting.**

### EDUCATION IS THE KEY

We make sure school-aged children can get an education. Their future depends on it.

We can't change lives overnight. And your sense of gratification won't be instantaneous either. Because what we want is truly significant progress. And that takes time and hard work. But over the years, you'll see the progress your Foster Child and his family are making. Because of you.

If you have children, being a Foster Parent offers you a way of showing them how others live and, more important, how you and your children can DO SOMETHING to make this a better world.

The cost? $19 a month. Weigh the cost against the benefits. $19 doesn't go very far in our culture. But with it you can make a significant difference in the life of a needy family overseas.

We hope you will join with us in offering a needy child a better life. Because even sadder than their need is our knowledge that we *could* help. If . . .

**Call us TOLL-FREE**

# The Gardner D. Stout
# Hall of Asian Peoples

In the new Gardner D. Stout Hall of Asian Peoples, a gilded eighteenth-century Buddha sits peacefully in the Japanese section. His serene aspect is in marked contrast to the noisy activity all about him as electricians, painters, artists, preparators, and others work furiously to complete the hall by its scheduled opening date, October 17. This hall, one of the largest and most ambitious in the Museum's history, is the culmination of 14 years of planning and construction and 111 years of collecting.

The Hall of Asian Peoples was a natural outgrowth of the Museum's extensive collection of Asian ethnographic material, most of which was assembled from 1870 to 1920, the golden age of Museum expeditions.

The Jesup North Pacific Expedition (1897–1903) was probably the most important in the Museum's history and certainly the most significant for the new hall. It was organized and financed by Morris K. Jesup, a founder of the Museum, to investigate "the theory that America was originally peopled by migratory tribes from the Asiatic continent." The expedition traversed Siberia, Manchuria, and China, enduring the –50°F temperatures of the Siberian winter, the Boxer Rebellion, and the Russo-Japanese War. One of the expedition's leaders was Berthold Laufer, a great believer in the value of a culture's material objects. He would often walk into workshops and stores and buy everything in sight, including items that were not originally meant to be sold. He even bought out entire drugstores and assembled a representative selection of foods. The Jesup expedition acquired the contents of thirty-five shops and a collection of Siberian ethnographic objects that remains the finest in the world. When a Soviet delegation recently toured the unfinished hall, they were astonished at the range and quality of the objects in the Siberian section. "We have things," says Walter Fairservis, Jr., research associate in the Department of Anthropology and scientific consultant for the new hall, "that even they don't have."

Other Museum expeditions excavated paleolithic sites in the Gobi Desert and other sites in Mongolia, and explored India (bringing back, among other things, much of the portable contents of three Indian villages), Afghanistan, Japan, Tibet, Iran, Korea, and China. The Museum also acquired other large Asian collections, including the Whitney collection of Tibetan religious objects and the Drummond collection of Chinese and Japanese jade and ivory carvings.

Because the Museum did not have a large Asian hall, most of the objects went directly into the storerooms of the Anthropology Department. Fairservis recalls the excitement of "rediscovering the collection" as curator of the new hall. For example, tucked away in a vault under the eaves of the Museum, he found several boxes of extremely rare movable metal type from Korea that predates the Gutenberg Bible by 100 years. And in the Siberian collection, he found a nineteenth-century pictographic love letter written on birchbark.

Fairservis, however, found that the quality and the great number of artifacts were as frustrating as they were rewarding. "There was a lot of stuff upstairs that I just hated to leave out. Less than 5 percent of the collection is actually on display. We have, for example, about 4,000 beautiful Chinese and Indian shadow puppets and room to display maybe a dozen at the most.

"Space was our biggest problem. How do you present all of China in its vastness in something like eighty running feet? We even left out whole cultures. I'm sometimes awed by our audacity."

"The point of the hall," Fairservis continued, "is not simply to show beautiful objects as an art museum would, but to tell a cultural story. This is an anthropology hall, and our approach has been holistic. We want to give visitors an understanding of Asia—its cultures, value systems, cycles of life, social organizations. We

were very careful to get the input of Asian nationals, both as consultants and as artists."

To reflect the diversity of Asia, the Hall of Asian Peoples was designed to wind through numerous corridors, alcoves, and rooms. Visitors with a knowledge of Asian geography, however, will have no trouble finding their way since a journey through the hall follows the two major routes through Asia. One route starts in the ancient city of Samarkand and moves through the Near East, India, Southeast Asia, China, and Japan; the other begins in Siberia and traverses Central Asia and Buddhist High Asia.

"You can actually trace your journey on a map of Asia," says Alex Williams, the hall's designer. He explained that each of the eight principal regions of Asia is set apart by a particular color scheme and traditional architectural styles, and in most sections visitors will hear the traditional music of the area. A separate section illustrates prehistoric Eurasia and the rise of civilization.

One day last summer we toured the Hall of Asian Peoples to see how things were coming along. Picking our way through ladders, stacks of lumber, coils of wire, and sheets of Plexiglas, we suddenly came across a view of seventeenth-century Samarkand, at the crossroads of Asia. The painted scene depicts the overflowing bazaars of the central plaza, shimmering in the heat and surrounded by domed palaces. Kneeling on plywood scaffolding above the diorama, Museum artist Frederica Leser was painting a traditional Islamic pattern on an archway. From her Michaelangelic perch, she talked about her work.

"These elaborate designs," she said, tracing with her finger the complex of intersecting lines and motifs, "could drive one to distraction. It took me quite some time to find authentic Islamic patterns and figure out how to adapt and transfer them to these arches.

"The previous project I worked on involved painting the reptiles in the Hall of Reptiles and Amphibians. As you can imagine, this was quite a change. All of us working on the new hall have had to be versatile."

From Samarkand we moved on to the next section of the hall, which features Islam. Here we ran into Matthew Kalmenoff, an artist who has been with the Museum for thirty-five years, working on a huge painting of the city of Mecca. The scene shows thousands of pilgrims streaming into the holy city at dawn; in the background a crescent moon rises. Kalmenoff has painted, among others, many of the backgrounds in the Hall of North American Forests. He described his technique: "A background must have a feeling of depth and space. I break the painting up into a progression of color planes extending to the horizon. This gives the feeling of looking off into the distance."

Kalmenoff then showed us one of his completed paintings, the background for an exquisite nineteenth-century Chinese wedding chair inlaid with kingfisher feathers. "You don't want the background to compete with that chair," he said. "You can see—look closely—how I have broken the colors into dots to give a sense of light—a Monet feeling. I work closely with the electricians, who have to follow my color scheme when doing the lighting."

Kalmenoff has painted many of the backgrounds and scenes in the hall, including Samarkand, Jerusalem after a thunderstorm, the Great Wall of China, the palace of the Dalai Lama reflected in a mountain lake, Jericho in about 6500 B.C., Troy and the Dardanelles, and the hanging gardens of Babylon.

"But my happiest painting," he says, "is Samarkand. Those rich, rich colors. You don't get any schooling for this kind of work. Most of the backgrounds are curved surfaces, and the color values and linear perspective

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours. You get reliable arrangements and expertly planned itineraries.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers...rain forests, mountains, and tundra...seashores, lakes, and swamps of the regions we visit. At the same time, we explore the more usual attractions in touring—the cities, archaeological sites, and people.

Where can you go with Questers? Virtually anywhere in the world. The current Directory of Worldwide Nature Tours describes 32 tours varying from 9 to 30 days. Following is a representative listing:

Worldwide Nature Tours
1981 Departures (Partial Listing)

The Americas
Everglades: 11 days, Mar. 26 & Nov. 5 • Hawaii: 15 days, Feb. 15, Apr. 12, July 12, Oct. 11 & Dec. 20 • Alaska: 17 days, June 6 & 20, July 4, 11 & 25 & Aug. 8 • Newfoundland: 16 days, June 14 • Baja California: 11 days, Apr. 17 & Oct. 16 • Costa Rica & Panama: 16 days, Feb. 14, Nov. 21 & Dec. 19 • The Amazon: 16 days, Jan. 19, May 11, July 6, Aug. 10, Oct. 12 & Nov. 16 • Peru: 23 days, Apr. 4, July 18 & Nov. 7 • Ecuador & Galapagos: 15 days, Feb. 5 & 26, Apr. 9, July 2, Aug. 13 & Oct. 15 • Trinidad & Tobago: 11 days, Mar. 9 & Nov. 9.

Europe
Iceland: 16 days, June 12, July 3 & Aug. 7 • Islands & Highlands of Scotland: 23 days, May 29, July 10 & Aug. 21 • Spain: 18 days, Apr. 17 & Sept. 4.

Asia and Africa
Indonesia: 24 days, July 14 & Sept. 8 • The Himalayas: 25 days, Mar. 19 & Oct. 8 • India: 21 days, Jan. 31 & Oct. 31 • Sri Lanka: 18 days, Feb. 19 & Nov. 19 • Kenya: 23 days, Feb. 5, July 23 & Oct. 22.

Oceania and Australasia
Australia & New Zealand: 30 days, Jan. 31 & Sept. 19 • New Zealand & the Milford Track: 22 days, Feb. 20 & Nov. 13.

change with the curvature. To make the paintings, especially their architectural details, look natural, is very difficult."

During our tour, we were struck by some of the more unusual aspects of the hall. Alex Williams departed from traditional Museum design in several respects, especially in the use of innovative lighting and modern painting styles. Williams commissioned Frank Mullins, the late artist who did covers for *Sports Illustrated*, to paint abstract and semiabstract backgrounds for several sections of the hall.

Most Museum-goers will find their first visit to the hall somewhat overwhelming. But it is hard to imagine how a Hall of Asian Peoples could accurately reflect its subject and not be overwhelming. Says Fairservis: "It would be wrong to give visitors the feeling that they had somehow 'seen' all of Asia, and it would be arrogant to say the hall 'encompasses' Asia. I believe, however, that the hall does give a fair statement of Asian values."

We asked Fairservis what he hoped to accomplish with the hall, what his goal was.

"The key to the whole hall," he replied, "lies in what it does to inform. There is in the West a real ignorance of Asia. If we look at our Asian foreign policy over the last forty years, we see a history of ignorance and inertia. We won't admit there are concepts

The Museum is planning a number of events in conjunction with the opening of the Gardner D. Stout Hall of Asian Peoples. Listed below are some of the special Asian programs planned for the fall. Look for more information on future programs in the "At the American Museum" column of *Natural History*.

**Fujian Hand Puppets from the People's Republic of China**

On tour for the first time in North America, a troupe of eleven puppeteers from the province of Fujian, China, will present four performances of the traditional Fujian hand-puppet theater. The troupe performs plays based on classical Chinese literature, and its members manipulate the foot-tall puppets with surprising agility. The puppets, carved in wood and dressed in richly brocaded costumes, smoke pipes, drink tea, fly through the air, and even spin plates on their heads. The Fujian puppets, presented through the Asia Society's Performing Arts Program, will be in the Museum Auditorium on Thursday and Friday, September 4 and 5, at 7:30 P.M., and Saturday and Sunday, September 6 and 7, at 2:00 P.M. Tickets may be purchased at the door, for $12.50 ($7.50 for members). Call 873-1327 for ticket availability.

**Civilizations of Asia**

Walter Fairservis, Jr., scientific consultant and curator for the Gardner D. Stout Hall of Asian Peoples, will give an evening lecture series entitled *Asian Civilizations*. In four slide-illustrated lectures, Fairservis will survey the major traditional cultures of Asia, from China to the Near East, focusing on religion, family life, language, and history. *Asian Civilizations*, which begins October 23, will run for four Thursday evenings, from 7:30 to 9:00 P.M. Series tickets are $20. For other offerings in the Evening Lecture Series, refer to the "At the American Museum" column in this issue.

**Ravi Shankar**

The well-known Indian sitarist and composer Ravi Shankar will give a lecture-demonstration of Indian music on Wednesday, September 10, at 7:00 P.M. in the Auditorium. He will play and discuss his music, and answer questions from the audience. Tickets are $6 ($5 for members) and may be purchased at the Auditorium door. Call 873-7507 for ticket availability.

**Films on Asia**

On four weekends in October and November, a series of free films on Asia will be shown in the Auditorium from 2:00 to 4:00 P.M. Each weekend will feature a different culture: October 18 and 19, India; October 25 and 26, Japan; November 8 and 9, the Himalayas; and November 15 and 16, China. Films include John Nathan's *Farm Song*, about the life of a rural Japanese family; a 1935 film by C.S. Cutting, *Beyond the Forbidden Frontier*, the earliest footage of life in Tibet; and three 1980 films on life in the People's Republic of China. For a complete schedule of films, write to the Education Department.

**Theater of the Deaf**

In December, the Education Department and the Touchstone Center will present *The National Theater of the Deaf*. Four deaf actors and one hearing actor will present a theater piece based on the life of Issa, the Japanese haiku poet. This free program is especially suited for young people. Look for more details in the December issue of *Natural History*.

and suppositions about the world other than our own. I feel a certain basic anger."

In the afterword to a book Fairservis is writing about Asia (excerpted in this issue), we find a passage that seems particularly appropriate to the new hall:

> Perhaps we of the West in the end will see and learn there were other ways of life not so long ago—indeed some still struggle to survive—and that these other ways were and are as valid as our own. Perhaps then in the perspective of Asian accomplishment we might find presuppositions other than our own materialistic ones and realize other courses to human happiness.

*Douglas J. Preston*

**Asian Arts**

The People Center will offer seven weekends of programs on Asia, starting October 18 and 19. The free programs, which run continuously from 1:00 to 4:30 P.M., will feature the traditional arts, crafts, music, and dance of India, Japan, China, Buddhist High Asia, Korea, and the Near East.

**Margaret Mead Film Festival**

The 1980 Margaret Mead Film Festival is also featuring several programs on Asia, including films and commentary on Iran and premières of several films on China. Look for details in the "At the American Museum" column of this issue. For a program of films write to the Department of Education.

**Gallery Talks**

Museum visitors are invited to attend several free one-hour gallery talks on the Hall of Asian Peoples. Participants will tour the hall with Museum instructors and learn about the great civilizations of Asia. *Introducing the Gardner D. Stout Hall of Asian Peoples* will be given on November 6 and 18 and December 4 and 16; *The World of Islam* on December 9; and *Asian Textiles* on December 30. All gallery talks start at the first floor Information Desk at 2:00 P.M.

**Holy Land Before Christ**

Claireve Grandjouan, professor of classics at Hunter College, will give a slide-illustrated lecture entitled *The Holy Land before Christ* in the Auditorium on Wednesday, December 3, at 7:00 P.M. Grandjouan will discuss how recent archeological finds shed new light on the history of the Holy Land. Tickets are $4.00 ($3.00 for members) and are available through the Education Department.

# Plants of Prey

### by Stephen K-M. Tim

CARNIVOROUS PLANTS, by Adrian Slack. *The MIT Press, $19.95; 240 pp., illus.*

Lush greenery in botanic garden conservatories always seems to evoke the same inquiry: Where are the man-eaters? Fertile minds once wrote of hand-picked maidens being sacrificed to fanciful plant life in the jungles of way-beyond. These vivid tales live on and continue to coax the imagination of modern man. However, there is little excuse for ignorance about carnivorous plants these days. Illustrated articles in popular magazines and highly refined cinematography have enabled our appreciation of these plants, which derive nutriment from the breakdown of insect bodies, to transcend the sensational.

The past decade has seen a phenomenal surge in the popularity of carnivorous plants. *The Carnivorous Plant Newsletter*, born out of the dearth of reliable information about growth requirements and availability, came into being in the United States in 1972. Its goal was the dissemination of interesting yet scientifically correct information. It was only logical that books would follow and this was precisely the case. These appeared from a number of countries, including Japan, the United States, and Australia. *Carnivorous Plants*, which made its debut in Great Britain in 1979, has now been made available through the MIT Press. The author is landscape architect and plantsman Adrian Slack, who has been captivated by these plants since childhood, but a number of American specialists assisted in the book's compilation.

The volume covers the world's genera of carnivorous flowering plants, emphasizing the most distinctive and better-known species. Descriptions have been kept as nontechnical as possible and a brief glossary clarifies unavoidable terminology. Since the traps of these plants are among the most specialized structures in the plant world, descriptions dwell on these to a large extent. Coverage bears upon the action of the trapping procedure and follows the system adopted by F.E. Lloyd in his book, *The Carnivorous Plants* (1942). Plants with passive traps are distinguished from those with active traps, which display some movement in the entrapment process. The avoidance of description by family makes the book less clinical. The author has not neglected the decorative aspect of these plants; the abundant and colorful flowers of the butterworts are a surprise when compared with those of the pitcher plants, whose bizarre flowers and complex pollinating mechanism seem suited to such unique plants.

The pitcher-type trap, a highly modified leaf, figures most prominently in the passive forms. Through a series of drawings, Slack presents a hypothesis for the origin of the funnel-shaped, pitcher-type structure. Such a trap is an ideal reservoir for water, and some species have evolved a variety of overarching hoods, or flaps, which serve to attract prey or act as an umbrella, preventing rainwater from diluting the fluid in the digesting chamber or washing out the prey. Elaborate mechanisms to lure insects into the "recesses of unlikely return" have appeared in different

## The cordless phone that works like a regular phone up to 300 feet from your house. Use it in your own back yard with our compliments. Keep it, if you wish, for ONLY $119.95!

I live on five acres. And I keep four horses in my back yard. Used to be, if I got a call while I was down at the corral, one of the kids would yell out the kitchen window and I'd do the hundred-yard dash to the nearest house phone.

No more. With The Phone Ranger I can groom Laird, my Palomino gelding, with one hand and call my broker with the other.

### Take or make calls up to 300 feet away.

Maybe you don't keep horses. But if you've got a pool, patio, garden, workshop, tennis court or garage—and you'd like the phone to come to you instead of you going to it—this is the answer.

Try The Phone Ranger for 15 days. Send it back if you want. If you decide to keep it, the best news is the price!

### Units that look like toys sell for up to $495.00!

There's a unit called "ROVAPRO" that looks like my son's toy walkie-talkie—not like a real phone at all—and it goes for a cool $495.00.

Then there's "MURAPHONE." It's $149.95. But it's even more like a toy walkie-talkie. You have to push a button to talk and release to listen—with all that "Roger, over to you" stuff in between. Not like a real phone at all.

The Phone Ranger looks like a real phone, rings like a real phone, dials out like a real phone . . . has a range of 300 feet . . . and it's only **$119.95** plus $5.95 shipping and handling. If you'd prefer a range of a full 750 feet, order the deluxe version for only $189.95 plus $5.95 shipping and handling.

### Doubles as an extra extension phone.

When you're not using it outside, use it as an extra extension phone without paying monthly charges to the phone company.

### Works so simply.

Plug base unit into phone jack and into AC house current. Then plug The Phone Ranger into base unit to charge battery. Now unplug The Phone Ranger and you're ready to use it to take or make calls up to 300 feet away (750 feet if you choose the deluxe version). Red indicator light tells you when it's time to recharge.

If you don't have a phone jack, the phone company will install one for a nominal one-time charge. If you have an old-fashioned, 4-prong jack, The Phone Ranger comes with an adaptor you can use. Even if you live in an area with rotary dialing, the pushbutton system on your Phone Ranger will work. And the entire unit is FCC approved.

### Includes amazing "last number" memory!

No need to re-dial when you get a busy signal. Just press the # or the * button and The Phone Ranger automatically redials the last number you called!

(A great security idea: "program" your phone to your local police number before you go to bed. The touch of a single button alerts police in case of emergency.)

Pick up your regular phone right now. Here's the number to call . . .

**CALL TOLL-FREE**
**800-621-5839**

(In Illinois, call 800-972-5858)

For faster service, give this number 15-5000 as soon as the operator answers. Lines are open 24 hours, 7 days a week.

If you're using your credit card, use our toll-free number. If you prefer, send your check to Roy Thomas & Associates, Inc. at the address below. (Illinois residents add 6% sales tax.)

You must be completely satisfied with The Phone Ranger. If for any reason you're not, return it within 15 days for a full refund, no questions asked. Use the carton it comes in to return it.

I know you'll have fun with it. Order now.

Jana Gata

*Drosera binata*

ways. Insects, enticed to explore the open rim by a "bait" of nectar secreted by strategically positioned glands, often plummet into the watery depths. The tropical pitcher plant, *Nepenthes*, for instance, has loose, waxy secretions, just below the inside rim of the pitchers, that clog the footpads of normally sure-footed ants. Little wonder these traps are often filled with the empty bodies of these insects.

Further action in the pitchers follows one or a combination of two processes. In the case of the sun pitcher, *Heliamphora*, and the cobra lily, *Darlingtonia*, bacterial action within the watery medium is solely responsible for the breakdown of the soft parts of the insect. In contrast, in the trumpet pitcher, *Sarracenia*; the tropical pitcher plant, *Nepenthes*; and the West Australian pitcher plant, *Cephalotus*, the fluid first becomes acidified, enabling a protein-digesting enzyme, similar to that found in the human stomach, to act on the prey's softer tissues. The nutritive fractions are then assimilated through the walls of the pitchers.

Three other genera are covered in the passive section. Of these, *Genlisea*, the least well known, is not widely cultivated at present. This is surprising, considering the wide distribution of the species. The other two, *Byblis* and *Drosophyllum*, are both equipped with abundant, shimmering mucilaginous glands on their narrow, tapering leaves. The sticky fluid will smother struggling insects and digestive enzymes do the rest. *Drosophyllum*, the Portuguese sundew, is atypical among the carnivorous plants; it inhabits dry, often alkaline rocky outcrops in Spain, Portugal, and Morocco, whereas almost all other carnivorous plants are confined to acidic environments in freshwater bogs or other wet to moist situations.

Slack was unconventional in not describing the species with active traps first. Whatever the reason, if indeed any was contemplated, his approach does force the reader to get away from the common association of carnivory in plants with movement, particularly that encountered in the popular Venus flytrap.

In an overall survey of the plants in the active section, only two families are found, the Lentibulariaceae (bladderworts and butterworts) and the Droseraceae (sundews). Yet, so varied are the members in each family that one might be tempted, at first glance, to consider them unrelated. Although they are in the same family the butterwort, *Pinguicula*, and the bladderwort, *Utricularia*, differ greatly in form. Minute, sticky glands cover the rosette of broad leaves in *Pinguicula* and smother very tiny insects. A slight inrolling of the leaf margins justifies the placement of *Pinguicula* among the active traps. In contrast, *Utricularia* is endowed with numerous, highly complex, and sophisticated traps in the form of tiny submerged bladders. Each bladder is under negative pressure internally until a small insect, usually a water flea or nematode, stimulates the sensitive trigger hairs around the periphery of its inwardly opening door. This causes the one-way door to suddenly swing open, and the resultant inrush of water sweeps in and traps the unsuspecting prey. Digestion in both the butterworts and bladderworts is by enzymes.

Jana Gata

*Sarracenia leucophylla*

In the sundew family, equally striking distinctions among the members are obvious. The well-known Venus flytrap, *Dionaea*, with its two-lobed trap and spinous outgrowths that interlock when the trap is sprung, needs little introduction. It remains one of the most spectacular of carnivorous plants that "perform" at the macroscopic level. In contrast, the sundew, *Drosera*, has numerous, sticky, gland-tipped tentacles covering mainly the leaves; these tentacles and most of the leaf itself curve over the prey, making full contact with it. Glands, in both cases, secrete enzymes. The characteristics of *Drosophyllum*, a member of this family covered earlier in the passive section, further emphasize the variety within this one family. Two other genera, *Aldrovanda* and *Polypompholyx*, are also included among the active members.

A striking feature of the book is the black-and-white and full-color photographs, the product of the highly skilled artist Jane Gate. The dramatic portraits complement the text in a thoroughly meaningful way. I was especially impressed with one black-and-white photograph of *Sarracenia minor*; the two hooded traps, with a pair of ants feeding on bands of nectar around the open lips, illustrate an unusual food chain—the impending demise of the ants, themselves drinking in the nectar, and the resultant enrichment of the plants. My only criticism here concerns the lack of habitat studies; the environs of carnivorous plants are often as specialized as the diverse plants they spawn.

The culture of these plants is confined to a separate section. Temperature, light, and humidity requirements are clearly outlined and growing media for each species are recommended. Propagation is also covered in depth. May I offer a few points of clarification here. When artificial light is used for growing, the daylight tube alone provides an insufficient spectral range and should be combined with, at least, a warm white tube. Slack does advocate combining the daylight tube with one of the fluorescent plant-growth lights as an alternative. Secondly, I would like to underscore the

*For the fourth year, we invite adventurous travelers to join us on a unique travel experience*

The Snows of Kilimanjaro

FEBRUARY 6 TO 23, 1981

Our expedition begins with a tented wildlife safari in Tanzania's Tarangire National Park, Ngorongoro Crater, the Serengeti Plains and Lake Manyara, where we undertake hikes to prepare us for the ascent of Africa's highest mountain, crowned with its permanent icecap.

In order to make the climb not only memorable but enjoyable, we allow plenty of time for resting at huts and camps to become used to the high altitude.

*Detailed brochures of this expedition and a copy of our newsletter which lists all our fascinating travel programs, available from:*

HANNS EBENSTEN TRAVEL, INC
705 WASHINGTON STREET, NEW YORK, NY 10014
TELEPHONE (212) 691 7429

author's reservations about precluding ventilation in greenhouses in warm climates so as to maintain a high humidity. In such cases, ventilation and the use of fans to encourage air circulation are essential to reduce the incidence of plant disease. Finally the fumigant BHC, recommended for plant pests on *Drosera*, is banned in the United States and an alternative insecticide must be used.

Unfortunately, of the many errors scattered throughout this quality publication, a number were not picked up in the book's listing of errata; these range from spelling errors to taxonomic misrepresentation. As an example of the latter, the use of single quotation marks with *Drosera* 'Bannister' indicates a registered cultivar name. However, this is an acknowledged temporary name until the plant (it is said to be a new species) is validly described. Until then, double quotation marks should have been used, hence: *Drosera* "Bannister." Lastly, a small point: There was a tendency toward anthropomorphism in descriptions involving the capture of prey but I must admit that this is my own personal aversion, particularly where carnivorous plants are concerned.

In our present world, specialized specialists are becoming the order of the day. Once there were gardeners; now there are specialist gardeners. In the study of the carnivorous plants there are already many "one genus" specialists, so a book that covers the subject widely—and attractively—is a most refreshing and welcome reference tool that will fill many gaps in the available literature.

Today the future of many carnivorous plants is in jeopardy; their numbers diminish as their often fragile habitats are plowed under and developed. Commercial exploitation of wild species and, sadly, the removal of these plants by unthinking hobbyists are equally to blame. Perhaps the influence of books, such as this one by Adrian Slack, which not only informs so invitingly but also stresses reserve where collecting is concerned, will encourage conservation through education.

*Stephen K-M. Tim is taxonomist at the Brooklyn Botanic Garden where, in 1974, he assembled a collection of carnivorous plants for display. He lectured in botany at Rhodes University in South Africa before coming to the United States.*

AFRICAN ELEPHANT IN FINE PEWTER

A SPECIAL COLLECTORS' EDITION FROM THE GALLERY!

Don Polland's famous sculpture captures the moment of stampeding rage . . . all the strength, fury and brute grace of this maddened elephant. 7"h, 6"w, 8½"l on a solid Honduras Mahogany wood base. Signed and numbered. Send check or M.O. Or credit cards. Give Acct. No., Guaranteed.

# The 1980 Margaret Mead Film Festival

When films . . . are functioning at their best, the people in them seem bearers of the immeasurable wealth and effort of human experience.

David MacDougall, *Principles of Visual Anthropology*

The late Margaret Mead's concept for the first Margaret Mead Film Festival in 1977 was to bring the rich variety of human experience to a general audience through one of her favorite anthropological tools—the camera. Faithful to Mead's ideal, the 1980 Margaret Mead Film Festival will again enable interested people to meet filmmakers and anthropologists and take part in discussions of their work.

This year the festival honors the filmmaking team of David and Judith MacDougall. Graduates of the UCLA Film School, the MacDougalls have made nearly a dozen films in Africa, Australia, and the United States. They will show and discuss four of their recent films on Wednesday and Thursday evening, October 1 and 2.

In 1973/74 the MacDougalls spent fourteen months with the Turkana of East Africa: eleven months getting to know them and three months filming. They often spent twelve hours or more per day with their subjects, their camera always in filming position. David MacDougall says, "I lived looking through the viewfinder. But because the camera ran noiselessly, my subjects soon gave up trying to decide when I was filming." The Turkana finally resumed the normal course of their lives, allowing the filmmakers to record intimate scenes "without embarrassment or pretense on the part of the subjects."

The MacDougalls plan a trilogy of films from the 35,000 feet of film they shot in Africa. The second and latest in the series is *Lorang's Way*, which will be shown on Wednesday evening, October 1. Through conversations with Lorang and glimpses of him with friends and family, the MacDougalls show us a dignified, complex man who views his society as vulnerable and whose traditional role has been reshaped by that realization. *Under the Men's Tree*, a second, much shorter film that the MacDougalls made on an earlier trip to Africa, will also be shown. This film records an interesting case of "reverse ethnology" as a group of Jie cattle herders in Uganda discuss the industrialized world's great status symbol, the automobile. Laughing among themselves, they go over the qualities of cars and the relative worth of cars and men.

In 1975, David was appointed director of the film unit of the Australian Institute of Aboriginal Affairs,

*Workers in a commune from* North China Commune *(première October 4, Auditorium)*

National Film Board of Canada

*Hortense and Christina Miller appear in* Quilts in Women's Lives *(October 5, Gallery 3)*

Debra Heimerdinger

**Signs or Sentences?**

Herbert Terrace, who raised the famed chimpanzee Nim Chimpsky and tried to teach him sign language, will give a free slide lecture entitled *The Grammatical Capacity of Apes* on Wednesday, September 24, at 7:30 P.M. in the Auditorium. This program is presented in cooperation with The New York Academy of Sciences.

**Evening Lecture Series**

For those interested in anthropology, natural history, geology, and botany, the "Adult Evening Lecture Series" is an excellent opportunity to broaden your knowledge. Series topics this fall include *Asian Civilizations*, taught by Walter Fairservis, Jr., scientific consultant for the Museum's new Gardner D. Stout Hall of Asian Peoples; *Archeology Today*, taught by David Hurst Thomas, chairman of the Department of Anthropology; and numerous other subjects, from sociobiology and animal behavior to wildlife drawing and mineral identification. Write to the Department of Education for a course brochure.

**Courses for Stargazers**

The Hayden Planetarium is offering a large selection of courses in astronomy, navigation, and aviation for both adults and children. The Planetarium is also planning *Cosmos*, a special twelve-week course based on the television series written and presented by Carl Sagan. *Cosmos* will be taught by Lloyd Motz, professor of astronomy at Columbia University, and will explore numerous scientific topics from a humanistic perspective. The course will take up such subjects as the theory of relativity and the creation and evolution of the universe. A catalog and application may be obtained by writing to the Hayden Planetarium.

**The End of the World**

*The Planetarium All-Stars Show* opens Monday, September 8, at the Hayden Planetarium. This live sky show presents the current sky, its constellations, the motions of its planets, and other astronomical events. On September 25, *The End of the World* opens. Sometime in the future the world must end. How it will end—whether by the death of the sun, collision with a comet or asteroid, the coming of a new ice age, or nuclear Armageddon—is open to debate. *The End of the World* takes a dramatic look at present-day theories.

**Workshops for Young People**

The Education Department has again prepared a series of *Workshops for Young People*. The courses are designed to give hands-on experience with science to children in grades 4 through 7. Five workshops—covering topics in anthropology, natural history, and animal behavior—will be offered. Contact the Education Department for a course brochure and application.

**Discovery Tours**

The Museum is offering a tour of the Galápagos Islands and the highlands of Ecuador in June 1981. John Bull, a Museum ornithologist, and Charles Cole, a Museum herpetologist, will lecture on the diverse and unusual species of birds and reptiles found in these areas. For further information about the 1981 Museum travel program, write to Discovery Tours.

and Judith, film assistant. Two films that resulted from the MacDougalls' work with the aborigines of Aurukun, Queensland, are *The House Opening* and *Familiar Places*. These films, which will be shown on Thursday, October 2, look at different aspects of the aborigines' adaptation to, and conflict with, European ways.

In addition to presenting their views on filmmaking and various theories of ethnographic film, the MacDougalls will discuss working together as a husband-wife filmmaking team.

Series tickets for the two evenings with David and Judith MacDougall are $10 ($8 for Museum members) and may be purchased in advance from the Education Department.

On the weekend of October 4 and 5, the free films and discussions will cover an eclectic range of topics—from Chinese communes to the black experience. Many anthropologists and filmmakers, including Jean Rouch, Ray Birdwhistell, Alan Lomax, and Catherine Bateson, will be on hand to introduce and discuss the films.

One of the festival's major programs will première four films on the People's Republic of China. Shortly after the United States and China normalized diplomatic relations, an American film crew was given permission to interview and film in areas previously closed to the West. On Sunday, October 5, these three filmmakers, Sue Yung Li, Shirley Sun, and Peter Wang, will screen and discuss their films, *Suzhou* and *Beijing*. *Suzhou*, set in the traditional environment of canals, gardens, and silkworm farms, explores the city, its people, and their values. *Beijing* looks at the former imperial capital, and through interviews and scenes of daily life, shows how the political, social, economic, and cultural changes of this century have influenced the lives of the people. The filmmakers interviewed, among others, Pu Jieh, the brother of the last emperor of China, who reminisces about his youth in the imperial court and compares it with his present role as a representative in the People's Congress.

On Saturday, October 4, *North China Commune* and *North China Factory*, made under the aegis of the National Film Board of Canada, will be introduced by the filmmakers, Tony Ianzelo and Boyce Richardson.

Another major program, *Perspectives on Iran*, features two Iranian films never before shown in the United States. Anthropologist Catherine Bateson, Margaret Mead's daughter; William Beeman, an anthropologist who lived in Iran throughout the recent revolution; and Bahman Maghsoudlou, an Iranian filmmaker, will discuss these films and what they can teach us about Iranian culture.

Although this year's festival includes a number of classic ethnographic films, its emphasis is on new films. One film that caused a sensation in Australia when it was released last year was *The Last Tasmanian.* The Tasmanian aborigines, who had lived in the same area for at least 23,000 years, were wiped out in less than 75 years by disease and genocide. The film traces the fifteen-year search of anthropologist Rhys Jones, who pieced together a picture of the last Tasmanians—their culture, technology, artifacts, and swift extinction.

Other programs making up the 1980 Film Festival are *Recent Landmarks*, *Film for Research and Teaching*, *Dance-Drama in Java and Thailand*, *Soviet Ballet*, *Latin American Faith and Ritual*, *Dogon Funeral Ceremony*, and *Black Experience*.

Programs will be distributed at the Museum's entrances before and during the festival.

# EVENING LECTURE SERIES

## American Museum of Natural History

## Beginning October, 1980

**ASIAN CIVILIZATIONS**—4 Thursdays starting October 23, 7:30-9:00 p.m.
Fee: $20.00

**Dr. Walter A. Fairservis, Jr.,** Professor of Anthropology at Vassar College and Research Associate in the Museum's Department of Anthropology, uses color slides to survey several major cultures of Asia, from China and Indo-Pakistan to the Near East. Religious systems, family life and history are examined in the context of intercultural influences. This series coincides with the opening of the Museum's Gardner D. Stout Hall of Asian Peoples, for which Dr. Fairservis was scientific advisor.

**ARCHAEOLOGY TODAY**—4 Mondays starting October 20, 7:30-9:00 p.m.
Fee: $20.00

Archaeology has undergone a technological and a theoretical revolution in the past decade. In illustrated lectures, **Dr. David Hurst Thomas**, Associate Curator and Chairman of the Museum's Department of Anthropology, explores several of these breakthroughs. "Classic" and contemporary expeditions are used to provide a broad overview of the questions asked by archaeologists and how they provide answers.

**GEOLOGY OF NEW YORK**—4 Tuesdays starting October 21, 7:00-8:30 p.m.
Fee: $20.00

This slide-illustrated series explores the geological history of New York. **Sidney Horenstein**, a staff member in the Museum's Department of Invertebrates, discusses New York's Foundation Rocks, Ice Age New York, Landscapes and Ecology, and Building Stones—New York's other Geology.

**SOCIOBIOLOGY**—6 Tuesdays starting October 21, 7:00-8:30 p.m.
Fee: $35.00

**Dr. Ethel Tobach**, Museum Curator of Animal Behavior, examines arguments for and against the theory of sociobiology as an explanation for the human condition. Using some of the Museum's exhibits as well as live animal demonstrations, Dr. Tobach will explore the implications of these controversial questions.

**WILD FLOWERS OF THE NORTH**—6 Thursdays starting October 23, 7:00-8:30 p.m.
Fee: $30.00

**Helmut Schiller**, Lecturer in Botany at the Museum, explores with slides the world of wild flowers of northern mountains, coniferous forests, and wetlands, from Alaska and the Pacific Northwest to New England.

**EXPLORING AMERICAN WILDERNESS AREAS**—6 Thursdays starting October 23, 7:00-8:30 p.m.
Fee: $30.00

Much of the remaining scenic grandeur and wildlife of the United States and Canada is restricted to federally preserved areas such as National Parks, Monuments and Wildlife Refuges. Using rich color slides, **Kenneth A. Chambers**, Lecturer in Zoology at the Museum, introduces some of the most beautiful of these regions.

**CENTRAL PARK: NEW YORK'S REMARKABLE BACK YARD**—4 Mondays starting October 20, 7:00-8:30 p.m.
Fee: $20.00
Author **Elizabeth Barlow**, Administrator of Central Park, takes you on a slide tour of Central Park's history and natural history.

### Register Now!

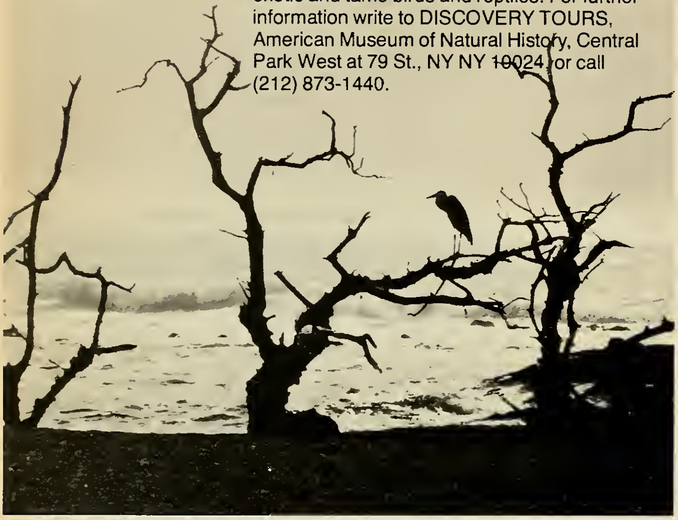
GALAPAGOS ISLANDS CRUISE
June 13 to 25, 1981

Share the educational holiday of a lifetime with American Museum scholars and 65 compatible travelers aboard the comfortable M.V. Buccaneer. Enjoy superb climate and sandy beaches, while exploring volcanic landscapes, home to exotic and tame birds and reptiles. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.



Whole Wheel of Very Sharp Cheddar ½ Price
*until Nov. 25, 1980*

As part of a marketing test in cooperation with the largest cheese organization of its kind in North America, we have agreed to ship from our maturing vaults to the address of any Natural History Magazine reader responding to this notice before Midnight Nov. 25, an entire 2-lb. wheel of virgin uncut (very) sharp farm Cheddar, regularly $15.00, for the sum of $7.50 plus $2 for transport & handling. There is no further monetary requirement. Should you wish to return any remaining portion of your Cheddar wheel after tasting (no matter how small this remaining portion may be) you may do so without question to the address below and receive a full refund. Your request for a half-price Cheddar wheel must be made before Midnight Nov. 25, or it will not be accepted and your uncashed check will be returned. There is a limit of one (1) wheel per address, but if your request is postmarked before Nov. 10, you may request a second wheel by enclosing an additional $7.50 plus $2 for transport & handling. Send to: **Cheeselovers International, Dept. 569-6, 1200 Shames Drive, Westbury, New York 11590.** Or you may charge it to your **VISA** or **Master Charge** card by phoning **800-228-2021.** (In Nebraska, phone **800-645-3197.**) The call is toll-free and our phones are open 24 hours a day.

# Far-out Erupting Volcanoes

*How a discovery about Io, one of Jupiter's moons, was made*

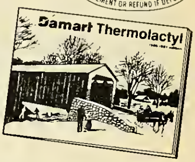
**by Stephen P. Maran**

Of all the fantastic phenomena observed by the immensely successful *Voyager* mission to the planet Jupiter, none excites the imagination more than the discovery of erupting volcanoes on the Jovian moon Io (see "By Jove," *Natural History,* May 1980). Indeed, this finding so intrigued various magazine editors that last January, the same *Voyager* photograph of a volcanic eruption was run on the covers of *Smithsonian, National Geographic,* and *Scientific American.*

Although there is evidence of past volcanic processes on our moon and on the planet Mercury, and giant volcanic mountains have been photographed on Mars and have been inferred, by means of cloud-penetrating radar, to exist on Venus, volcanism is most likely dead on all of those objects. Even if this judgment is found to be premature—like the opinions of those Washington State residents who thought Mount St. Helens was permanently dormant—the fact remains that, before the *Voyager* mission, erupting volcanoes had been seen only on the earth. Before *Voyager,* we also had no direct evidence of the processes at work in the interiors of celestial bodies beyond our moon. Now the *Voyager* photos and instrumental readings tell us about the tiny world of Io, suggesting the presence there of deep deposits of molten material, perhaps sulfur and its compounds, or earthlike magma impregnated with an unusual amount of sulfur.

The official report of the discovery of Io's eruptions, a three-paragraph paper in *Science* magazine, was signed simply "L.A. Morabito, S.P. Synnott, P.N. Kupferman, and Stewart A. Collins." With the exception of Collins, the authors were not members of the NASA imaging team, the scientific group selected for research with the *Voyager* cameras. They were, instead, members of the support staff at the Jet Propulsion Laboratory (JPL) in Pasadena, assigned to the extensive preparatory work of the space mission. Thousands of engineers and scientists like them make up the behind-the-scenes staff of the space program, people who do the lion's share of work needed to ensure that all will go well at the moment of truth when the spacecraft encounters another world.

Linda Morabito, who spotted the first eruption on Io while working as an engineer with the *Voyager* Navigation Team, is credited with developing computer programs to analyze star positions and keep track of the spacecraft trajectory. Steve Synnott, of the same team, helped develop ways to process images and analyze orbits. Stewart "Andy" Collins is a supervisor in the photo-science group, the technical staff for optical and photographic matters. And Peter Kupferman, also a member of the latter group, was its liaison representative



Chilled to the Bone!

Wherever the winters are cold, with temperatures in the "teens" and "wind-chill factors" even lower, people are talking about Damart Underwear.

And no wonder! Damart is the unique underwear that keeps you amazingly warm, dry and comfortable no matter how cold it gets, no matter how hard the wind blows. No matter how long you stay out! You'll have to run your fingers over Damart Thermolactyl to discover how soft it is! You'll be thrilled at Damart's light weight that lets you move so easily.

Damart does this with a new miracle fabric—Thermolactyl. It's knitted to let *perspiration out!* No other underwear does this! You can wear Damart indoors too, and turn your thermostat into the 60's. You'll feel perfectly comfortable and enjoy dramatic savings in home heating costs.

Damart is so comfortable that the Mt. Everest climbing expedition wears it. So does the Chicago Bears Football Club, New England Patriots and Philadelphia Eagles.

Our free catalog tells the full Damart Thermolactyl story and displays the whole Damart line for men, women and children *including tall sizes.* Send for your FREE copy now!

to the Navigation Team. He computed the exposure times for the *Voyager* photographs and helped calibrate the cameras. With the exception of Collins, the four authors could hardly have anticipated that one day they would publish their own major discovery made with *Voyager.*

Any two eyewitnesses to history, like any two witnesses to an automobile accident or a bank robbery, will tell slightly different stories. The following account, based primarily on Kupferman's recollections as told to me many months after the fact, is a subjective impression of how events unfolded and how the discovery of Io's eruptions was confirmed.

Like the mariners of old, the *Voyager* navigators use the positions of stars as seen from their "ship," in this case a spacecraft, to determine where they are and how fast they are going. These stars—in the instance of *Voyager*—are 8th or 9th magnitude in brightness, too faint to be seen with the naked eye but observable with the spacecraft cameras. Photographs properly exposed to gain information about Jupiter and its moons are referred to as "science frames." Pictures taken with the same cameras but using longer exposures in order to feature background stars beyond the planet are called "navigation frames."

A one-second exposure shows the 8th magnitude stars quite well but leaves the fainter 9th magnitude stars rather weakly imaged. However, longer exposures cause the star images to trail into short arcs because the spacecraft moves during the interval of the exposure. Blurring is absent in the beautiful science frames of Jupiter and its moons sent back by *Voyager* because those objects are so bright that the exposure times are generally less than one second.

Navigation frames were generally taken at large distances from the Jupiter moons system as *Voyager 1* approached its March 5, 1979, rendezvous with the giant planet and, later, as it proceeded toward Saturn. Prime flyby time—when the spacecraft was nearest Jupiter and its moons and when the moons thus appeared largest through the camera lenses—was devoted to science frames. Thus, the science team generally ignored the navigation frames, which were presumed to be overexposed and to contain only small and therefore not sharply resolved images of the moons.

On the morning of Friday, March

**Lifelike Bird Carvings**

Bob and Bonnie Allen, Master Carvers of Chillicothe, Illinois produce accurate, lifesize reproductions of birds. This quizzical little chickadee is so lifelike it would be a delightful addition to any bird carving collection. $200.00 postpaid.

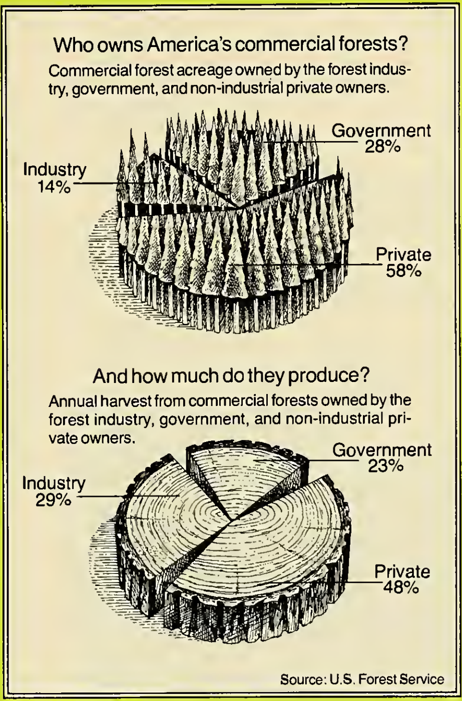
A report on the great American forest.

# Good forest management means growing more trees. Not sharing shortages.



Who owns America's commercial forests?

Commercial forest acreage owned by the forest industry, government, and non-industrial private owners.

And how much do they produce?

Annual harvest from commercial forests owned by the forest industry, government, and non-industrial private owners.

Source: U.S. Forest Service

It's no accident that the most productive forests in America are those owned and managed by the forest industry.

Although they make up only 14% of the commercial forestland, they provide 29% of the annual timber harvest.

This is because the industry has learned that it's not only possible to grow more trees faster, but also imperative.

It's a race against time: Every year Americans need more lumber and plywood to build homes. More furniture to make them liveable. More paper and pulp to print the books and periodicals that educate, enlighten and entertain. More packaging and containers for thousands of essentials, from milk to machinery.

The sobering fact is that within 50 years U.S. demand for wood and paper products is expected to double.

Yet not all the nation's commercial forests are working equally hard to get ready.

## What is a commercial forest?

*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland — whether owned by individuals, government or the forest industry — that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.

On all commercial forestland, tree growth per acre averages only 61% of potential, which is not good enough. The greatest room for improvement, however, is in National Forests, where trees now grow at only 48% of potential.

Yet as the industry has shown, the growth cycle can be speeded by applying such techniques as: encouraging natural regrowth, planting superior seeds and seedlings, fertilizing, thinning and protecting trees from disease, insects and fire.

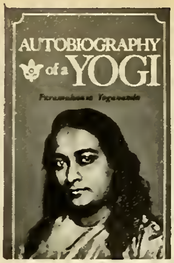
## How soon can we start growing more trees?

Since we clearly have the know-how to grow more and higher-quality trees, how soon can this nation get on with the job of increasing productivity on *all* commercial forestlands?

The first step is to understand the problem. If you'd like to learn more about the importance of America's forests and the challenges they face, send for a free booklet, "The Great American Forest." Write American Forest Institute, P.O. Box 873, Springfield, VA 22150.

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**



**Experiencing the Power of the Mind**

As modern researchers explore the workings of the human brain, one intriguing question continues to arise. We seldom use more than 10% of the brain's tremendous capacity—*what about the other 90%?*

Are there ways to tap this unused reservoir, to activate the latent intelligence of the human mind? Science and fiction alike testify to the efforts of many who, through experimentation or imagination, have sought to realize the mind's vast inner potential. AUTOBIOGRAPHY OF A YOGI is the fascinating account of one who succeeded.

Paramahansa Yogananda's lucid, and often entertaining, explanations of the subtle yet definite science of Yoga have established AUTOBIOGRAPHY OF A YOGI as a classic in its field; it is required reading in courses at over 100 universities.

"There has been nothing before, written in English or in any other European language, like this presentation of Yoga."

9, Morabito was examining the electronically displayed image of a navigation frame of Io and two stars. To "bring up" the weakly exposed image of the fainter star, she used a contrast-enhancement feature at her computer console. On the enhanced photograph, she discovered a thin crescent just outside the limb of Io. Io itself was a crescent moon in this frame, taken at a distance of 2,800,000 miles as *Voyager 1* looked back while proceeding toward Saturn. We now know that the small, thin crescent was a cloud of erupted solid particles and gas, seen from the side. No such ghostly arc had been observed before.

Kupferman got a message that morning to go see Morabito. Exhausted from helping the science team day and night during the Jupiter flyby and its immediate aftermath, he at first ignored the message. Later in the day, while a press conference on flyby results was under way, he headed for Morabito's office where she pointed out the arc on her screen. It showed on only one photograph. Was it real or an optical effect? Perhaps scattered light in the *Voyager* instrument or glare or some strange multiple reflection? If another Jovian moon were located behind Io as seen from *Voyager*, it too would have had a crescent appearance. Was this the explanation of the crescent? In fact, if Io itself had a moon, the subordinate moon also would have had an illuminated crescent shape in the reflected light of the sun. Morabito and Synnott checked on the other known Jovian moons but soon found that there was no chance that any of them had been in the background when the Io photograph was made.

Another remarkable feature on the screen, ignored at the time but later to attract much attention, was a bright spot on the dark part of Io, just inside (but not within) the solar-illuminated crescent of the moon itself.

After looking at Morabito's photograph, Kupferman got Collins, the photo-science supervisor, on the phone and told him with some urgency, "There's something you ought to see on one of the navigation frames." When Collins arrived, he took one look and said, "I bet you that's a volcanic eruption." The possibility may have been discussed earlier, and indeed a trio of scientists from the University of California, Santa Barbara, and the NASA-Ames Research Center actually had predicted active volcanism

*For the ninth year, we repeat our unusually interesting outdoor program led by a capable mountaineer:*

**Himalayan Trek in Nepal**

FEBRUARY AND NOVEMBER, 1981

These expeditions combine a trek on foot in the Annapurna region with a journey on elephant back through the Terai jungle, and a canoe trip on the Rapti River. Between the treks, first class hotel accommodations are provided; and the expedition ends with five days in Northern India, visiting Delhi, Agra and Jaipur.

*Detailed brochures of this expedition and a copy of our newsletter which lists all our fascinating travel programs, available from:*

on Io. But no one seriously expected to see an eruption in progress. Terrestrial volcanoes do not produce plumes two hundred miles high, as we now observe on Io.

We also now know that the temporarily ignored bright spot within Io's crescent was a second eruption emanating from a volcano on the dark part of Io. The plume extended up so high that it caught the rays of the sun like a high cloud overhead just after sunset. At the time, however, the navigators were concentrating on determining whether a volcanic eruption could truly account for Morabito's arc off the limb of Io. The fact remained that they had only one photograph of it. Based on the position of the arc off the limb, and assuming that it was right at the limb rather than well beyond it along the line of sight, Morabito and Kupferman estimated the location of the spot on Io beneath the arc. Would this location correspond to any interesting surface feature noted in the properly exposed science frames?

Kupferman had previously worked at a solar observatory and still had the program for his pocket computer that was used to relate sunspot positions on an observatory TV screen to solar latitudes and longitudes. This program was adapted to the problem at hand, and by the end of the day, the calculation was done. In another room at JPL, a cartographer was still at work, airbrushing details onto a new Mercator projection map of Io, based on the close-encounter science frames. The artist stepped back from her drawing board and the excited pair checked their computed coordinates against the map. One end of the arc was right over a heart-shaped surface feature on the map. Scientists earlier had speculated that this feature might be a volcano. Now the navigators knew that it must be even more than that—it was an *active* volcano.

At this point, although still dependent on the single navigation frame, the discovery seemed solid enough to report. Most of the science team had left town for a long weekend at home with their families in college towns around the country. The leaders of the team were reached by phone over the weekend and one member, Joseph Veverka of Cornell University, prepared to reexamine all of the science frames of Io with enhanced contrast.

By Monday morning, several of the scientists had gathered at the lab with Veverka when Kupferman strolled in at about nine o'clock. He remembers that as he entered he heard "cheers and amazed cries." Looking across at a TV screen, he saw a beautiful volcanic plume on one of the enhanced science frames. The navigators' discovery had been confirmed.

In all, eight erupting volcanoes were found on Io by *Voyager 1*. When *Voyager 2* came by Io eighteen weeks later, seven were still erupting. Some physicists now speculate that the eruptions are of such magnitude that the physical cause, assumed by the three scientists previously referred to who had predicted the volcanism, namely, tides raised inside Io by the powerful gravity of Jupiter, is insufficient to account for them. Instead, the physicists hypothesize that powerful electrical forces are at work, enhancing the heating of Io's interior and generating the molten stuff. Other *Voyager* findings show that some of the gas erupted from Io becomes electrified and streams down lines of magnetic force onto the polar regions of Jupiter, where it causes brilliant auroras.

*Stephen P. Maran is senior staff scientist in the Laboratory for Astronomy and Solar Physics at NASA's Goddard Space Flight Center in Greenbelt, Maryland.*

# Additional Reading

**Pygmy Chimpanzees** (p. 32)

D. Freeman's *The Great Apes* (New York: G.P. Putnam's Sons, 1979), a large, colorful summary of recent field studies for the nonspecialist, contains a short, illustrated account of pygmy chimpanzees. *The Apes,* by V. Reynolds (New York: E.P. Dutton, 1967), is a somewhat technical account of the history of research on living apes. J. MacKinnon's *The Ape Within Us* (New York: Holt, Rinehardt and Winston, 1978), a comprehensive account of the natural history and evolution of the living apes, serves as the basis for prediction about humankind. "Pygmy Chimpanzees" by A. and N. Badrian (*Oryx,* vol. 5, no. 13, pp. 463–68), reports the results of a six-month behavioral study of these animals, conducted intermittently during 1974–75 in an equatorial rain forest in Zaire, and urges establishment of a chimpanzee reserve in Lomako Forest. "A Pilot Study on the Ecology of Pygmy Chimpanzees," by T. Kano, in *The Great Apes,* edited by D.A. Hamburg and E.R. McGown (Menlo Park: The Benjamin-Cummings Publishing Co., 1979), is an extensive study of the pygmy chimpanzee in its natural habitat.

**Pack Rat Fossils** (p. 40)

T.R. Van Devender's "Holocene Woodlands in the Southwestern Deserts" (*Science,* October 14, 1977, pp. 189–92), an account of twenty-nine radiocarbon-dated pack rat middens, documents the existence of woodland

**Asia** (p. 46)

Both the Koran and the Torah are important source material for further reading in Islam and Judaism. The Koran, the holy book of Islam and the true word of God as revealed by the Prophet Mohammed, is the ultimate legal and religious authority for Muslims. A.J. Arberry's *Koran Interpreted* (New York: Macmillan Publishing Company, 1964) is a modern translation of the Koran known for its literary qualities and respected by Muslims for its accurate rendition of Koranic style. The Torah, or strictly speaking the Pentateuch, comprises the first five books of the Bible—Genesis, Exodus, Leviticus, Numbers, and Deuteronomy.

*Sources of Indian Tradition* (1958), *Sources of Japanese Tradition* (1958), and *Sources of Chinese Tradition* (1960), were published by Columbia University Press, New York. For readers interested in learning more about India, China, and Japan, these two-volume works, edited by W. T. DeBary, offer excerpts from literary, political, and sociological works from classic times to the present.

*East Esia: Tradition and Transformation* by J.K. Fairbanks, E.O. Reischauer, and A.M. Craig, (Boston: Houghton Mifflin, 1977), provides an introduction to the history and civilizations of China, Japan, Vietnam, and Korea. The first half of the book traces the origin and development of East Asia's society and civilizations; the second half discusses the impact of

communities in the southwestern United States 10,000 years ago and hypothesizes that climate was affected by melting continental glaciers. In "Development of Vegetation and Climate in the Southwestern United States" (*Science*, May 18, 1979, pp. 701–10), T.R. Van Devender and W.G. Spaulding analyze pack rat middens, describe vegetational changes, and draw some conclusions about United States desert climates during the past 22,000 years. More theories about climate in the past can be found in *Pleistocene Extinctions: The Search for a Cause,* edited by P.S. Martin and H.E. Wright, Jr. (New Haven: Yale University Press, 1968).

*Katharine D'Agosta*

Western culture and technology.

A description of people who live by ancient traditions but have had to adapt to modern civilization can be found in D. Cole's *Nomads of the Nomads: The Al Murrah Bedouin of the Empty Quarter* (Arlington Heights: AHM Publishing Corp., 1975).

*The Malays: A Cultural History*, by R. Winstedt (Boston: Routledge and Kegan Paul, Ltd., 1961), gives information on the history, art, and culture of India and of the Far East, and will be of particular interest to students of Islam.

An illustrated work by R.A. Stein, *Tibetan Civilizations*, translated by J.E. Driver (Stanford: Stanford University Press, 1972) is an introduction to Tibet, its people, religion, and culture.

# Do You Read Small Ads Like This?

As part of an advertising test we will send a pair of genuine diamond stud earrings to every reader of Natural History who reads and responds to this printed notice before Midnight, November 25, for the sum of $5 plus $1 shipping, handling and insurance. There is no further obligation. (Each diamond of the pair is a genuine .25 pt 10-facet round diamond and will be accompanied by our Certificate of Authenticity to that effect.) This advertising test is being placed simultaneously in other publications. If you see it in more than one publication, please let us know, as this information is helpful to us. Should you wish to return your earrings you may do so to the address below and receive a full refund. There is a limit of (1) pair of diamond earrings per address, but if your request is made before November 14, you may request a second pair by enclosing an additional $5 plus $1 shipping, handling and insurance. No request will be accepted past the dates noted above; your uncashed check will be returned if postmarked later than those dates. Please enclose this original notice with your request (photocopies will not be accepted). Send to: ABERNATHY & CLOSTHER, LTD., **Diamond Earring Advertising Test, Dept. 569-8, Box 1310, Westbury, N.Y. 11590.**

American Museum of Natural History
Discovery Tours

**ARCHEOLOGY TOUR TO MEXICO Jan. 12 to 30, 1981**
**TO MAYA MESOAMERICA Jan. 31 to Feb. 22, 1981**

Discover the ancient civilizations and archeology of pre-Columbian Central America with the American Museum's C. Bruce Hunter. Sites in the Mexican tour include Cuicuilco, El Tajin, Jalapa, Cholula, Teotihuacan, Tula, Oaxaca, Mitla, Monte Alban, Cuernavaca, Xochicalco and Taxco. The Maya tour visits Palenque, Edzna, Chichen Itza, Uxmal, Kabah, Sayil, Xlapak, Labna, Coba, Tulum, Tikal, Copan and Quirigua. Tours include colonial towns, museums and the finest accommodations, and are limited to 18 participants. C. Bruce Hunter is Lecturer in Archeology at the American Museum, and author of A Guide to Ancient Mexican Ruins and A Guide to Ancient Maya Ruins. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

# Celestial Events

by Thomas D. Nicholson

**The Moon** Watch for the harvest moon from September 23 to 25, and the hunter's moon on about the same dates in October. At both times the full, or nearly full, moon appears to fill the eastern sky with brilliance from sundown for three nights in succession. Moon phases in September are: last-quarter on the 1st, new moon on the 9th, first-quarter on the 17th, full on the 24th and last-quarter again on the 30th. The October new moon is on the 8th, first-quarter on the 16th, full moon on the 23rd, and last-quarter on the 30th.

**Stars and Planets** The bright planets are just about evenly divided between the evening and morning sky: two evening stars (Mercury and Mars), one morning star (Venus), and two planets (Jupiter and Saturn) shifting from the evening to the morning sky. But only one, Venus, can be readily seen. It puts on a very good show as a morning star, rising between 2:30 and 3:30 A.M. daylight time, high and brilliant in the southeast at dawn, and fading in late twilight.

During September, the sun moves about mid-month from the constellation Leo into Virgo and remains there until the end of October. Mercury keeps pace with the sun through the same constellations, while Venus moves out of Gemini in early September, spends most of the month in Cancer, and moves into Leo for late September and October. Mars moves from Virgo into Libra in mid-September; Jupiter from Leo into Virgo; Saturn is in Virgo; Uranus in Libra; Neptune in Ophiucus; and Pluto in Bootes.

September 1: The star near the moon this morning is Aldebaran, in Taurus.

September 5: Venus stands just below the "nether" tip of the moon at dawn this morning. Watch from moonrise (about 3:00 A.M. daylight time) on to see the moon approach and pass the planet.

September 13: Jupiter is in conjunction with the sun and becomes a morning star. You may still be able to see Mars as an evening star to the right and below the crescent moon tonight.

September 22: An auspicious day! The sun arrives on the equatorial plane today, at the point in the constellation Virgo known as the autumnal equinox. That marks the end of summer and the beginning of autumn in the Northern Hemisphere. The date of the "effective" equinox, however, when day and night are equal (and the sun spends half its time above the horizon and half below) is September 26.

September 24: Look for exceptionally strong tides tonight, as perigee occurs just 15 hours after the harvest full moon.

September 28–29: The star close to the moon tonight and tomorrow morning from moonrise (about 10:00 P.M. daylight time) on is Aldebaran.

October 4–5: It will be worth getting up early on both mornings to see Venus, Regulus, and the moon in the east. Venus passes the star during the day on the 4th, and the crescent moon passes both star and Venus before they rise on the 5th.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you turn to face in other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the sky at about 11 to 12 P.M. on September 1; 10 to 11 P.M. on September 15; 9 to 10 P.M. on September 30; and 8 to 9 P.M. on October 15. It shows only planets and moon phases above the horizon at those times.

### RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes count as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# A Squirrel in Every Pot

*A dish that emerged from the cabins of pioneer America has undergone a drastic change*

**by Raymond Sokolov**

When Dr. Creed Haskins and several of his friends returned from a day's hunting in the woods of Brunswick County, Virginia, in 1828 or thereabouts, they found their loyal black retainer Uncle Jimmy Matthews stirring a stew he had concocted in their absence. They ate it, hesitantly at first, then smacked their lips and called for more. By then, it did not dampen their appetites to learn that Matthews's thick and flavorful ragout was made from nothing more than butter, onions, stale bread, seasoning, and a passel of squirrels the slave had shot that morning.

This, at any rate, is the legend of the origin of Brunswick stew, the most famous dish to emerge from the campfires and cabins of pioneer America. Brunswick stew is still prepared in big caldrons at church suppers, volunteer firehouse fund-raisers, and all manner of communal celebrations throughout the Southeast. But it is virtually never cooked according to the original recipe. Dr. Haskins began the eroding of his servant's invention when he added some brandy or Madeira to "give the stew a flavor." Then, probably about the turn of the century, well-meaning cooks domesticated Matthews's squirrel *pot-au-feu* still further by throwing in vegetables.

In his classic statement on the subject, made in 1907, Meade Haskins, a descendant of Uncle Jimmy's master, fulminated against this fancification: "Vegetables are not in the original Brunswick stew. Those who prefer vegetables add them after the stew is done, in their plates."

This Haskins also set down the pure and authentic recipe he had received from his father, Dr. A.B. Haskins:

> Parboil squirrels until they are stiff (half done), cut small pieces of bacon (middling), one for each squirrel; one small onion to each squirrel (if large, one to two squirrels), chopped up. Put in bacon and onions first to boil, while the squirrels are being cut up for the pot. Boil the above till half done, then put in butter to taste; then stale loaf bread, crumbled up. Cook then till it bubbles, then add pepper and salt to taste. Cook this until it bubbles and bubbles burst off. Time for stew to cook is four hours with steady heat.

Although this text is not as clear as one might like, it offers adequate proof of what Brunswick stew once was, before modern innovators turned it into a veritable succotash of corn and tomatoes and beans and what not (see recipe below). But vegetables are hardly the principal infraction against authenticity currently practiced in Brunswick County and almost everywhere else. Modern Brunswick-stew makers have not only added vegetables; they have eliminated the squirrel.

*Large kettles hold burgoo, a stewlike mixture of meat and vegetables.*

Now I am not here to claim that a Brunswick stew made with squirrel is superior in any way to Brunswick stew made with chicken. And I certainly have no wish to join battle with those who may have had the opportunity to become fans of variant recipes based on opossum, muskrat, or raccoon. I would merely like to have the chance to taste the original dish. But I doubt I will, unless some hunter favors me with a brace of squirrels. They would have to be wild, woodland squirrels, of course, not urban squirrels that have fed on garbage.

This requirement, which I insist on to preserve my health, did not concern pioneer Virginians, who enjoyed a pristine, rural life style and woods abounding in fat, nut-fed squirrels. Today, however, most of us live in town and our only regular access to traditional game meats is through commercial butchers and restaurants. The law forbids the sale of uninspected game animals that have been shot in the wild. The venison we eat in a restaurant has been produced, like beef or lamb, on a ranch, and lacks the special taste of wild meat. And since no one, so far as I know, has started raising squirrels commercially, that means that even in Brunswick County, Virginia, you will not find traditional Brunswick stew, except perhaps in the home of some backwoodsman with an eccentric passion for gastronomic folklore.

"I couldn't put squirrel in my Brunswick stew even if I wanted to," says Larry of Larry's Lunch, the only restaurant in Lawrenceville, Virginia, the Brunswick County seat. He doesn't even list the dish on his menu, but if you ask him, he will sell you a thick farrago of chicken (cooked until it has fallen apart), lima beans, to-

*A crowd of Kentucky picnickers feast on burgoo and barbecued mutton.*

matoes, and potatoes that turns out to be a peppery, sinus-clearing soup of a high order. Larry claims this is a definite improvement over the squirrel-based Brunswick stew he used to eat in his younger days on the farm.

Maybe so, but I wouldn't mind seeing for myself if truly authentic Brunswick stew is worth reviving. I apologize to those who find the notion of eating cute little furry squirrels positively repugnant. And I suspect that this sentimental revulsion is part of the reason that Americans from one end of Appalachia to the other have eliminated squirrel from their hunter's stews. The same thing has occurred in the case of burgoo, which is a stewlike potpourri of meat and vegetables invariably supplied at political rallies and other outdoor gatherings in Kentucky, as well as southern Indiana and Illinois. Some people think that burgoo began during the Civil War, when a soldier with a speech impediment created a stew from blackbirds in a 500-gallon copper caldron normally used for making gunpowder. The soldier meant to call his creation "bird stew," but he actually said "burgoo."

Others have looked for a French etymology. But "burgoo" was undoubtedly in use as early as 1740 to describe a porridge eaten by British sailors. The nautical English novelist Frederick Marryat has a sailor in his book *Peter Simple* (1834) say: "Mark my words, you burgoo-eating . . . trowsers-scrubbing son of a bitch!"

It is not hard to imagine how the British fleet hit upon burgoo as a name for oatmeal. Some sailors on shore leave in a Levantine port must have made contact with the wheat pilaf called burghul (or bulgur) and transferred the name, with a slightly distorted pronunciation, to their oatmeal. This Turkish burghul became Peter Simple's burgoo. And in America, the exotic and faintly pejorative word quite probably attached itself to a similarly mushy mess of pottage concocted ad libitum from available vegetables and meats, one of which was, in Daniel Boone's Kentucky, squirrel.

The modern history of Kentucky burgoo begins with a certain James T. Looney, a retired railroad engineer. At his mother's bidding, Looney gave up the perils of railroading for a grocer's career in Lexington and then turned his hand to burgoo. For forty years he catered burgoo to crowds as large as 10,000. Looney was Kentucky's "burgoo king" and so renowned in the Bluegrass State that a thoroughbred colt was named after him. Burgoo King, the horse, won the Kentucky Derby in 1932.

Success did not spoil Jim Looney. All his long life, he upheld the highest standards of burgoo cookery. He took the meats out of his giant kettles (one of them said to have been used for making saltpeter during the Revolutionary War) midway through the 24-hour cooking process and chopped them up before returning them to the kettles. "You find no strings in my burgoo," he said.

You would find no squirrel either, according to his recipe for burgoo for 5,000 people recently printed in the *Louisville Courier-Journal*:

> 800 pounds beef, 200 pounds fowl, 168 gallons canned tomatoes, 350 pounds cabbage, 6 bushels onions, 85 gallons tomato purée, 24 gallons carrots, 36 gallons canned corn, 1,800 pounds potatoes, 2 pounds red pepper, ½ pound black pepper, 20 pounds salt, 8 ounces Angostura bitters, 1 pint Worcestershire sauce, ½ pound curry powder, 3 quarts tomato catsup, and 2 quarts sherry.

Today, fiery hot burgoo is available at simple restaurants in Louisville and throughout the Ohio River Valley to the west, always without squirrel or other sylvan beasties. Perhaps this makes no difference. Modern, lunch counter burgoo is a fine thing, although it owes most of its character to its red pepper. I cannot help thinking, however, that a little gaminess would restore this country dish to a vanished glory.

I came to this conviction in Owensboro, Kentucky, a middling metropolis west of Louisville on the Ohio. Owensboro is the barbecue mutton capital of the world. Every May, carloads of ewes are cooked over pits of hickory at the Owensboro International Barbecue Festival. During the average summer, local Catholic parishes run through 800,000 pounds of mutton at fund-raising barbecues, where exclusively male chefs cook the meat over an open flame for eighteen hours or so. No one knows why the people of Owensboro have chosen mutton as their meat of preference over equally traditional beef, pork, venison, bear, elk, and buffalo. The proprietor of Hardman's on East 4th Street, one of sixteen barbecue places in a town of 50,000, says: "Mutton stands up to flame better. It has a hard skin. Lamb falls apart."

Mutton also tastes different from lamb. It has a feisty tang to it, a high, almost gamy flavor that can hold its own even against the heady amounts of red pepper commonly added to burgoo. As I sat in the Hardman's dining room, a tiny area with a few tables next to a cold-storage locker containing two dressed ewes, I ate a bowl of superbly muttony burgoo and speculated that when the venison and buffalo became scarce at the end of the last century, Owensboro barbecue chefs, who were even then attracting trainloads of hungry tourists each spring and summer, turned to mutton as the best commercially available substitute for game meats at their famous cookouts.

Once they had established mutton as the main meat for barbecue, it was the natural thing to use some of it for burgoo. Mutton could give burgoo the same oomph that squirrel and opossum had formerly provided. There is no proving this, but if you want to taste a very reasonable facsimile of an authentic American hunter's stew without bagging a squirrel, stop over in Owensboro some time for mutton burgoo.

*Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.*

### Cissy's Burgoo

(Courtesy of the *Louisville Courier-Journal*)

| | |
|---|---|
| 2 | pounds pork shank |
| 2 | pounds veal shank |
| 2 | pounds beef shank |
| 2 | pounds breast of lamb |
| 1 | 4-pound hen |
| 8 | quarts water |
| 1½ | pounds Irish potatoes |
| 1½ | pounds onions |
| 1 | bunch carrots, scraped and chopped |
| 2 | green peppers, seeded and chopped |
| 2 | cups chopped cabbage |
| 1 | quart tomato purée |
| 2 | cups whole corn, canned or fresh |
| 2 | pods red pepper |
| 2 | cups diced okra |
| 2 | cups lima beans |
| 1 | cup diced celery |
| | Salt, Cayenne, Tabasco, A-1 Sauce, Worcestershire to taste |
| | Chopped parsley |

Put all the meat into cold water and bring slowly to a boil. Simmer until meat falls from the bones. Remove and chop up meat, discarding bones. Pare and dice potatoes and onions. Return meat to stock and add all vegetables (except parsley). Allow to simmer until thick. Burgoo should be very thick but still soupy. Season as you go along, but not too much, until it is almost done. Stir frequently with a long-handled wooden spoon during the early stages and almost constantly after it thickens. Add chopped parsley at the end.

This is made in a four-gallon kettle and cooked approximately ten hours. The time can be broken up by cooking the meat the first day and adding the vegetables the second day.

Yield: 60 servings

### Brunswick Stew—1975

(A synthesis of several traditional recipes, as compiled by Gay Neale in *Brunswick County, Virginia, 1720–1975.*)

| | |
|---|---|
| 1 | 3-pound chicken |
| 2 | pieces of celery |
| 1 | small onion |

Add a quart of water and simmer until meat is tender. Cool. Discard celery. Remove meat from bones and shred into small pieces. Then add:

| | |
|---|---|
| ¼ | stick butter |
| 1 | cup chopped onion |
| 1 | quart butterbeans (canned or frozen are good; fresh is better) |
| 1 | quart corn (whole kernel canned or frozen or fresh) |
| 2 | quarts tomatoes |
| 3 | medium potatoes, diced |

Continue cooking over mediu heat, adding water if necessary an stirring occasionally until separat identity of ingredients is no longe apparent—at least five hours. Seaso with salt, red pepper, and more blac pepper than seems sensible—at leas 2 teaspoons. Thicken with bread crumbs, crackers, or biscuit crumbs

Yield: 4-6 servings

In The Classic Tradition

Cabinetmaker's screwdrivers like these were used by Hepplewhite, Sheraton and Duncan Phyfe in the 18th century — The Golden Age of Furniture. They've been aptly called "Working Works of Art."

Comfortable oval beech handles. The flat area of the upper blade can take a wrench for extra turning power. Blade lengths: 2½, 3, 4, 5 and 6". Made in England. Backed by our 30 day **money back guarantee.** The five piece set: $24.95.

Since 1966, **Gordon C. Haber** has been conducting an intensive field study of wolves and grizzly bears and their ungulate prey—moose, mountain sheep, and caribou—in the Denali (Mount McKinley) region of Alaska. With more than 10,000 hours of observations under his belt, he is planning to continue the study. Haber received his Ph.D. in zoology from the University of British Columbia, and formerly taught biology at Anchorage Community College. He does consulting work on ecological matters and is also the owner and operator of a wilderness lodge and guide service in the Brooks Range of northwest Alaska.

Since Erbaba, the site of their archeological excavations, is in an opium-producing region of Turkey, **Jacques Bordaz** and **Louise Alpers Bordaz** have observed the many uses to which local villagers put the opium poppy plant and the effects of government regulation on opium poppy cultivation. The authors' archeological research concerns the development of animal and plant domestication and sedentism. In addition, they study traditional crafts and life styles in contemporary Turkey for the light they may shed on archeological interpretation. In 1971 they produced a short film, *Stone Knapping in Modern Turkey.* Jacques Bordaz is an associate professor of anthropology at the University of Pennsylvania; Louise Alpers Bordaz is an assistant professor in Columbia University's Department of Art History and Archaeology.

With this $25 rebate, Minolta's most economical compact SLR is now even more economical. So it's an incredible value. Because it has a remarkable combination of features found in no other camera in its class.

It's easy to get clear, sharp pictures with the XG-1 because it's a fully automatic 35mm camera that sets itself electronically. It also gives you manual over-ride, an LED shutter-speed display in the viewfinder, and an automatic shutter-lock to prevent over-exposed pictures.

The XG-1 accepts more than 40 interchangeable Minolta lenses and optional accessories like an auto winder and electronic flash.

Talk to your Minolta dealer today for details about the XG-1 rebate from Minolta. But hurry. This is a limited offer.

**$25 REBATE**

**James H. Shaw** has done fieldwork on wood ducks in Connecticut, red wolves in Texas, coyotes in Oklahoma, and giant anteaters in Brazil. An associate professor of wildlife ecology at Oklahoma State University, Shaw wrote about his work on red wolves in the December 1977 issue of *Natural History* ("The Wolf That Lost Its Genes"). He reports, "Tracy Carter and I met at the American Society of Mammalogists meeting in 1975, and I visited her while she was a Peace Corps volunteer in Brazil. We became interested in anteaters and developed field studies together. Our relationship is not exclusively professional, however, as we were married on December 28, 1977."

**Tracy S. Carter** received her Ph.D. in zoology from Michigan State University. In addition to serving as a Peace Corps volunteer in Brazil, she was an expedition leader on a project that studied the burrow characteristics and food habits of armadillos. Carter and Shaw plan to do research on the carnivores of the Brazilian National Park, Serra da Canastra.

**Phillip E. Playford** first became interested in stromatolites when he visited Hamelin Pool, Western Australia, as a member of an oil exploration team, and found these strange algal structures growing there. He has since carried out extensive research on these "living fossils," as well as on dead stromatolites in ancient reefs. Playford, who holds a B.Sc. in geology from the University of Western Australia and a Ph.D. from Stanford University, which he attended as a Fulbright scholar, is currently deputy director of the Geological Survey of Western Australia. In 1978 he toured the United States and Canada as distinguished lecturer of the American Association of Petroleum Geologists.

In 1969 **Margaret B. Blackman's** dissertation adviser handed her a photograph of the interior of a Haida Indian chief's house on America's Northwest coast, with the comment: "Why don't you see what you can do with this." After a search that led from the Queen Charlotte Islands through the photo archives of North America to London, Blackman completed her doctoral dissertation on recent Haida cultural history as seen through early photographs. She is now associate professor of anthropology at the State University of New York College at Brockport. Summer finds her in British Columbia, working on various field and archival research projects.

Speak French like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can make a start on learning to speak French just as these diplomatic personnel do—with the Foreign Service Institute's Basic French Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far *the most effective way* to learn French at your convenience and at your own pace.

The Basic French Course consists of a series of audio cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course you'll find yourself learning and speaking entirely in French!

*This course turns your cassette player into a "teaching machine."* With its unique "pattern drill" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Introductory Basic French Course comes in two parts. Part A provides an introduction to the simpler forms of the language plus a basic vocabulary. Part B introduces more complex structures and additional vocabulary.

You may order one or both parts of the Basic French Course.

☐ Basic French, Part A. 11 cassettes (16 hours) and 200-page text, $115.
☐ Basic French, Part B. 18 cassettes (25½ hours) and 300-page text, $149.

(New York State residents add sales tax)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail it with your name and address and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's French course is *unconditionally guaranteed*. Try it for three weeks. If you're not convinced it's *the fastest, easiest, most painless way to learn French*, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us

# Hopeful Monsters

*Teratology, the study of deformed births, helps explain normal growth.*

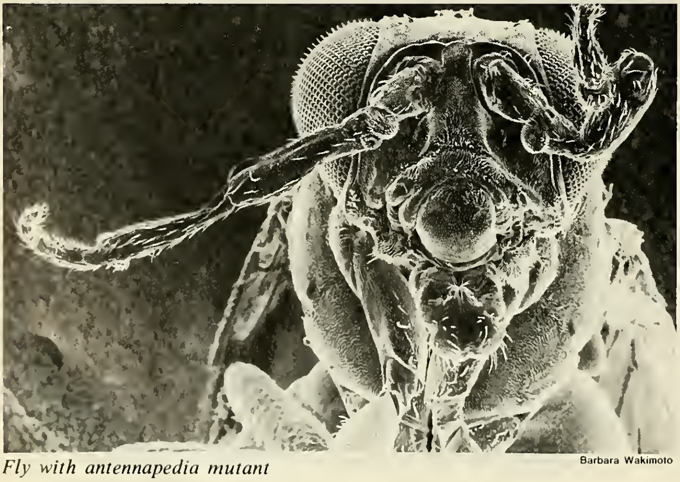
**by Stephen Jay Gould**

My grandfather, who taught me to play poker and watched the Friday night fights with me every week, once took me to one of the cruelest, yet most fascinating spectacles of decades now thankfully past—the rows of malformed people forced (by an absence of other opportunities) to display themselves to a gawking public at the Ringling Brothers sideshow.

The genteel and legitimate counterpart to such public cruelty is the vast scientific literature on deformed births—a subject dignified with its own formal name as teratology, literally, the study of monsters. Although scientists are as subject as all people to the mixture of awe, horror, and curiosity that draws people to sideshows, teratology has an important rationale beyond primal fascination.

The laws of normal growth are best formulated and understood when the causes of their exceptions can be established. The experimental method itself, a touchstone of scientific procedure, rests upon the notion that induced and controlled departures from the ordinary can lay bare the laws of order. Congenitally malformed bodies are nature's experiments, uncontrolled by intentional human art to be sure, but sources of insight nonetheless.

The early teratologists sought to understand malformations by classifying them. In the decades before Darwin, French medical anatomists developed three categories: missing parts (*monstres par défaut*), extra parts (*monstres par excès*), and normal parts in the wrong places. The folklore of monsters had long recognized the last category in tales of anthropophagi, maneaters with eyes in their shoulders and a mouth on their breast. Shakespeare alluded both to them and to some related colleagues in *Othello* when he spoke of "The Anthropophagi and men whose heads/Do grow beneath their shoulders."



*Fly with antennapedia mutant*

Barbara Wakimoto

But a classification is no more than a set of convenient pigeonholes until the causes of ordering can be specified. And here nineteenth-century teratology got becalmed in its own ignorance of heredity. The establishment of genetics in our century revived a waning interest in teratology, as early Mendelians discovered the mutational basis of several common deformities.

Geneticists had particular success with one common category in the old classification—normal parts in the wrong places. They studied their favorite animal, the fruit fly, *Drosophila melanogaster*, and found a variety of bizarre transpositions. In the first of two famous examples, the halteres (organs of balance) are transformed into wings, restoring to the aberrant fly its ancestral complement of four (normal flies, as members of the order Diptera, have two wings). In the second, legs or parts of legs replace a variety of structures in the head—antennae and parts of the mouth in particular. Mutations of this sort are called homeotic.

Not all misplacements of parts represent homeosis, and this restriction is a key to the evolutionary message I shall draw further on. William Bateson, who later invented the term ge-

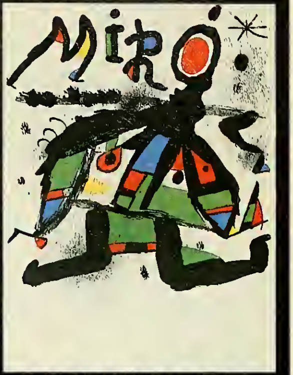
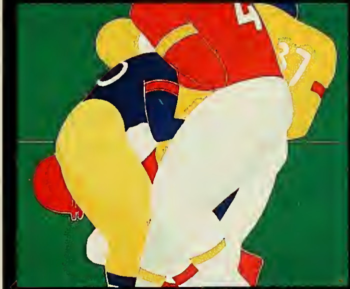
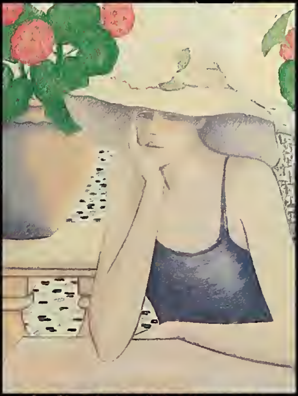
Tjelda Michas' *Cape Rose*, original serigraph. Signed limited edition of 225.



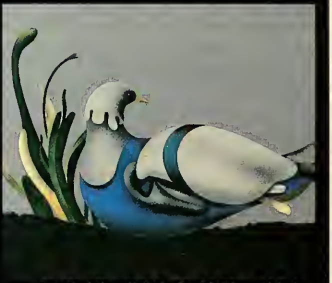
Joan Miró's *Miró Fantasy*, original lithograph. Signed limited edition of 75.



Thom de Jong's *All-Star Wars*, original etching. Signed limited edition of 175.



Jean-Pierre Cassigneul's *Les Géraniums*, original lithograph. Signed limited edition of 100.



Jean-Paul Donadini's *La Perdrix Bleue*, original lithograph. Signed limited edition of 225.

In your own home, you can exhibit original work by artists who are represented in the world's great museums and galleries.

Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, lithographs, woodcuts, and silkscreen prints.

Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.

(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal*, *Business Week*, *Money*, AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.

You'll find out about the special pleasure of owning original art, instead of just visiting it.

netics, defined as "homeotic" only those parts that replace an organ having the same developmental or evolutionary origin (the word comes from a Greek root for "similar"). Thus, halteres are the evolutionary descendants of wings, while insect antennae, mouthparts, and legs all differentiate from similar precursors in the embryonic segments, and all presumably evolved from an ancestor with a pair of simple and similar appendages on each adult body segment. We might refer to homeosis if a human developed a second pair of arms where his legs should be, but an extra pair of arms on the chest would not qualify.

Homeotic mutants are found on all four pairs of chromosomes in *D. melanogaster*. A recent review by W.J. Ouweneel (*Advances in Genetics*, vol. 18, 1976) includes a list that runs to three full pages. But the two most famous, best studied, and elaborate sets of homeotic mutations both reside on the right arm of the third chromosome.

The first set, called the bithorax complex and abbreviated BX-C, regulates the normal development and differentiation of the fly's posterior body segments. The larval fly is already divided into a series of segments, initially quite similar, that will differentiate into specialized adult structures. The first five larval segments build the adult head (the first forms anterior parts of the head; the second, the eyes and antennae; and the third through fifth, the various parts of the mouth). The next three segments, $T_1$, $T_2$, and $T_3$, form the thorax. Each will bear a pair of legs in the adult, building the normal insect complement of six. The single pair of wings will differentiate in $T_2$.

The next eight segments ($A_1$ through $A_8$) form the adult's abdomen, while the final, or caudal, segment ($A_9$ and $A_{10}$) will build the adult's posterior end. If all the genes of BX-C are deleted from the third chromosome, all larval segments behind the second thoracic ($T_2$) fail to differentiate along their normal route and seem to become second thoracic segments themselves. Thus, the presence of normal BX-C genes appears to be a precondition for the ordinary development of all segments behind the second thoracic. If the adult survived, it would be a wonder to behold, with (presumably) a pair of legs on each of its numerous posterior segments. But this deletion is, in geneticist's jargon, "lethal," and the fly dies while still a larva. We know that the posterior segments of such aberrant flies are slated to develop as second thoracics because incipient differentiation within the larval segments serves as a sure guide to their later fate. (*Drosophila* geneticists, after seventy years of practice, have developed a remarkable bag of tricks for recognizing [or inducing] mutations, combining them, and fostering larger changes in the structure of chromosomes. Flies with small missing parts [deletions] of various chromosomes arise now and again, and these are avidly sought and propagated for their evident value in assessing the causes of normal development by charting malformations that arise when genes are missing.)

The bithorax complex consists of at least eight genes, all located in sequence right next to each other (see review in *Nature*, 1978, p. 565, by E.B. Lewis). Edward B. Lewis, the distinguished geneticist from the California Institute of Technology who has spent twenty years probing the complexities of BX-C, believes that these eight genes arose as repetitions of a single ancestral gene and then evolved in different directions. (I must defer the fascinating subject of gene duplication and its evolutionary significance to a later column.) Just as the entire deletion of BX-C produces the striking homeotic effect of converting all posterior segments to second thoracics, several mutations in the eight genes produce homeotic results as well. The most famous mutation, called bithorax and commandeered as a name for the entire complex, converts the third thoracic segment into a second thoracic. Thus, the adult fly develops with two second thoracics and two pairs of wings, instead of one pair and a pair of halteres behind. (It is misleading to state that halteres "turn into" wings. Rather, the entire segment normally destined to be a third thoracic, and to produce halteres, develops as a second thoracic and builds wings.) In another mutation, called bithoraxoid, the first abdominal segment develops as a third thoracic, builds a pair of legs, and yields a fly with more than the usual insect number of six.

Lewis has proposed an interesting hypothesis for the normal action of BX-C genes. He believes that they are initially repressed (turned off) in the larval fly. As the fly develops, BX-C genes are progressively derepressed (turned on). The BX-C genes act as regulators—that is, they do not build parts of the body themselves but are responsible for turning on the structural genes that do code for building blocks. Adult form reflects the amount of BX-C gene-product in an embryonic segment; the more BX-C, the more posterior in appearance the segment. Lewis then argues that BX-C genes are derepressed in sequence, from the anterior point of their action (the third thoracic segment) to the back end of the animal. When a BX-C gene turns on, its product accumulates in a given segment and, simultaneously, in all segments posterior to it. BX-C first turns on in the third thoracic, and its product accumulates in all segments from the third thoracic to the posterior end. The next BX-C gene turns on in the next posterior segment, the first abdominal, and its product accumulates in all segments from the first abdominal to the posterior end. The next gene turns on in the second abdominal, and so forth. Thus, a gradient of BX-C product forms, with lowest concentration in the second thoracic and increasing amounts in a posterior direction. The more gene product, the more posterior in appearance the form of a resultant segment.

This hypothesis is consistent with the known homeotic effects of BX-C mutations. If BX-C is deleted entirely, it supplies no gene product, and all segments behind the second thoracic differentiate as second thoracics. In a mutation with opposite effect, all the BX-C genes are turned on at once and in all segments of their action; all segments affected by it then differentiate as eighth abdominals.

The second outstanding set of homeotics is also named for its most famous mutation—the antennapedia complex, or ANT-C. The fine structure of this complex has recently been elucidated in a series of remarkable experiments by Thomas C. Kaufman, Ricki Lewis, Barbara Wakimoto, and Tulle Hazelrigg in Kaufman's laboratory at the University of Indiana. (I thank Dr. Kaufman for introducing me to the literature of homeosis and for patient and lucid explanations of his own work.) The BX-C genes regulate the morphology of segmentation from the third thoracic to the posterior end; ANT-C also affects the third thoracic, but then regulates development in the five segments anterior to it (the

**a $69.50 value**

Yours for only **$2.97**

When you join the **Natural Science Book Club** for a trial period and agree to take 3 more books—at handsome discounts—over the next 12 months.

Find the answers to virtually *all* your scientific questions, in the new, thoroughly updated and expanded fifth edition of Van Nostrand's SCIENTIFIC ENCYCLOPEDIA. It has been hailed by *The New York Times* as "an amazing book . . . For both the general and scientific reader."

Thousands of photos, diagrams, graphs and charts completely illuminate the ENCYCLOPEDIA's clear and thorough coverage of every scientific field—including archaeology, astronomy, general science, biology, medicine, physics, ethology and meteorology. Whether you're looking for a basic explanation of earthquakes or a comprehensive analysis of nuclear reactors—you'll find it all in Van Nostrand's SCIENTIFIC ENCYCLOPEDIA.

**What is the Natural Science Book Club?** A unique book club devoted to bringing you exciting, refreshingly different books on all areas of the natural sciences. From the life story of early man to the death of a solar system . . . from the largest mammals to the invisible kingdom of microscopic organisms . . . all the wonders of our natural world are revealed.

Begin enjoying the Club's benefits by accepting Van Nostrand's SCIENTIFIC ENCYCLOPEDIA. It's the perfect guide to the marvels of nature . . . and it's a great bargain, too!

- **Enlarged and exhaustively updated edition of an acclaimed classic.**
- **A mammoth 9″ x 12″ volume covering everything scientific from abacus to zygote, in 2,370 pages, 7,200 editorial entries, 8,000 cross-references and 2.2 million words ... plus 2,450 photos, diagrams, and charts as well as 550 tables.**
- **Authoritatively compiled by over 180 internationally respected scientific experts.**

other two thoracics and the three that produce parts of the mouth). If the entire complex is deleted, then all three thoracic segments begin to differentiate as first thoracics (while the abdominals, regulated by BX-C, develop normally). Apparently, the genes of ANT-C normally turn on in the second thoracic segment and trigger the proper development of the second and third thoracics.

Kaufman and his colleagues have found that ANT-C consists of at least seven genes, not all with known homeotic effects, lying right next to each other on the right arm of the third chromosome in *D. melanogaster*. The genes are not named for their normal effects (which, after all, just yield an ordinary fly bearing nothing special for recognition) but for their rare homeotic mutations. The first, the antennapedia gene, regulates differentiation of the second thoracic segment, and normally turns on there to accomplish its appointed function. A series of mutations has been detected at this locus, all with homeotic effects consistent with this interpretation of its normal function.

One dominant mutation, antennapedia itself, has the bizarre effect (as its name implies) of producing a leg where an antenna ought to be. This wayward appendage is not any old leg, but clearly a second thoracic. The antennapedia mutation apparently works by turning on in the wrong place—the antennal segment—rather than in the second thoracic segment.

Another dominant mutation, called extra sex combs, leads to the appearance of sex combs on all three pairs of legs, not only on the first as in normal flies. This morphology is not simply the result of a gene that makes sex combs (contrary to popular belief, very few genes simply "make" individual parts without series of complex and coordinated effects). It is a homeotic mutation. All three thoracic segments differentiate as first thoracics, and the fly has, literally, three pairs of first legs with their attendant sex combs. (The entire deletion of ANT-C also causes the three thoracics to differentiate as first thoracics, but this deletion is lethal and the fly dies in its larval stage. Flies with the extra sex comb mutation do live to become adults.) The extra sex comb mutation probably operates by suppressing the normal action of its gene. Since normal action causes the second thoracic segment to differentiate properly, suppression induces all three thoracics to develop as first thoracics.

The second gene of ANT-C is named for its prominent mutation, reduced sex comb. This homeotic mutation, contrary to the effect of its neighbor extra sex comb, causes the first thoracic segment to differentiate as a second thoracic. Only first thoracic legs bear sex combs in *D. melanogaster*. The next three genes do not have known homeotic effects, and their inclusion within ANT-C is something of a puzzle. One deletes a number of embryonic segments in its most prominent mutation, another interferes with normal development of the maxilla and mandible of the mouth, while the third produces a curiously wrinkled embryo.

The sixth gene of ANT-C is named for the other famous homeotic mutant of this complex—proboscipedia, discovered in 1933 by two of the century's most famous geneticists, Calvin Bridges and Theodosius Dobzhansky. Six mutations have been detected at this locus; most, like proboscipedia itself, produce legs where parts of the mouth should develop. The seventh and last (known) gene of ANT-C lacks homeotic effects in its mutant form and produces severe constrictions at segment boundaries in the larva. It is lethal.

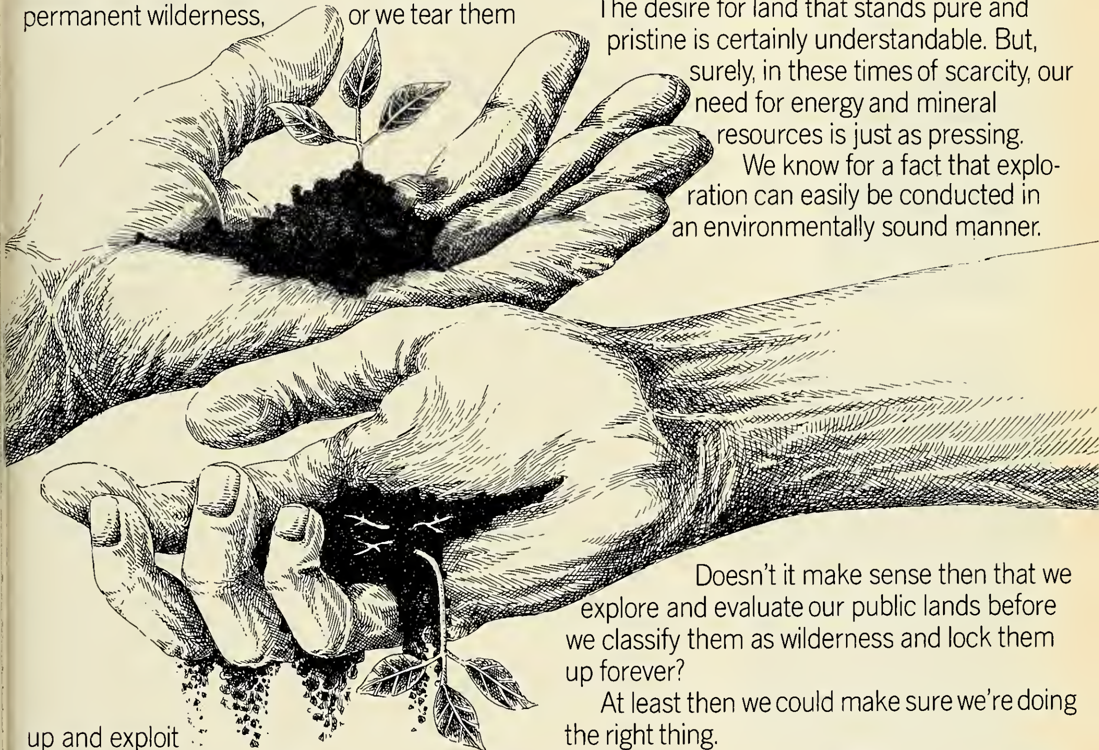
Homeosis is not a peculiarity of fruit flies, but seems to be a general phenomenon, at least in arthropods. A set of mutations analogous (or even homologous) with the bithorax homeotics of *Drosophila* occurs in the silk moth *Bombyx* (order Lepidoptera; flies belong to the order Diptera). Two species of *Tribolium*, the flour beetle (order Coleoptera), exhibit mutations with effects that mimic the ANT-C homeotics of *Drosophila*. One set, in *Tribolium castaneum*, acts like antennapedia and produces a graded series of partial replacements of antennae by legs, ranging from tarsal claws on the eleventh antennal segment to the virtual replacement of an entire antenna with a foreleg. Another, in *T. confusum*, acts like proboscipedia and substitutes legs of the first thoracic segment for mouth structures known as labial palps. In the cockroach *Blatella germanica*, a homeotic mutant produces rudimentary wings on the first thoracic segment. No modern insect normally bears wings on its first thoracic segment, but the earliest winged fossil insects did!

Homeosis is easiest to demonstrate

# Some want to keep our land unspoiled. Some want to explore it. We want to explore without spoiling.

There's a strange either-or proposition building up in this country.

It's one that says either we completely preserve our public lands by turning them into permanent wilderness, or we tear them up and exploit them to the fullest for their natural resources.



We've got to believe there's an acceptable middle ground between these two extremes.

Because neither is really in the long-range interest of our country.

Look at the facts. Our public lands currently supply only 10% of our energy. Yet they actually contain about half of all our known domestic energy resources—vast amounts of coal, oil shale, tar sands, crude oil and natural gas.

And what are we doing about it?

In recent years, through legislation or administrative action, 130 million acres of the 760 million that the federal government owns have been completely withdrawn from exploration of any kind.

And there's more legislation pending which, if passed, will mean that, in total, as much as 71% of our public land could be set aside.

All without ever finding out first, through preliminary exploration, what the resource potential of that land really is.

The desire for land that stands pure and pristine is certainly understandable. But, surely, in these times of scarcity, our need for energy and mineral resources is just as pressing.

We know for a fact that exploration can easily be conducted in an environmentally sound manner.

Doesn't it make sense then that we explore and evaluate our public lands before we classify them as wilderness and lock them up forever?

At least then we could make sure we're doing the right thing.

To continue in the direction we're presently going could well be one of the most self-defeating steps we've taken in this century.

Or so it seems to us at Atlantic Richfield.

**There are no easy answers.**

ARCO

Atlantic Richfield Company

in arthropods with their characteristic body plan of discrete segments with different and definite fates in normal development, but common embryological and evolutionary origins. Yet analogous phenomena have been noted again and again in other animals and plants with repeated parts. In fact, Bateson's first example after defining the term invoked vertebrae in the human backbone. All mammals (except sloths, but including giraffes) have seven cervical, or neck, vertebrae (they are awfully large in giraffes). These are followed by dorsal, or rib-bearing, vertebrae. Bateson cites numerous cases of humans with ribs on the seventh, and even a few with ribs on the sixth, cervical vertebra.

Homeotic mutants are gripping in their weirdness, but what do they teach us about evolution? We must avoid, I believe, the tempting but painfully naïve idea that they represent the long-sought "hopeful monsters" that might validate extreme saltationist views of major evolutionary transitions in single steps (a notion that I, despite my predilections for rapid change, regard as a fantasy born of insufficient appreciation for organisms as complex and integrated entities). First of all, most homeotic mutations produce hopeless creatures. The legs that extend from antennal sockets or surround mouths in afflicted flies are useless appendages without proper neural and muscular hookups. Even if they did work, what could they accomplish in such odd positions? Secondly, the viable homeotics mimicking ancestral forms are not really forebears reborn. A bithorax fly bears the ancestral complement of four wings, but it attains this state by growing two second thoraxes, not by recovering an ancient pattern.

I believe that the lessons of homeosis lie first in embryology and then cycle back to evolution. As Tom Kaufman pointed out to me, they demonstrate in a dramatic way how few genes are responsible for regulating the basic order of developing parts in a fruit fly's body. Together, the ANT-C and BX-C complexes of *D. melanogaster* specify the normal development of all the mouth, thoracic, and abdominal segments—only the two anterior segments are not subject to their control. Each complex contains only a handful of genes and each handful may have evolved from a single ancestral gene that repeated itself several times. When these genes mutate or are deleted, peculiar homeotic effects arise that usually throw development awry and lead to death.

Most importantly perhaps, these homeotic complexes display the hierarchical way in which genetic programs regulate the immense complexity of embryonic development, recognized since Aristotle's time as biology's greatest mystery. The homeotic genes do not build the different structures of each body segment themselves. This is the task of so-called structural genes that direct the assembly of proteins. The homeotics are switches or regulators; they produce some signal (of utterly unknown nature) that turns on whole blocks of structural genes.

Yet, at a higher level, some master regulator must be responsible for turning on the homeotics at the right time and in the right place, for we know that many homeotic mutations are mistakes in placement and timing (in antennapedia, a gene that regulates normal development in the second thoracic segment turns on in the antennal segment instead). Perhaps this master regulator is no more than a gradient of some substance running from the front to the back end of a larval fly; perhaps the homeotic regulators can "read" this gradient and turn on in the right place by assessing its concentration. In any case, we have three hierarchical levels of control: the structural genes that build different parts in each segment, the homeotic regulators that switch on the blocks of structural genes, and the higher regulators that turn on the homeotic regulators in the right place and at the right time.

If embryology is a hierarchical system with surprisingly few master switches at high levels, then we might draw an evolutionary message after all. If genetic programs were beanbags of independent genes, each responsible for building a single part of the body, then evolution would have to proceed bit by bit, and any major change would have to occur slowly and sequentially as thousands of parts achieved their independent modifications. But genetic programs are hierarchies with master switches, and small genetic changes that happen to affect the switches might engender cascading effects throughout the body. Homeotic mutants teach us that small genetic changes can affect the switches and produce remarkable changes in an adult fly. Major evolutionary transitions may be instigated (although not

finished all at once as hopeful monster enthusiasts argue) by small genetic changes that translate into fundamentally altered bodies. If classical Darwinian gradualism is now under attack in evolutionary circles, the hierarchical structure of genetic programs forms a powerful argument for the critics.

In this context, we consider the hypothetical major steps in insect evolution and recognize that homeotic mutants may help to illuminate them. Insects, with their relatively few, differentiated segments, probably evolved from an ancestor with more numerous and less differentiated segments. Initially, these less differentiated segments each bore a pair of legs (the antennae and mouthparts of modern insects are modified legs). Insects evolved by suppressing legs on the posterior segments and modifying them to antennae and mouthparts on the anterior segments. The major homeotic complexes of *Drosophila* seem to regulate just these changes—and with a minimum of genetic information. BX-C controls the posterior appendages with their suppressed legs, and its deletion causes these segments to begin a differentiation as second thoracics with incipient legs. The major mutants of ANT-C replace structures that were once legs with legs. The nature of homeotic changes is not capricious, but follows evolutionary channels.

Even the bizarre homeotics may not be devoid of evolutionary information. When Bridges and Dobzhansky described proboscipedia in 1933, they noted that a large set of coordinated changes—quite apart from the spectacular appearance of legs—all brought the mouthparts closer to the standard form of biting insects from which the flies presumably evolved. (Dobzhansky, who died just a few years ago, was the greatest evolutionary geneticist of our times. Fancy, quantitative lab work often wins all the kudos while field naturalists, with their detailed and specific knowledge, are unfairly dismissed as stamp collectors. Dobzhansky's life proves how contemptible this prejudice is. Geneticists had been describing homeotic mutants for years, but none had the knowledge to recognize the subtle morphological effects that require a trained taxonomist's eye to comprehend. Dobzhansky, the finest geneticist of them all, was a trained taxonomist and field biologist who began his work by specializing on the systematics of the Coccinellidae, or lady beetles. There is no substitute for detailed knowledge of natural history and taxonomy.)

If anyone has wondered whether homeotic mutants must find their significance only in highfalutin realms of evolutionary speculation, I close with an arresting fact. A homeotic mutation has been found in the biting mosquito *Aedes albopictus*. Yes, you guessed it. This mutation converts part of the biting apparatus into a pair of legs! The six stylets that actually pierce our skin are unaffected, but the labella, the structures that surround the stylets and contain tactile and chemosensory hairs, are converted to legs with tarsal claws at their tips. These mosquitos cannot pierce skin, both because they lack the tactile and chemosensory hairs that locate the right spot and because the stylets get entrapped in the misplaced legs.

What a wonderful and joyous idea in a world inundated with bad news—an ouchless mosquito with an extra pair of legs. Oh, don't raise your hopes. They won't replace the normal ones. First of all, they die because they cannot feed (although they can be artificially maintained on blood-soaked cotton balls). Even if they learned to feed by lapping instead of piercing, they would be no match for the normal kind because they have longer larval lives, increased pupal mortality, and a significant decrease in adult longevity. Still, these are the curious facts that nurture hope in parlous times—in this case, and with only a little poetic license, an enormous advantage (if only for another long-suffering creature) of putting a foot in one's mouth.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

My article, "Dr. Down's Syndrome," published in the April 1980 issue, was an expansion of part of a chapter on nineteenth-century anthropometry that I wrote in 1978, and will appear in my forthcoming book, *The Mismeasure of Man*. Dr. Carolyn Fluehr-Lobban of Rhode Island College, who wrote an excellent and far more extensive article on Down's Syndrome in 1979—"Down's Syndrome (Mongolism), the Scientific History of a Genetic Disorder"—has asked me to add this citation of her manuscript to the acknowledgement of her help already published in my original article.

# Fatness, Puberty, and Fertility

*Stored fat appears to regulate reproductive ability in the human female*

**by Rose E. Frisch**

Charles Darwin observed, more than a hundred years ago, that "hard living retards the period at which animals conceive" and, conversely, that "the more vigorous and better-nourished individuals of a species would be ready to breed in the spring before the others." He also noted that domestic animals, which have regular, plentiful food without working to get it, are more fertile than the corresponding wild animals, and that an individual animal's fertility is affected by variations in the amount of food. Darwin's common-sense description of the relationship between nutrition, "hard living," and fertility also applies to human beings, as an examination of historical trends and current findings will show.

A.M. Carr-Saunders, in his classic book *The Population Problem*, gives many examples from hunting and fishing societies to show that poor living conditions limit human fecundity, or reproductive ability, and better conditions enhance it. Recognizing the general principle for all species, he states:

> Fecundity has been spoken of as if it was fixed at a certain strength for each species. As a matter of fact, it varies within fairly wide limits—increasing with better conditions. In this fact lies the explanation of the increase of species under favorable conditions which has often been observed, although when conditions are less favorable, there is little or no evidence of starvation among such species.

When food supplies are inadequate, women and men, like other animals, are less fertile. When food intake is very low, reproduction stops. The individual does not reproduce the species at any cost.

Differences in the natural fertility of human populations have long been recognized. These have usually been attributed to differences in length of birth intervals or variation in general health and food intake, without explanation of how this regulation is achieved. In recent years, scientists have sought to specify the biological mechanisms involved. My own research has been concerned with the discovery, with Janet W. McArthur, that the onset and maintenance of regular menstrual cycles in women are dependent on the attainment and maintenance of a minimum weight for height, apparently representing a critical level of fat storage. A particular body composition—a certain ratio of fat to lean or of fat to body weight—proves to be an important determinant of fecundity in the human female.

We found that a woman who loses about 10 to 15 percent of her body weight—thereby losing about a third of her body fat—becomes amenorrheic, that is, her menstrual cycles cease. An excess of body fat also affects menstrual function, since other studies have shown that very obese women also become amenorrheic or have irregular cycles. Too little fat or too much fat, therefore, is associated with a disruption of female reproductive ability. My research, which has been concerned with the effects of excessive thinness, suggests that a minimum level of stored, easily mobilized energy, such as fat, is necessary for ovulation and menstrual cycles and for a successful pregnancy and lactation (nursing). Chronic or acute undernutrition and the energy drain of hard physical exercise can directly affect female fertility far more than has been realized. Male fertility also is affected by undernutrition, but in a pattern different from that for women.

Quantitative interest in the body in relation to nutrition, growth, and reproductive ability in both sexes first became strong in the nineteenth century, probably inspired by the pioneer work of the Belgian mathematician Adolphe Quetelet. In the earlier Malthusian view, human reproductive power was an irrepressible force, fulfilling itself regardless of circumstance, to be cut down by the positive check of increased mortality or held in check by the moral restraint of late marriage. In contrast, the medical and biological literature of 1850 to 1880 assumed that reproductive ability in both sexes is directly related to the state of vigor or decrepitude of the reproducing individuals. British medical texts up to about 1885 emphasized that constitutional conditions are more important, and more prevalent, causes of sterility than diseases of the organs. Doctors realized that sterility may serve a protective function: if a woman deficient in reproductive energy did get pregnant, there would be a high risk of miscarriage or of sickly children or of the death of the mother.

The degree of pinguidity, or fatness, was known to be important in relation to sterility. "She's too thin" to get pregnant or to menstruate regularly was a common observation, especially in association with tuberculosis or chlorosis, a virulent anemia common among working women. The prescription was to "recover her flesh" by puddings and roast meats, good wine, and fresh air and sun. "She's too fat to get pregnant" was also observed; in such cases, a light diet and exercise were prescribed. Alcoholism too was already correctly perceived as a cause of sterility.

Undernutrition and hard work were recognized as being related to the high incidence of menstrual disorders. About a quarter of the women working in mills apparently suffered from either retarded or suppressed menses, and about half of all married women between the ages of 20 and 45 were reported to have "diseases of the uterus," including amenorrhea. The main causes of amenorrhea, according to doctors, were those that "impair the constitutional tone and impoverish the blood": poor diet, disease (particularly tuberculosis and chlorosis), unsuitable employment, and cold and damp. Doctors noted that working-class women were underweight and amenorrheic because of poverty; upper-class women because of their desire to be fashionably thin. Stress ("violent fits of passion") was also implicated as a cause of amenorrhea.

Perhaps owing to their awareness of the life cycles of domestic animals, many nineteenth-century doctors re-

CUSTOMER INFORMATION FROM GENERAL MOTORS

# HOW TO HELP PROTECT YOUR CHILD'S LIFE

## CHILD RESTRAINT SYSTEMS IN CARS CAN LOWER THE RISK OF SERIOUS INJURY

The facts aren't pretty. Each year, more small children are killed in automobile accidents than in drownings, fires, or falls. And that's only part of the story. About 46,000 children under the age of five are injured in auto accidents every year. Experts estimate that the vast majority of these fatalities could have been prevented and most injuries reduced if Child Restraint Systems had been used. The tragedy is that less than 10% of all children in cars are properly restrained in child seats.

**An unrestrained child is vulnerable in an auto accident.** During its first few years, an infant is proportioned differently than an adult. That means small children are top-heavy—usually until the age of five.

If children aren't restrained during an accident, or even a sudden stop, they may tend to pitch forward, headfirst. Even in a minor collision a small child can be thrown against the car's interior, and serious injuries can occur.

**Holding a child in your arms is not a substitute for a Child Restraint System.** Some people think that by holding a child in a car they are protecting him or her. But safety experts disagree. In an accident, a child in a parent's arms can be crushed between the car's interior and the unrestrained parent. Even if the parent is wearing a seat belt, in a 30 mph collision a 10-pound child can exert a 300-pound force against the parent's grip. Chances are that even a strong adult won't be able to hold on to a child in such a situation.

**Child Restraint Systems are an effective way to protect a child in a car.**

General Motors makes two types of Child Restraint Systems: *The Infant Love Seat,* for infants up to 20 pounds; and *The Child Love Seat,* for children 20 to 40 pounds and up to 40 inches in height. They are available through any GM car or truck dealership and leading department and specialty stores. These have been designed by our safety engineers in consultation with pediatricians and medical experts. We believe they represent a significant development in child safety systems.

Ours aren't the only systems available. The important thing is to have a restraint system for your child and to use it correctly.

**Here's what to look for when you buy a Child Restraint System:** 1) For a child restraint, the seat should have a label certifying that it meets Federal Motor Vehicle Safety Standard #213. 2) An infant restraint should indicate on the label or in the literature that it has been dynamically tested. 3) Make sure that the seat is appropriately designed for your child's size and development. 4) For convenience and safety, the seat should attach easily but securely to your car, hold your child snugly, and be the one you're willing to use correctly. 5) It's a big help if the seat is easy to clean.

At General Motors, we're very concerned about safety. And we believe that every child has the right to the protection afforded by properly designed child seats and infant carriers. That's why we support efforts to enact reasonable mandatory child restraint laws.

Please make sure that when you have a child in the car, he or she is adequately protected. If you have a Child Restraint System, always use it. If you don't have child restraints, read your Owner's Manual and learn how the seat belts your car does have can be used to protect your child. And always remember to wear seat belts yourself. Because no matter how careful you may be, accidents can, and do, happen.

*Parallels may be drawn between the hen's fertile career and human reproduction, including the effects of improved nutrition, one factor behind the differences between 1865 and 1923 data.*

AMNH

alized that, in addition to the direct effects of nutrition and hard living on reproductive success, there is an optimal reproductive stage related to physical growth and the coordinated growth of the genital organs. J. Matthews Duncan, speaking before the Royal College of Physicians about a century ago, observed that if a female, human or cattle, is bred too young, "it is at the expense of the completion of normal growth" and may result in both inferior offspring and the death of the mother.

Duncan had studied the fertility of Scottish women in order to find the age of reproduction of least risk to the mother. He observed that the fertility of women gradually increases with age to a climax and then gradually wanes, similar to "the fertile career of the domestic hen." As in the hen, reproductive errors are more frequent at the beginning and end of the fertility curve, and underfeeding and overfeeding will diminish fertility.

The reproductive career of the mid-nineteenth-century British female began with menarche, the onset of menstrual cycles, at about 15 to 16 years of age. Age of menarche differed by social class: girls of the upper socioeconomic classes matured before the poorer girls. Today, the average age of menarche of British girls is about 13 years of age, while for girls in the United States the average age is 12.6 to 12.8. (It should be emphasized that any "average age" reflects a great deal of natural variation, and that even under optimal conditions, there are differences in individual rates of growth attributable to normal, genetic variation.) It was observed that following menarche there was a period of relative infertility, now termed adolescent sterility, or adolescent subfecundity. This period lasted until the completion of physical growth at about age 22, when the first stage of nubility, the "fitness for procreation," as Duncan described it, was attained. Then came the rise to the age of peak nubility, or "best fitness for procreation," at age 25 to 29. This was the age of full physical vigor when a woman had the best chance of surviving her first birth. The risk of maternal mortality and of infant mortality or congenital deformities, high at menarche, decreased up to the age of peak nubility and then increased as the mother became older.

The fertility curve descended gradually to the cessation of childbearing at about 40 years of age, and then to the cessation of menses, the menopause, at about age 47. The premenopausal "turning-off" period is analogous to the postmenarcheal "turning-on" period of adolescent subfecundity. In the mid-nineteenth century, these periods were of about equal length, six years. Nowadays, the period of adolescent subfecundity averages only three or four years, while the period of premenopausal subfecundity has increased to seven or eight years. Both types of reduced reproductive ability are characterized by the absence of ovulation or other disturbances of the normal cycle.

The average age of menopause in about 1850 was approximately 47 years, earlier than that of present-day, well-nourished women, for whom it

## 4 Good Reasons To Try The History Book Club

**Big cash savings.** Last year our members saved 33% on their Club purchases. Your total savings as a trial member, including this introductory offer, can be more than 50%.

**Liberal bonus plan.** You can qualify for added savings through bonus books, selected from our full list of 150-200 fine works.

**Exceptional quality.** In its 34 years, the Club has distributed over 1,000 books, including 81 award winners. Our books are the equal of publishers' editions, not economy reprints.

**Membership benefits.** A membership account will be opened for you, to which your purchases will be charged at the low member's prices. You need pay only after you have received your books. A postage-and-packing fee is added to each shipment. Every four weeks (13 times a year) for as long as we think you're interested, you will receive our *Review* containing descriptions of new and recent selections. If you want the Editors' Choice, do nothing; it will be sent automatically. If you want another book, or no book at all, return the card by the date specified. If you should receive an unwanted book because you had less than ten days to decide, you may return it and pay nothing. We guarantee postage.

## More fine books to choose from:

(First price is publisher's list. **Boldface** shows member's price.)

214. **Germany and the United States: A "Special Relationship?"** *By Hans W. Gatzke.* $17.50/**$12.50**

averages about 50 to 51. The extent of this secular, or long-term, change in the age of menopause—about three years—is comparable to the change in the age of menarche in the last one hundred years.

In the nineteenth century, lactation was understood to regulate the birth interval in the human female, as in other mammals, by retarding the birth of the next offspring. The length of the birth interval determines the ultimate size of the family and the health of the mother and child. A hundred years ago, the average birth interval of about two years was considered biologically natural. It was already known, however, that the birth interval lengthened as the mother became older and that women "low in fecundity" bred at greater intervals at all ages, beginning with the first birth.

The historical curve for reproductive ability, or procreative power as it was termed in the nineteenth century, is more speculative for males than for females, but the time of beginning and the peak are reasonably well estimated from the data on the times of fastest growth in height and completion of growth, in relation to the female ages. Peak fecundity in British males in the mid-nineteenth century occurred at about 31 to 33 years of age, compared to age 25 to 29 for females. Genarche, the male equivalent of menarche, most probably occurred at about age 17 to 18.

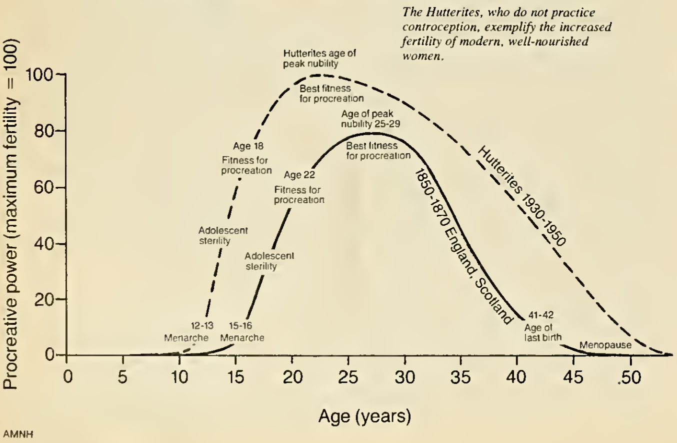
Most men of the British lower social classes did not complete height growth until age 23 to 25. Even upper-class men were relatively late, 21 to 23 years old, compared to the present age of completion, 18 to 20, for well-nourished males in Western countries. Most British women did not complete their growth in height until age 20 to 21, compared to age 16 to 18 today.

Height data from Norway corroborate the class differences in growth and maturation found in mid-nineteenth-century Britain. In addition, the data show the direct effect of an increase in food supply (for example, the introduction of the potato) in valleys in Norway on the height of army recruits and on the age of male and female sexual maturation. The better the food supply, the earlier the maturation.

The age, height, and weight for army recruits were much discussed and carefully chosen in relation to age of adult physical maturation. The British army doctors who passed on recruits were told that too young an age of recruiting and not enough men at the "acme of virility"—35 years—led to catastrophe. Poorly fed recruits, the ones most likely to join the army to collect a bounty, were a bad risk since they were physiologically younger than their chronological age. These men were slow to complete their growth, so their "limb power" and heart volume were immature. On long marches these were the men who fell by the wayside or had to be hospitalized. Recruits should be at least 20 to 21 years old—then they will be bone and muscle, "not almost gristle," as Lord Henry Hardinge complained of recruits under 19 years old arriving in the Crimea.

Although historical data do not exist on the direct effects of nutrition on male reproduction, we know from modern studies that severe undernutrition results in loss of libido, a decrease in prostate fluid, a decrease in sperm mobility and longevity, and eventually, the cessation of sperm production, in that order. Undernutrition also delays the onset of sexual maturation in boys, as in girls.

The trend toward a longer and more fertile reproductive career



*The Hutterites, who do not practice controception, exemplify the increased fertility of modern, well-nourished women.*

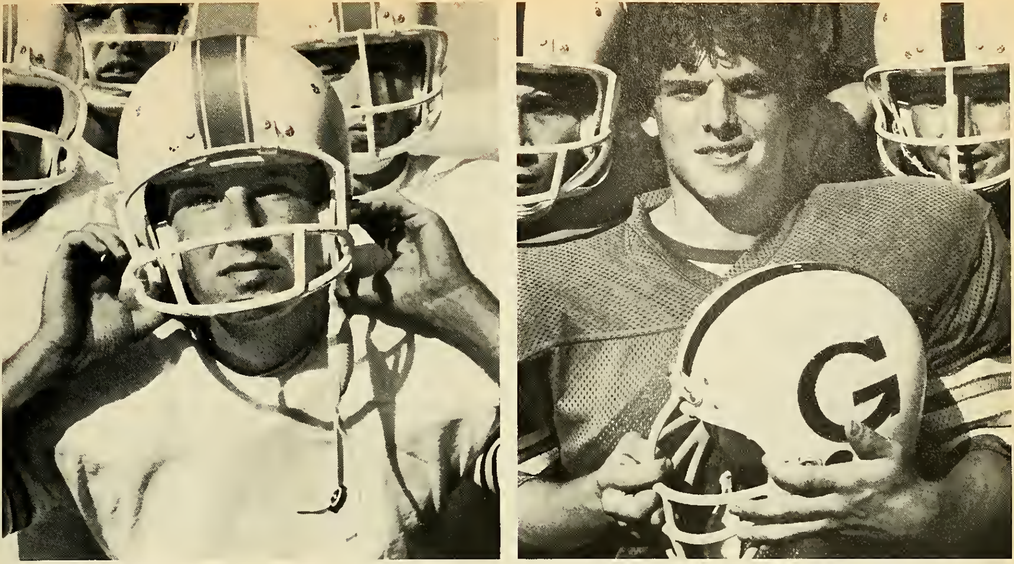
AMNH

Recently, scientific studies have begun to provide an understanding of the biological mechanisms involved in the direct effects of nutrition on fertility. The idea that relative fatness is important for female reproductive ability grew out of the earliest results of my research with Roger Revelle on menarche and adolescent growth. We found that the events of the adolescent growth spurt in boys and girls, and particularly menarche in girls, were each closely related to a critical average body weight. This finding was unexpected for human beings although it was well known that for other mammals, including primates, sexual maturity (defined by vaginal opening or, more precisely, first estrus) is more closely related to body weight than to chronological age.

Our study of the growth patterns of girls in the United States showed that the average weight at menarche, about 103 pounds, did not differ significantly for early- and late-maturing girls, whereas the late-maturing girls were on average taller than those who matured earlier. These results confirmed the many reports in the literature that early maturers have more weight for height than do late maturers.

Even before taking the next step—exploring the meaning of the critical weight for an individual girl—the idea that menarche is associated with a critical weight for a population explained many observations associated with early or late menarche. Observations of earlier menarche are associated with attaining the critical weight more quickly. The most important example is the secular, or long-term, trend to an earlier age of menarche in the United States and Europe of about three or four months per decade in the last one hundred years.

The average age of menarche of United States girls is now 12.6 to 12.8 years. In contrast, a hundred years ago the average age of menarche was about 15.5 to 16. (The medical definition of precocious puberty has changed accordingly: in 1850 to 1870, precocious puberty was defined as 11



# One of these helmets came off the field and off the market when the rules of the game changed.

Not the football rules, but the rules of the legal system under which manufacturers can be sued for damages. In recent years, courts have been inclined to hold a product manufacturer or distributor liable for injuries even when the company had met safety standards or when the injured person was negligent in using the product.

As a result, judgments, settlements and legal costs in liability cases have increased dramatically. Businesses are faced with uncertainty in trying to gauge the extent of their exposure to lawsuit. When these factors outweigh the benefits of making a product, that product will leave the marketplace.

That's what happened to the manufacturer of the helmet on the right. He stopped production of helmets until, as he says, the legal climate changes in the United States. It has happened also to some makers of vaccines, plastic products and machines. Right now, the chemical and pharmaceutical industries are deeply concerned about the potential financial impact of recent court decisions.

As a major group of property and casualty insurance companies, we, too, are concerned about this problem. Our companies provide insurance designed to protect business from financial loss resulting from a lawsuit. This protection normally encourages business to remain in the marketplace. It enables manufacturers to develop new products, to provide more jobs and generally to contribute to our economy.

But the trend in legal judgments threatens all that stability. As lawsuit settlements and awards become higher, insurance companies tend to be more cautious in writing insurance coverage. And they must charge more for it. That in turn causes manufacturers and sellers to raise their prices to cover the increased cost of insurance protection. Which means that consumers pay more for what they buy.

It's frustrating, but not hopeless. Steps can be taken to prevent injuries and to control the rise of liability costs. And that would benefit everyone.

**Here's what we're doing:**

- Helping to develop standards for safer products.
- Advising manufacturers on safety procedures and loss prevention programs.
- Supporting legislation to reduce the enormous legal costs of administering the product liability system.
- Supporting legislation to make the standards of legal liability more definite, more predictable and more equitable.

**Here's what you can do:**

- Seek quality products. Check to see that they meet safety standards where appropriate.
- Use all products as they are meant to be used. Read and follow warning labels and instructions for product usage.
- Get involved! Become aware of proposals to improve fairness in the legal liability system.

**Affordable insurance is our business...and yours.**

This message is presented by the **American Insurance Association,** 85 John Street, New York, New York 10038.

and 12 years of age; at present, it is defined as ages 8 and 9.) The average weight at which menarche was attained in a population, however, was the same a hundred years ago as today. Our explanation of the secular trend, supported by historical data, is that children now are bigger sooner. Therefore girls (considered as a group) more quickly reach 101 to 103 pounds, the average weight at menarche in the United States and many European populations (such as the English, Dutch, and Finnish). According to this hypothesis, the secular trend should end when the weight of children at any given age level (for example, all 12-year-olds) does not differ in successive years owing to the attainment of maximum nutrition and child care. This may now have happened: the average age of menarche of girls in this country is the same today as about thirty years ago for well-nourished girls.

Conversely, a late menarche is associated with body weight increase that is slower prenatally, postnatally, or both, so that the average critical weight is reached at a later age. For example, malnutrition delays menarche; twins have a later menarche than do singletons of the same population because they grow more slowly; and high altitude delays menarche by slowing the rate of weight growth both in utero and after birth. Some of the latest recorded average ages of menarche in the world, 17 and 18 years, are of high-altitude, poorly nourished populations.

The weight dependency of menarche in human beings, as in animals, operates as a compensatory mechanism for both environmental and genetic variation. The result is a reduction in the variability of body size at sexual maturation. Like that of many other animals, human body size at sexual maturation is close to adult size: weight and height at menarche are 85 percent and 96 percent of adult weight and height, respectively. The regulation of female body size has obvious selective advantages for the species since birth weight is correlated with the prepregnancy weight of the mother, and infant survival is correlated with birth weight.

In order to understand how critical weight at menarche operates for the *individual* girl, it is necessary to see how, during the slow, long-term maturation of the reproductive system, the growing body changes not only in size and shape but also in the proportions of the tissues. A fundamental aspect of "growing up" is the change in the relative weight of water, protein, bone, and fat in the body. These adjustments accelerate during the adolescent growth spurt.

Research by others suggested that in mammals changes in metabolic rate and stored fat may be related to sexual maturation. My colleagues and I therefore analyzed the components of body weight—water, lean body mass (which includes the skeleton), and fat—for individual girls. Estimation of body composition showed that the greatest change, by weight, in both early- and late-maturing girls, during the adolescent growth spurt up to menarche, is a 120 percent increase in body fat, from about eleven pounds to twenty-four pounds. Lean body weight, in contrast, increases only about 44 percent. The ratio of lean body weight to fat thus changes from 5:1 at initiation of the spurt to 3:1 at menarche.

Water becomes a lower percentage of the body weight as fat becomes a larger percentage since fat contains little water. At menarche, girls average about 55 percent water and about 24 percent fat. At the attainment of mature height and weight, at 16 to 18 years of age, an average well-nourished young woman in the United States (height 65 inches, weight 125 pounds) is about 52 percent water and 28 percent fat. The completion of height and weight growth coincides with the end of the period of adolescent subfecundity, when the ovary, uterus, and oviducts have also completed their growth. An average United States male is considerably leaner at the completion of growth (at about 18 to 20 years of age), being about 61 percent water and about 14 percent fat.

Reproduction requires energy. A pregnancy requires a total of about 50,000 extra calories, and lactation about 1,000 extra calories a day. In prehistoric times, successful lactation was an absolute necessity for the survival of the infant. The main function of the thirty-five pounds of fat stored on average by both early- and late-maturing girls by age 18 may be to provide easily mobilized energy for reproduction. The 144,000 calories stored at the time of mature reproductive ability would be sufficient for a pregnancy and about three months' lactation. The human brain, it should

# Nobody else makes theirs like ours. So no others are guaranteed for life.

In an industry where quality prevails, doesn't it make you wonder why Zeiss and only Zeiss guarantees its binoculars for a lifetime?

Sound like a high-risk commitment? It isn't at all. It's 134 years of optical leadership, 200 superbly engineered parts, 1800 operations and grueling inspections to insure the highest level of optical and mechanical performance, resistance to climate variations, and complete freedom from internal reflections, ghost images and other disturbing image-deteriorating problems under all lighting conditions. And a meticulous choice of materials. With this background and fail-safe procedure, the odds are in our favor that the workmanship and materials will last as long as what they make.

And what they make is a pair of binoculars that will always transmit more light than any other; focus with incomparable precision; reveal more at dusk and dawn with more color trueness; and offer unparalleled edge-to-edge image quality and resolution.

Until others are made like ours, Zeiss will continue as the only binoculars guaranteed for life.

be noted, grows most rapidly during the last trimester of pregnancy and the first months after birth.

The research on the changes in relative fatness in normal, well-nourished females provided standards to assess weight changes in girls and young women undernourished by injudicious dieting and in patients with the psychogenic disease anorexia nervosa. Our investigation showed that a minimum weight for height, representing about 17 percent fat of body weight, was necessary for menarche, and that a heavier minimum weight for height, representing about 22 percent fat of body weight, was necessary for the maintenance or restoration of regular ovulatory cycles.

We found that the weights at which menstrual cycles cease or resume in young women age 16 and older are about 10 percent heavier than the minimal weights for the same heights observed at menarche. For example, a young girl 63 inches tall should weigh at least 91 pounds before menstrual cycles would be expected to start. In comparison, a 20-year-old amenorrheic woman of the same height will normally have to weigh at least 102 pounds before menstrual cycles can be expected to resume. The heavier postmenarcheal weight reflects the 10 additional pounds of fat added during the period of adolescent subfecundity. (At present, our standards apply only to United States and European females, since different populations have different critical weights at menarche, and researchers do not as yet know whether the different critical weights represent the same critical body composition.)

It is important to note that other factors, such as emotional stress, affect the onset and maintenance of menstrual cycles in human beings. Therefore, menstrual cycles may cease without weight loss and may not resume in some women even though the minimum required weight is attained.

High energy outputs, in addition to low nutritional intake, interact with fatness to affect female menstrual periodicity. Women ballet dancers and athletes who train intensively have a high incidence of amenorrhea. In runners, the incidence is directly related to weekly training mileage. When intensive training begins at an early premenarcheal age, menarche may be delayed until as late as age 19 or 20. Studies of dancers show that menarche may occur after an injury that

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. UNITECH
ALARM-CHRONO
3: 19 09

# SUPER WATCH

## Don't be fooled by the price. This LCD Dual Alarm Chronograph is probably the best as well as most useful watch on the market today.

This watch is in a class by itself. With every conceivable convenience ... unmatched feather-light comfort ... and rugged dependability with matching, trim-slim styling.

And it's priced so low, it makes sense to own as an every-day watch you can wear without worrying or as an extra watch you use only for running or when you're working around the house or for its wake-up alarm and second timekeeping zone when you're traveling.*

What's amazing is that it gives you TWO of everything other watches selling for ten times as much boast of when they have just one. And it includes additional conveniences, like a count-down timer; so, no other watch, at any price, does as much or does it better! And this watch is guaranteed for ONE full year.

**WORLD CLASS ACCURACY:** First and foremost it's guaranteed to be accurate to within seconds a month, three-minutes-a-year. You can be certain the big, easy-to-read display with the hour, minutes and running seconds is right on time—to the second.

Your watch also gives you the day and date at a glance, with no button to push, adjusting automatically for the number of days in any month (including leap year). Then, so you can see easily in the dark or when it's dim, there's a built-in night light.

**3-YEAR BATTERY:** And this is one watch you won't have to worry about for a long, long time. The battery is warranted to last for a full three years.

**TWO-TIMING:** What is more, you get a second timekeeping zone. A convenience you'll really appreciate when you travel or when you're doing business with a firm in a far-away city. Plus a two-note chime you can set to go off on the hour to keep the time from passing you by.

**24-HOUR ALARMS AND PERSONAL REMINDER SYSTEM:** The alarm can be set in an instant for any minute of any hour. The precision of a digital alarm is simply unbeatable. If you want, you can leave this alarm set for the same time every day because there's a SECOND alarm as well. With two alarms you'll be able to schedule your day and stick to your schedule more easily and surely than ever before.

**30-MINUTES AND COUNTING:** In addition, inspired by the Space Center, you also get a 12 hour to one minute count-down timer. Really, a third alarm, it's a lot easier to use if you want to be reminded your time is up or you have to act—when you've promised to call back in half-an-hour, for example, or have to put another quarter in the parking meter. With a count-down timer, you can be sure you won't goof, and you'll know exactly how much time you've got left. (If nothing else, those steaks you like rare and your three-minute eggs will never be over-done again.)

**CHRONOGRAPH SYSTEM:** With 1/100th of a second precision for up to 12 hours, the dual chronograph literally enables you to command time to stand still. With the stopwatch you can time any event in its entirety — from a speech you're preparing to the length of a phone call you're making to the time it takes a passer to set up and throw. (A buzzer sounds when you start or stop the chronograph. A nice feature since it means you won't have to check to see if it's timing.)

You can also measure sections of an event, like the time for the 1/4 or the 1/2 or the times of individual finishers in a race. This is Lap Time. In this mode the chronograph continues timing an event in memory at the same time that it's stopped to give you a reading on a particular segment.

You'll be able to use either of these modes in minutes, find innumerable uses for both in your business and personal life within days.

**SUPER LIGHTWEIGHT:** Even with all these functions, you'll hardly know you're wearing a watch. It's that light and comfortable. Less than one ounce.

The case, which is exceptionally handsome, is made of a high-impact, virtually impervious black plastic. An advance almost as remarkable in its way as those in the microprocessor that controls the watch's functions.

### THE MOST IMPORTANT FEATURE OF ALL

Here's a watch, then, with phenomenal accuracy and totally unique capabilities; a watch that passed every quality-control test with flying colors and stood up to 10 years' of simulated-use tests. And all it costs is the amazing low price of just $29.95!

It just didn't seem possible to us either. But the manufacturer, who's been making components for years for many of the major watch companies, including some of the biggest, best-known names, explained:

"Of course, you'd expect it to sell for 100% more. But, once this new kind of case became available, we knew we could produce a chip (microprocessor) superior to any we made for anyone else, and sell it for far less than you'd expect by assembling the watches ourselves and selling them direct-by-mail, eliminating the middleman's mark-up in both manufacturing and selling."

As proof, in about a year, a major name in the watch world plans to buy this module and offer this same watch through normal retail outlets for at least $60 and maybe more.

### ANOTHER CHOICE

This gave us an idea. What if the same watch was put in a stainless steel case with a stainless steel band. After some figuring the manufacturer said he'd include a deluxe mineral glass crystal, so the watch would be absolutely superb, and all we'd have to charge is just $59.95.

### CALL 800-228-5959

(Nebraska residents call 800-642-8777)
(Numbers in operation 7 days a week, 24 hours a day)

So, that's your choice of the matte black watch or the watch in stainless steel with a stainless bracelet.

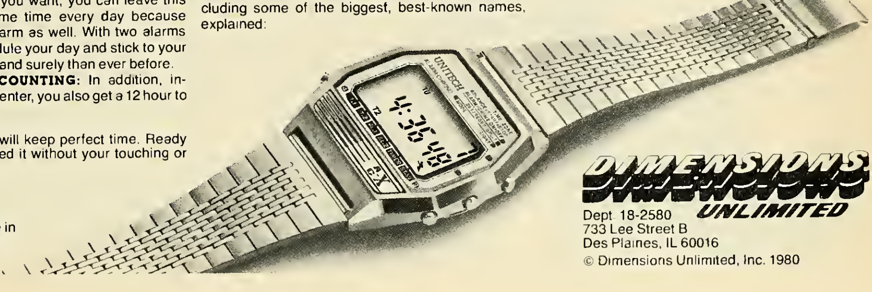
What is more, since you can't get this watch in any store, we'll send it to you to wear for 30 days without risk or obligation. If you're not absolutely satisfied, if the accuracy isn't exactly as we say, if you don't find two timekeeping zones, the two alarms, the dual chronograph, the count-down timer as useful and convenient as you supposed, if people don't praise the look of the watch you're wearing, send it back for a complete refund. No questions asked.

To order with any major credit card, simply call the toll-free number above. But we'd prefer, in this instance, since the price is so much lower than for anything else we sell, that you send us your check to the address below. Just be sure to specify the Black Watch or the Stainless Steel Alarm Chronograph and include the proper amount. (Include $2.50 for shipping and handling and in Illinois the 6% sales tax.)

Either way, you'll be getting a watch as good if not better than any watch in the market today. At a fraction of the usual price. If that isn't class, what is?

---

*Even in a drawer, it will keep perfect time. Ready when you want or need it without your touching or adjusting a thing.



Available in stainless steel

Hormonal changes observed in women amenorrheic because of excessive thinness correlate with the changes in weight and body composition. A return to a prepubertal pattern of hormone secretion is found with the reversion to a prepubertal body composition of lean to fat. The close association between the hormonal secretory pattern and changes in body composition suggests that there is some signal from the central nervous system to the hypothalamus, a part of the brain that controls the eventual release of gonadal hormones.

From an evolutionary view the economical and reasonable hypothesis is that physical ability to reproduce successfully and hypothalamic control of reproduction are synchronized by the central nervous system. Both the absolute and relative amounts of fat are important since the lean body mass and the fat obviously must be in a particular absolute range, as well as a relative range, that is, the individual must be big enough to reproduce. It has recently been found that transformation of androgens to estrogen takes place in human breast and abdominal fat, suggesting that adipose tissue may be a significant extragonadal source of estrogen. Body weight, hence fatness, also influences the direction of estrogen metabolism to the most potent or least potent forms. The high percentage of fat in the mature human female thus may directly influence reproductive ability.

Food intake and ovulation also may be related in a particularly interesting way, as is evident in the phenomenon of "flushing" found in sheep. Flushing is the increase in the rate of twinning resulting from short-term (for example, a week) high-caloric feeding by the ewe before mating. The well-nourished human female, fortunately, does not normally superovulate in response to a high caloric intake. However, some women may be sensitive to a food intake signal. When nutrition was severely restricted during World Wars I and II, a decrease occurred in the rate of human dizygotic twinning (nonidentical twins from two fertilized eggs). There was no change, however, in the rate of monozygotic twinning (identical twins from one fertilized egg). The rate of dizygotic twinning returned to normal after food supplies returned to peacetime levels.

We still have much to learn about the mechanisms involved, both for the individual and for populations. As we have seen, the British historical data on nutrition, growth, age of menarche, birthrate by age of the mother, incidence of sterility, birth interval, and age of menopause, show that slow growth to maturity of women and men due to hard work and disease is correlated with a reproductive span that is shorter and less efficient than that of a well-nourished population. But why is a late menarche in a population usually associated with an earlier menopause, with long lactation intervals, and with higher pregnancy wastage? Are there exceptions in some environments to these associated events? How much is reversible after growth is completed?

One endocrinological explanation for these interactions is suggested by experiments in which my colleagues and I fed animals high-fat and low-fat diets that substituted fat isocalorically for carbohydrates. The animals on a high-fat diet reached sexual maturation significantly earlier and were relatively fatter than the animals on a low-fat diet. The well-nourished human female, particularly on a diet with a high percentage of calories from fat, may have higher estrogen levels, which result in a higher reproductive efficiency than is found in females with less adiposity.

Whatever the mechanisms, the fact that undernourished human beings and animals are less fecund than well-nourished populations can be regarded as an adaptation to reduced food supplies and of ecological advantage. Reduction of fertility as a result of undernutrition and hard living is a less wasteful mechanism than the regulation of overpopulation by mortality. Of course, in the case of humans, there are also social customs—such as a late age of marriage or a taboo on intercourse during lactation—which affect the rate of pregnancy in a particular society.

The Bush people of the Kalahari Desert today demonstrate the type of reproductive pattern found in nineteenth-century Britain. The Bush people are not starved, but their caloric and protein intake fluctuates seasonally and averages significantly less than that of well-nourished people of developed countries. Sociologist Nancy Howell has found that a Bush woman has an average of less than five living births in her whole reproductive span. A well-nourished United

States woman who does not use contraceptives, such as a Hutterite, averages eleven to twelve children, beginning at a later age of marriage.

Former explanations of the relatively small size of the Bush family have included venereal disease and abortion. Strong support for the alternative explanation of a lower level of reproductive ability is found in the changes that take place when Bush women move to trading posts. There, women eat a higher calorie diet; they also no longer expend so much energy in food gathering. Among these migrants, the age of menarche is becoming earlier and the birth interval is shortening; natural fertility therefore is increasing.

If subfecundity was the main reason for the relatively low observed fertility among British working-class couples in the nineteenth century, a reasonable question is, Who at that time was using the many (inefficient) methods of contraception devised during human history? The data suggest that contraception would have been used by females (and males) who were well nourished, hence fully fertile, and whose reproductive ability exceeded their desire for offspring. This would be a small percentage of the population: the relatively well-fed aristocracy, especially those who used wet nurses; the wet nurses themselves, since pregnancy would affect their ability to nurse; and prostitutes, whose aspirations of fertility were zero.

Undernutrition may have been one of the reasons for the relatively low fertility observed in nineteenth-century Britain. Undernutrition, instead of widespread use of folk contraception, may also explain the completed family size of six to seven children found in many developing countries today. If so, the nutrition programs necessary for a vigorous, productive society should be closely integrated with family planning programs for the well-being of the mother, the child, and the society. The research on the direct pathway from nutrition to fertility implies that when couples are well fed, and their potential fertility is high, there is interest in, and receptivity to, the idea of efficient means of contraception.

*Unraveling the evolution and extinction of a large, flightless bird*

**by Joel Cracraft**

On a wintry day in early February 1844, a large crowd assembled at the Royal Institution in London to hear a lecture about some old bird bones recently arrived from New Zealand. As was the custom, the gentlemen were at their attentive best on the main floor, the ladies were in their proper Victorian place high up in the gallery, and the physicist Michael Faraday was prepared to serve tea at the conclusion of the festivities.

That the famous of London's scientific and literary society (Dickens and Carlyle were often in attendance at such functions) would spare the time to learn the latest about bird bones may seem curious, but the lecturer was none other than Prof. Richard Owen, England's premier anatomist and paleontologist. And these were not ordinary bird bones he was to talk about—they were the relics of giant flightless birds that were thought to be, as Owen's wife was to characterize them in her diary, the "only remaining types of a large creation as proper to an early state of the globe."

The intellectual community's keen interest in these birds had its origins five years earlier. In 1839 Owen had stunned his fellow scientists by describing a fragmentary scrap of limb bone, brought to him by a sailor just returned from New Zealand, as having come from a previously unknown form larger than an ostrich. When Owen submitted his paper to the Zoological Society of London, the publication committee protested strongly. After all, how could one reconstruct a giant flightless bird from such a small scrap? And how could such a large bird have escaped the eyes of several generations of New Zealanders? The bone was not fossilized, so if Owen was correct, the living bird surely would have been observed by someone. Finally, however, at Owen's insistence—and at some risk to his reputation—the paper was published, and copies were distributed across New Zealand. Four years later more bones arrived from naturalists in New Zealand, and Owen had the proof he needed. Over the next forty years, he and others described dozens of species representing forms the size of a turkey to those standing taller than an ostrich.

How did these birds, called moas from the Polynesian word for fowl, come to occupy New Zealand? What factors facilitated their evolution, which resulted in remarkable taxonomic and morphological diversity? And why did they become extinct? These and other questions have puzzled scientists for more than a century, but only within the last decade have biologists and anthropologists begun to

Buy a 14K Gold Heart for $5 Until Nov. 26

As part of an advertising test we will send a solid 14K gold floating heart pendant charm to every reader of Natural History who reads and responds to this printed notice before Midnight, Nov. 26, for the sum of $5 plus $1 shipping, handling and insurance. There is no further monetary obligation. [Each heart is composed entirely of solid 14K gold and will be accompanied by our Certificate of Authenticity to that effect.] This advertising test is being placed simultaneously in other publications. If you see it in more than one publication, please let us know, as this information is helpful to us. Should you wish to return your heart you may do so to the address below and receive a full refund. There is a limit of one (1) heart per address, but if your request is made before Nov. 17, you may request a second heart by enclosing an additional $5 plus $1 shipping, handling and insurance. No request will be accepted past the dates noted above; your uncashed check will be returned if postmarked later than those dates. Please enclose this original notice with your request; photocopies will not be accepted. Send to: ABERNATHY & CLOSTHER, LTD., **Gold Advertising Test, Dept. 569-9, Box 1310, Westbury, New York 11590.** (A82490)

furnish some satisfactory answers.

Moas belong to a group of birds known as ratites; included in this group are the rheas of South America, the ostriches of Africa, the extinct elephant birds of Madagascar, the emus and cassowaries of Australia and New Guinea, and the kiwis of New Zealand. Except for the kiwis, all these birds are large, flightless, and look much alike. Many experts, even as recently as fifteen years ago, considered them to be unrelated to one another. These workers hypothesized that each species had its own distinct ancestor, which flew to these far-flung southern landmasses and independently evolved large body size and flightlessness. Not unexpectedly, this hypothesis had special appeal to a scientific community that, at the time, accepted the notion of stable continents and ocean basins.

Then, in the 1960s and 1970s, ornithologists began to reinvestigate the comparative morphology, behavior, and biochemistry of these birds. All the available evidence provided by these studies supports a hypothesis of common ancestry for the ratites and a close relationship between them and the tinamous of South America, a family of grouselike birds capable of flight. Moreover, on the basis of morphological data, biologists have postulated that rheas and the ostriches are each other's closest relatives and that they, in turn, are related to the emus and cassowaries. These four families, furthermore, appear to share an ancestry with the elephant birds, and finally, all five can be related to the kiwis and moas.

This hypothesis of relationships has some important implications, two of which seem to answer the question about the origin of the moas. For example, the hypothesis implies that ratites evolved large body size and became flightless only once, near the beginning of their ancestry. The second implication is that ancestral ratites were rather widespread over a united Southern Hemisphere landmass. When the continents began to break up and drift apart in the middle to late Cretaceous (about 80 to 130 million years ago), progenitors of the modern families were isolated.

In the Cretaceous, a continental mass, which later became New Zealand, lay connected to the Ross Ice Shelf region of West Antarctica. Topologically and geologically distinct from East Antarctica, West Antarctica was apparently united intermittently not only to the New Zealand continental block but also to the southern Andean portion of South America. It can be postulated that at some time in the late Cretaceous an early ratite ancestor was distributed over a common New Zealand-West Antarctica-southern South America landmass. With the northward drift of New Zealand, beginning about eighty million years ago, that ancestor became isolated. A subsequent evolutionary event within the New Zealand continental fragment produced the lineages leading to moas on the one hand and kiwis on the other.

Moa bones are known from natural deposits 600 to 33,000 years old and from sites associated with human activity, all of which are less than 1,000 years old. These remains are now classified into six genera and about thirteen to fifteen species. The genera are characterized by differences in body proportions and in the shape of the head and bill, suggesting that the species of each genus had a distinct method of obtaining food. Within each genus, however, the species are differentiated from one another primarily on the basis of size. This twofold aspect of evolutionary divergence—by shape among genera and by size within each genus—has produced a remarkable radiation in morphological diversity. As an example, the genus *Dinornis* contains four medium (five to six feet tall) to very tall (nine to ten feet) species, all of which have broad, flattened skulls and bills and extremely thin legs for birds their size. The genera *Euryapteryx* and *Pachyornis*, on the other hand, have two species each—one small (three to four feet) and one medium to large (five to seven feet)—and are robust, heavy-boned birds with deep, strong skulls and beaks. The remaining genera, *Megalapteryx*, *Anomalopteryx*, and *Emeus*, consist generally of smaller species (four to five feet tall) with relatively weak bills of varying shape. (Another interesting morphological characteristic of moas is that they are the only group of birds known to have lost all the bones of their wings.)

How can this pattern of species and morphological diversity be explained? The answer to this question probably has two components, one relating to paleogeographic and paleoclimatic changes that took place during the Tertiary and Pleistocene and the other to the ecological interactions that occur among species faced with exploiting similar and restricted resources. As is frequently the case in paleontological

# SPARKLE IN THE COLD!

It's 10° outside . . . Even getting colder. So you bundle up in layers and layers of heavy clothes. First with long underwear . . . then bulky, restrictive thermalwear on top.

Oh, you were warm, all right. Like in a Turkish bath. Because you began to perspire from all your activity. And perspiring in that mountain of clothes is like perspiring in a plastic bag! The perspiration is locked in. So there you are. Wet and miserable.

But now, at last, Damart has solved the problem. Because Damart invented underwear that keeps you *warm, dry and comfortable* no matter how cold it is or how long you stay out. Underwear that's soft and light so you can move easily. Underwear knitted to let the *perspiration evaporate through* so you always stay warm and dry next to your skin.

Damart does this with a new miracle fabric—Thermolactyl. No other underwear does this! You can wear Damart indoors too, and turn your thermostat into the 60's. You'll feel perfectly comfortable and enjoy dramatic savings in home heating costs.

Damart is so comfortable that the Mt. Everest climbing expedition wears it. So does the Chicago Bears Football Club, New England Patriots and Philadelphia Eagles. Our free catalog tells the full Damart Thermolactyl story and displays the whole Damart line for men, women and children, *including tall sizes.* Send for your FREE copy now!

reconstructions, both components can be inferred to have been important in moa evolution, but constructing rigorous tests of these hypotheses may prove impossible.

Biologists have established that new species can arise when populations of previously existing species are fragmented in some manner by climatic or geographic barriers. Once in isolation, these fragmented populations diverge, either rapidly or slowly, to become distinct species. One key to a rapid proliferation of species within a restricted geographic area—called an evolutionary radiation—is the occurrence of cycles of population fragmentation, divergence in isolation and reunion of these newly evolved species, followed by another cycle of fragmentation and isolation. In this way an original species gives rise to two or more new species in isolation; then when barriers are eliminated, some of these species may come to occupy the same area. If new barriers arise, the population of each new species is fragmented and additional species evolve. Diversity can thereby increase rapidly.

We can hypothesize that this model of species evolution provides an explanation for the taxonomic diversity of moas. Throughout the Cretaceous, and especially during the Cenozoic, the New Zealand landmass was constantly changing in surface area and topographic features. As the New Zealand continental plateau drifted slowly northward, islands of various sizes and shapes emerged, became united to form large land areas, and were divided once again by rising sea levels. There are at present only two major islands, North Island and South Island, but a series of islands existed for varying periods of time in the early and middle Cenozoic. And in the Pleistocene, the cyclical changes in sea levels, which were correlated with the waxing and waning of the polar icecaps, repeatedly separated and then joined North Island and South Island. This then is the paleogeographic setting that undoubtedly influenced moa evolution. Given the frequency of geographic isolating events that took place during the last forty or fifty million years, it is not surprising to see high species diversity in a group of birds. What makes the radiation of moas interesting, however, is that it involved taxa of large body size and took place on a relatively small landmass. Within birds, the only comparable situation is that of the now extinct elephant birds of Madagascar, where seven species apparently evolved in isolation. In contrast, the classic examples of island evolutionary radiations, such as the Galápagos finches and the Hawaiian honeycreepers, involved species of small body size.

It will be recalled that when moas first arrived on New Zealand they were already flightless and probably of fairly large body size. Subsequent geographic events facilitating evolutionary diversification contributed to modify this basic body plan. This raises the question, How did numerous species of generally similar body plan coexist in an environment in which the diversity of food resources for large flightless birds appears rather limited? Living ratites, except the kiwis, are omnivorous, and so too probably were the moas. New Zealand did not have an especially high plant species diversity and the small vertebrate fauna available as food for ratites was dapauperate.

Some current ecological research suggests that if two closely related species come to share overlapping distributions, and if food resources are limited, then either one of the species will go extinct or the two species will diverge in those aspects of their morphology, behavior, and ecology that are related to resource utilization. If divergence occurs, the species will be able to coexist. In those situations in which many similar species coexist, the problem of dividing up the available resources becomes more acute, and we would predict marked divergence to evolve, presumably to reduce interspecific competitive pressures.

This ecological theory may explain the divergence in body size and bill shape exhibited by the moas. Differences among genera reflect variation in bill shape and body proportions, whereas differences among species of the same genus primarily reflect variation in size. The species in any one location, therefore, apparently manifested a broad range of morphological and, presumably, ecological diversity. Because the stomach contents of some individual moas have been preserved, we know that they fed on leaves, twigs, and fruits.

The striking diversity in bill shape suggests there was a corresponding variety of feeding methods. Compare, for example, the large species *Pachyornis elephantopus*—even its name characterizes this ponderous six-foot bird—with the slightly smaller *Euryapteryx geranoides*. Both were roughly similar in size and occurred together over

*Light up your life!*

**CHART ROOM SWIVEL LAMP OF GLEAMING SOLID BRASS**

Designed originally for use in ships' chart rooms... now a handsome and handy addition to your home!
Perfect for reading, studying, sewing, crafts, hobbies and all close work

**only $64.00** **Sight-Saver Special 2 for $119.00**

This solid brass lamp is a "sight for sore eyes" in two ways. First, its traditional nautical look and efficient design give it a unique, functional beauty that blends well with every decor. Second, and most importantly, it helps eliminate eye-strain with a four-direction swivel feature that puts the light precisely where it's needed. It mounts on the wall, reaches 25" into the dark and can accommodate a high-wattage bulb. Wonderful in any (or every) room of the house . . . doubly handsome and practical used in pairs to flank a bed or sofa! (Z803585), **$64.00 ea., 2 for $119.00**

OUR GUARANTEE
If you are not completely pleased with your purchase, return it any time for a full, prompt, no-questions-asked refund.

much of South Island. *P. elephantopus* possessed a high, rounded cranium with a long, narrow, pointed bill. Its jaw apparatus was heavily constructed, and the large jaw muscle scars indicate a species capable of crushing or tearing highly resistant foods. On the other hand, *E. geranoides* had a broad, flattened cranium with a short, broad bill rounded at the tip. Although the skull presents an impression of strength, the relatively small jaw muscle scars indicate a more limited ability to crush and tear food. Another species in the same deposits, *Emeus crassus*, was the same size as *Euryapteryx geranoides* but had a jaw mechanism as weak as that found in some much smaller species. This example could be applied to the species assemblage known to occur at any given location.

These observations suggest that the species of moas may have avoided competition for the available food resources because they browsed at different heights in the vegetation and possessed contrasting abilities to harvest foods.

The millions of years of geographic isolation and differentiation, accompanied by the evolution of differences in size and shape, resulted in the presence of approximately fifteen species in geologically recent times. Why then did the moas go extinct, apparently all within the last thousand years?

The answer to the question of moa extinction is complex and has been debated for more than a century by archeologists, biologists, and geologists. The difficulty is that the historical record—whether of natural or archeological deposits—is woefully inadequate. Nevertheless, as more sites are discovered and aged by radiocarbon-dating techniques, our picture of moa history is steadily improving.

The Maori people arrived on New Zealand from eastern Polynesia about a thousand years ago. Archeological evidence reveals that both North and South islands were widely settled by 700 years B.P. Bruce McFadgen, a New Zealand anthropologist, estimates the total population of the colonizers at between 500 and 1,000 individuals, but by the fifteenth century those numbers had grown to somewhere between 10,000 and 100,000.

The first human inhabitants found themselves in a wild and pristine land. A lush forest of mixed podocarp-broadleaf trees covered the subtropical areas of North Island and the west coast of South Island, and an equally dense southern beech forest was distributed widely in mountainous and temperate lowland locales, especially on South Island. These forests made penetration and agricultural exploitation of the island interior extremely difficult and nearly all coastal settlements practiced clearance by fire. McFadgen estimates that after 300 to 500 years of occupation perhaps as much as one-third of the forests had been burned.

The lands and waters of New Zealand offered the Maori colonizers a diversity and abundance of food sources. The ocean and coastal waters had fish, shellfish, and large numbers of the New Zealand fur seal. The forests yielded many kinds of edible plants. There were no native land mammals other than bats, but there were giant birds. One can almost imagine what the first sight of moas must have meant to these colonizers at the end of a journey that had taken them over 1,500 miles of open ocean. And they rapidly took advantage of this readily available food source. Moas were harvested in great numbers. Their bones were broken, probably for the marrow, certainly for their use in making tools, such as fish hooks, and for decorative ornaments. Moa nests were also exploited as a food source, as eggshells are abundant at some sites.

From the frequency of moa bones associated with dated Maori sites, the evidence is fairly clear that large numbers of moas were killed in a short period of time. Hunting of moas was apparently a regional phenomenon, depending upon the local abundance of the birds and other foods. Along the coast, for example, food was gathered primarily from the ocean, and moas were rarely used as a food source. Hunting pressure was more severe on South Island, and this probably reflected the vast differences in climate encountered over the whole of New Zealand. On North Island, as moas and other animals became scarce from overhunting, the Maori shifted from a predominately hunter-gatherer economy to one based on agriculture of the East Polynesian sweet potato and other cultigens. The climate over much of South Island, on the other hand, was too cool to effectively grow many of these plants. Thus, southern Maori populations were forced to rely more on hunting.

Did hunting pressure alone result in the extinction of the moas? This is difficult to say. Certainly, hunting was crucial in many ways. Bones of young birds are frequently found at Maori sites, and the removal of eggs and young would have affected future population numbers much more severely than if the killing had been restricted to adult birds (which may have bred before they were killed). Evidence for a strong effect of hunting is also presented by the large array of other ex-

APERTURE PRIORITY AE

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.

tinct species of birds that are commonly found at Maori sites. These included a giant goose, a flightless duck, an eagle, rails, and a crow; one could also add to this list many of the species that are now very rare on the islands. There can be little question that hunting had an impact on virtually the entire avifauna.

But hunting cannot be the only cause of moa extinction. Surely the firing of the forests, with its consequent destruction of thousands of square miles of habitat, had a devastating effect because most of the species of moas were distributed primarily in the lowlands. Apparently, only a few of the smaller species commonly occupied the mountainous regions. A reasonable assumption is that the restriction of moa populations to small tracts of relict forest greatly increased their chances of random extinction.

The species of *Dinornis, Emeus*, and *Pachyornis* were the first to be exterminated, probably within several hundred years after human colonization. *Euryapteryx* was still commonly found between 600 and 800 years B.P., but was extinct by 300 to 400 years B.P. There is no verified record of survival of any moas after this latter date, but some authorities believe that a small species of *Anomalopteryx* or *Megalapteryx* may have survived in the remote wilderness of the Southern Alps until the eighteenth or nineteenth centuries.

*Joel Cracraft is an associate professor of anatomy at the University of Illinois Medical Center.*

# The Balancing Act of Moose and Wolves

*Stability in a prey population can move from one level of equilibrium to another. But if excessive human exploitation is added to predation pressures, the prey may not recover*

**by Gordon C. Haber**

The moose ranks as one of the most biologically successful of the large northern mammals, having colonized a wide diversity of habitats across both hemispheres and persisting over most of these regions despite sustained exploitation by humans, wolves, and bears. In 1966 I began a long-term wildlife study in Alaska's Denali (Mount McKinley) National Park, in part to learn more about moose behavior and population dynamics in a typical subarctic ecosystem. (The Indians called Mount McKinley, Denali, "The Great One," and the name Denali is still used commonly.) While my emphasis in this research has been directed more at the wolf packs that inhabit the region, the role of the moose as a primary year-round food source for most of the Denali wolves mandates that these two species—and others—be observed as a single interacting unit. Moose are complex, highly tuned creatures largely because of predation pressures, but these same pressures also create a potential for much trickier behavior at the population and system levels than has been recognized until recently.

Like most of Denali's large mammals, moose produce their young in May, the beginning of this region's "biological year." By about the middle of the month, most surviving calves from the previous spring suddenly find their heretofore protective mothers to be extremely aggressive toward them, to the point where the bewildered yearlings must either strike off on their own promptly or be dashed to death by violent attack. Only the yearlings with mothers not pregnant are per-

*With the velvet rubbed from his fully grown antlers, this bull moose appears ready for the rutting period. Beginning in early September, intense sexual activity among adult moose in the Denali region of Alaska lasts about six weeks.*

*During the early rut, one bull approaches another, above, with typical rolling and swaying head motions. When fighting ensues, right, the violent battle often lasts for an hour or more.*

mitted to remain with them. Most of the new calves are born during May. Willow thickets throughout the preferred calving regions yield cows with single calves or twins. My surveys indicate that birth rates generally range from 70 to 125 calves per 100 mature cows.

Wolves and grizzly bears combined normally take a heavy toll of calves during the first month or two following birth, even though a cow moose in good condition defends her young with a ferocity seen in few other northern mammals. Young calves are also subject to heavy nonpredator losses, for example, due to wind chill, drownings during river crossings, and other accidents. Nonetheless, since the annual loss of older moose does not normally exceed about 15 percent of their spring total, only a relative few of the calves that are born need survive for the population to remain stable. It is almost as if the rest are "programmed" to be eaten, insuring sufficient energy transfer into higher trophic levels to support the system's major predators and scavengers.

Apparently more than maternal defense is necessary to guarantee that even a small percentage of calves survives early predation. One of the most important antipredator responses that moose have evolved is the synchronization of births each spring. The short, four- to five-day span during which most calves are born amounts to a "pulse" that may saturate the predators, at least temporarily. During the actual birth process, and sometimes for a few hours afterward, a cow cannot fully defend her one or two calves or herself; with dozens of moose births occurring in close sequence, it is unlikely that wolves and bears could kill and consume as many victims as might be possible were births staggered over a longer time interval.

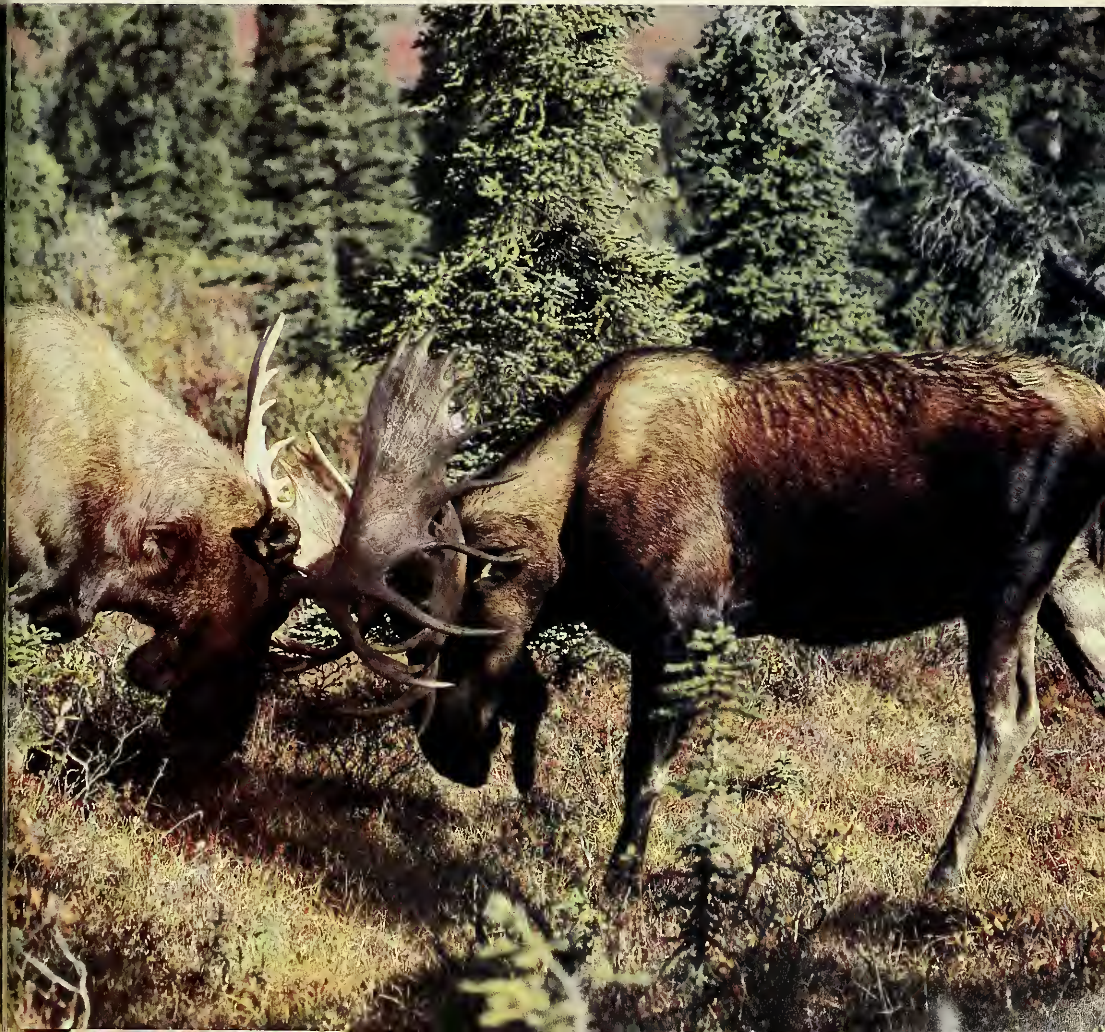
For moose calves that overcome the many early obstacles to survival, still other problems await. The most important of these is shared by all living organisms at arctic and subarctic latitudes: a need to produce biomass rapidly, prior to another winter only three to four months away. Intense solar radiation and long day-length (peaking to about twenty-two hours on June 21) provide major energetic compensation for the brevity of summer, but still one senses an almost urgent race by creatures large and small to develop and prepare. Soon after the Denali tundra fully greens in the first or second week of June, calves are already quite mobile, and nearly weaned, they and their mothers browse lush willow shoots, aspen leaves, and other vegetation for long hours throughout the range. Growth is spectacular. At birth a calf weighs about 30 pounds, a few weeks later perhaps 60 to 70 pounds, and by the end of August approximately 150 to 200 pounds. This compares with late August adult weights on the order of 800 pounds for cows and 1,000 pounds for bulls.

Major changes become evident among the adults as well. Individuals of both sexes begin to develop a dark, shiny coat of guard hairs, replacing their now ragged winter pelage, and body fat reserves are replenished. Perhaps most dramatic is the reappearance in bulls of antlers, which are shed usually by December or January. Six to eight inches of new antler growth can be seen in some bulls by late April, and two to three feet in most mature bulls by July or early August. Antlers are a form of bone, nourished during growth by a characteristic soft covering of skin and blood vessels known as "velvet."

Dark, crisp nights return to Denali by early August. Before the end of the month the hills have been dusted with one or two light snowfalls and the tundra has started to redden slightly. Fall begins in an almost subtle way, but by the end of the first or second week of September, colors explode to a spectacular peak everywhere and the tundra seems ablaze. Coinciding closely with this dramatic seasonal change is an equally dramatic change in moose behavior. This marks the onset of the rut, a period of about a month and a half during which almost every adult in the population becomes involved in intense sexual and breeding activity. To me this is the most interesting phase of the moose population's annual cycle; the willow thickets and spruce patches come alive with action as moose begin to appear in substantially larger numbers than at any other time of the year. By late August many bulls have partially rubbed the velvet from their fully grown antlers; virtually all will be in handsome, polished form a week or two later.

Bulls can now be seen moving about everywhere, challenging each other at first by thrashing their antlers in willow brush, then more and more frequently during light sparring matches. Soon adults of both sexes begin congregating in the same areas, bulls pursuing the cows. Many of the cows are drawn by assorted vocal and olfactory enticements offered by the bulls. Rutting behavior itself is important in this regard: a mature bull thoroughly paws up an area of ground, urinates and ejaculates repeatedly over the spot, and then paws it up again, often continuing this behavior for an hour or more. On numerous occasions I have watched an adult cow a half mile or more away come running and squealing to the resultant wallow as if half crazed, then roll excitedly in it over and over again.

Within a week or two many bulls have assembled harems through such behavior, and by the end of September it is not uncommon to see ten to twenty cows with a single large bull. Often two or more groups form almost adjacent to each other; there are several locations in Denali where each fall as many as fifty to a hundred moose gather in an area of less than five square miles. It is a busy time for the largest, dominant bulls, for they



constantly shepherd their cows and must meet continuing challenges from bulls without cows. While aggression at this time seems to build to higher levels of intensity among the bulls, there are also frequent hoof-lashing battles between cows, suggesting that many of them compete for a bull's attention even after secured within a harem.

When a cowless bull approaches a harem he may remain near the periphery for a few hours or a day or two, but then comes the inevitable confrontation. A typical threat sequence by the bull in possession usually suffices if he is the larger of the two: he thrashes his antlers in brush, then begins walking steadily toward the intruder while rocking his head and antlers slowly and rhythmically in a side-to-side arc, issuing low coughing grunts, and flicking his tongue back and forth over his lips. If this does not convey his message adequately, the bull in possession may bolt for the other bull in lightninglike, ten- to fifteen-foot leaps. This action usually convinces the intruder to try his luck with another harem. In cases where the challenging bull is about the same size or larger, a violent battle often follows the threat displays. This is an awesome spectacle, with the two huge beasts repeatedly crashing into each other, often for an hour or more. Commonly, such battles end with both bulls flattened in total exhaustion amidst hundreds of square yards of torn-up ground and uprooted brush and small trees.

The intense rutting competition helps insure that prime bulls do most of the breeding; however, the high energy costs render many of them more vulnerable to predators and other mortality agents. During the rut practically every mature bull is drenched in sweat from the almost constant activity; and since bulls spend relatively little time eating, their substantially depleted body fat reserves cannot be fully rebuilt before winter. This may lead to heavier adult bull (versus cow) losses during the ensuing winter, but the difference is evident even before the rutting period ends. Some bulls are killed outright in the thunderous battles over harems. More commonly, wolves and grizzly bears deal the final blow. My observations indicate that these predators learn the best locations for moose rutting activities and hence encounter weakened bulls more often than would be expected on the basis of chance alone—similar to what occurs during the spring calving period. (Moose in the Denali region focus their calving and rutting activities in different areas, but in each case these appear to have remained traditional for many decades.) If a wolf pack or a bear arrives just after two bulls have fought to exhaustion, a double kill becomes very likely. I observed this result in five instances during my fall moose surveys.

The tundra turns brown by late September, and shortly afterward the first snowfalls have crept down the mountainsides to the valley floors. Mating activity reaches a peak at about this time, then during the next few weeks social calm begins to return as individuals disperse from the rutting groups. Now the task is basic and straightforward for all sex and age classes: survive five to six months of severe cold, deep snows, fewer opportunities to find adequate browse (which itself is of lower nutritive value than in the summer), and continued pressure from wolves.

The physical condition of virtually every moose in the population deteriorates during the winter, but the slide is much steeper and the odds of surviving until spring are much lower for some, especially for individuals already at a disadvantage because of age, injury, lower fat reserves, or other debilitating factors. Surprisingly though, any calf that has managed to stay alive through the fall apparently enjoys good odds of surviving its first winter. The sex and age data I secured in my annual population surveys indicate that about 60 to 90 percent of the calves that die between birth and sixteen months of age die within the first four months, and most of these deaths occur during the first month and a half. In short, calves still alive when winter begins have already successfully endured much testing, and no doubt most were born in good condition to the strongest and most experienced mothers.

As winter progresses and the snow deepens, developing one or more crusts, moose are forced to expend larger amounts of energy in search of forage that is increasingly difficult to find. Wolves begin to enjoy better hunting success, killing 8 to 9 percent of the moose they encounter in a very severe (deep snow) winter, compared to only about 2 to 3 percent in a mild winter and 5 to 6 percent in an average winter. Moose deaths from nonpredatory factors also increase; in certain years wolves feed heavily on these winter kills, which reduces the number of live animals they kill. Winter can also exert residual impacts on the moose population, for example, through greater nutritional stress in pregnant females. Spring birth rates in Denali are approximately halved after a severe winter.

One of the major ways in which moose minimize such impacts is to migrate. Moose migrations in Denali rarely exceed fifteen miles or an elevation change of 1,000 feet, but when a deep-snow winter hits (as in 1970/71, which was a record for this region), this degree of shifting is sufficient to remove the population from ranges where normal movements and foraging activities can become extremely difficult. The timing and extent of each winter's migration appears to be keyed to average snow depths on the summer ranges. If there is less than one and a half to two feet of snow on these ranges, little or no migration occurs. As depths begin to exceed this threshold, about one-third to one-half of the population moves, and by the

*A bull moose, left, checks a cow's sexual receptivity by smelling her. Five cows, below, flock around the large bull, which has collected them as part of his harem during the rut.*

*A cow, above, nurses her twin calves at the edge of a pond. Weighing about 30 pounds at birth in the spring, the calves grow rapidly. By the end of August they will weigh between 150 to 200 pounds.*

time the average reaches three to four feet, essentially all have left for the winter ranges.

Moose that have migrated are normally able to return to the summer ranges by late April or early May, prior to calving two to three weeks later. Many of the pregnant cows bear their calves in very specific and traditional areas within the summer ranges; one cow that I could identify produced her calves within 100 yards of the same location for at least three years during my study. Not surprisingly, wolves traditionally produce their young in these same areas, using nursery dens at least several decades old.

The lingering deep snow of a severe winter may prevent most moose from returning to the usual calving areas before mid to late May, leading to an important change by the wolves too. This happened in spring 1971, and the result for the moose was a form of compensatory relief from predation. I observed the wolves closely while they scouted the major calving areas in late April and early May 1971, cleaning out established dens and hunting near each for several days, but there were few contacts with moose. The pack finally departed on May 10 and ended up committing itself to a den in another area, closer to an active caribou migration route. Over the next two weeks most of the moose were able to return to their usual calving areas, where cows produced young at about half the rate seen in other years (the low birth rate was predictable because of the impact of the preceding record winter on pregnant cows). Yet there was actually a higher spring to fall rate of calf survival than in summers following winters of average or even mild severity. The higher summer 1971 survival rate could be attributed in part to the likelihood that the severe winter prevented many weak, inexperienced cows from bearing calves. But the wolf denning shift also had much to do with this by, in effect, exposing moose calves to far less wolf hunting than in other summers. Apparently, the lingering deep snow and delayed moose return influenced grizzly bears in some similar manner for I noted less hunting in the calving area by this predator as well.

Perhaps the most significant observation to be made about moose in Denali relates to the long-term status of the population. For the past fifteen years and probably for at least forty to fifty, the total number of moose has remained relatively stable despite substantial predation by wolves and bears and much variation in levels of winter severity. The best moose habitat and highest concentrations of moose are found within the 600-square-mile territory of one wolf pack in particular, and predictably, moose

are used heavily by this pack on a year-round basis. Mountain sheep and to a lesser extent caribou are supplementary food items. Moose distribution is patchy (nonrandom) and moose migrate seasonally from one portion of the territory to another, yet based on population surveys undertaken by myself and National Park Service biologists, the territory-wide density (number of moose per 600 square miles) has fluctuated from only about 0.7 to 1.4 moose per square mile. It might be tempting to relate this stability to habitat factors, given the slow rate of successional change seen here (typical of subarctic ecosystems) and the virtual absence of fire disruption. Nevertheless, we know that this population enjoys a high reproductive rate and that in general the individuals are in excellent physical condition, contrary to what is observed for most ungulate species that

*Followed by her calves, a cow chases a yearling from the area. Until the spring calving season, female moose are protective toward their young of the previous year, but now their attention must focus on the newborn offspring.*

reach the maximum carrying capacity of their habitats and are directly limited by food supply. Furthermore, despite some predictable localized overbrowsing, the Denali population does not appear to be suffering any widespread shortage of food vegetation.

I recognized from the outset that it would be simplistic to assume that only one or a few factors were responsible for the observed population stability, although it seemed likely that predation played a central role. To examine this question in detail, my colleagues at the University of British Columbia and I decided to use a systems approach, in which we considered several hundred interacting predator, prey, habitat, and environmental variables jointly. This meant we would need some sophisticated bookkeeping, hence we began by organizing the many bits and pieces of field data into a computer simulation model. We were then able to integrate all of the variables into only two basic components of system change: moose net production (births minus nonpredator losses) and losses due to predation, and to consider these as a function of prey (moose) density. Next we translated the results of this analysis into a simple graphical model, known as a recruitment curve, which showed variations in the moose population's net annual increment (the difference between the production and loss components) over a wide range of moose densities.

This indicated that increments are positive at moderate moose densities (net production exceeds predation losses), but that they decrease to negative values at both high and low densities. At densities where a positive/negative change occurs the increment is equal to zero, and hence there is a potential equilibrium. We identified three possible equilibria: one within the range of densities observed in Denali over recent years, another at a much lower density, and a third between these two but closer to the lower one. Both the upper and middle equilibria appear to be generated in about the same way. Moose net production drops sharply at each of these densities, but predation losses do not decline in a corresponding way; thus pre-

*Ears back and hairs bristling, a cow charges through a tundra pond toward the photographer. Sensing a threat to her calf, the enraged mother can be very dangerous.*

dation exerts a much greater impact, and in each case a point is reached where it completely removes and then exceeds the equivalence of annual net production. The downturn in net production at high density is probably due to greater resource competition, leading to fewer births and more nonpredator deaths. At the middle equilibrium this results from a sharp drop in births due to the much smaller adult population (that is, fewer cows). The lowest of the three equilibria appears to exist because of a learning-related phenomenon referred to as "switching." In a multi-prey system a predator such as the wolf searches much less for a particular prey type when it becomes so scarce that it is difficult to find. This allows the prey to begin an increase, whereupon the predator is again able to hunt it to advantage, until depressing it to the switching-off point once more, and so forth.

Under natural circumstances a subarctic moose population subjected to wolf predation could be expected to fluctuate about the upper equilibrium for a long period, probably for decades at least. As random events pushed the population below this equilibrium into the density range where increments are positive, it would simply increase again. On the other hand, if pushed somewhat above the equilibrium (for example, by immigration), the negative increments corresponding to this density range would produce a population decrease. In other words, the population is anything but delicately balanced at a stable size. It fluctuates considerably, but the important point is that it can absorb much stress and still continue to fluctuate about the *same* density.

I observed a dramatic illustration of this resilience during my fieldwork in Denali. Within a period of only six years the region experienced a virtually complete spectrum of winter variability, based on the existing fifty years of weather data—the most severe winter ever recorded (1970/71), a second severe winter (1971/72), one of the mildest (1969/70), and several average winters. Winter conditions can exert a variety of direct and indirect impacts on moose birth and death rates, thereby influencing total numbers, yet there has been no major shift in the equilibrium density about which this population fluctuates. Perhaps most impressive of all, my surveys in fall 1970 and 1971—before and after the very severe winter of 1970/71—indicated there had been a net decrease of only 8 to 10 percent in the number of moose present.

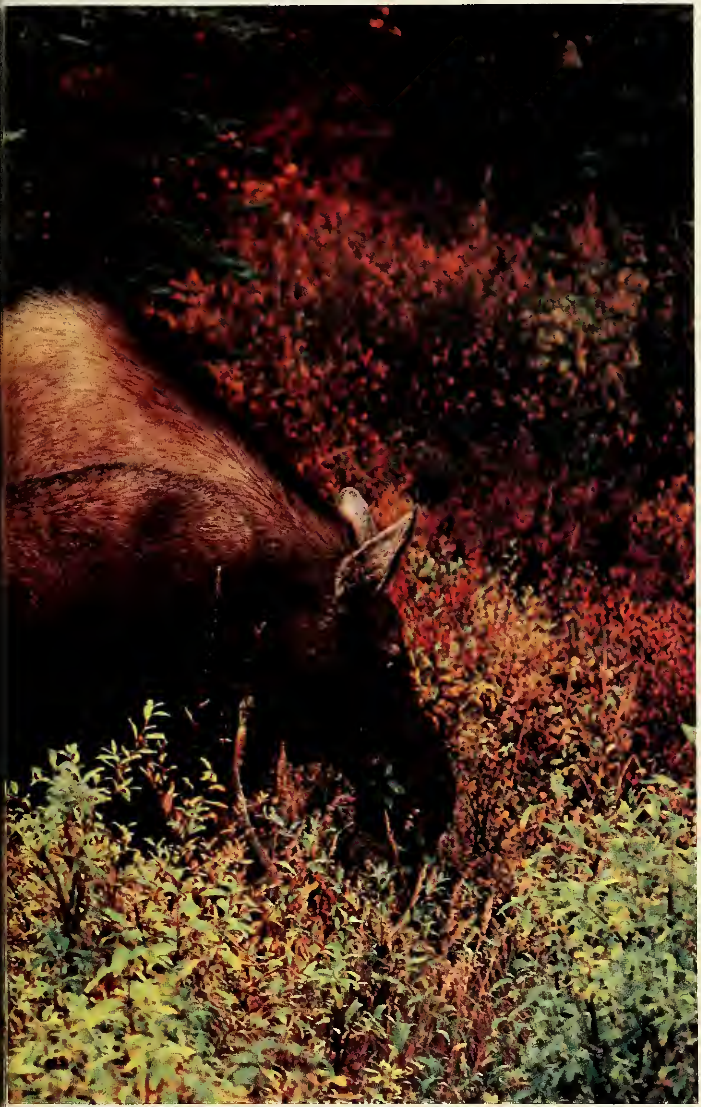
Suppose, however, that the population is subjected to a series of impacts even greater than what has been observed to date, so that it eventually decreases to a density just below the middle equilibrium. Since the combination of lower net production and proportionately heavier predation below this threshold results in negative net annual increments, the population begins a rapid decline that continues even after the initial disturbing agent is removed. With no human intervention (predator control, for example), the decline would deepen until finally abated at a very low equilibrium by

*A spike bull and a cow browse amidst the colorful foliage of mid-September. The bull may be a yearling of the female, which tolerates his presence because she did not bear calves in the spring.*

predator switching. Even in a multi-prey system it might then take twenty to thirty years for the wolves to emigrate or starve to the point where recovery could begin.

This sequence could be triggered by emigration, heavy mortality, and/or reduced natality associated with a natural disturbance, such as a major flood or fire, or perhaps a winter much harsher than 1970/71. Most ecosystems, however, have been resilient to all but the uncommonly severe natural disturbances; were this not the case, the subarctic mountains and tundra would have plunged into biological disarray and scarcity centuries ago.

A more likely trigger in today's North is excessive moose hunting by humans, an impact that we were able to simulate easily in our model. The mechanisms revealed to us in this analysis turned out to be much more subtle than I had expected. Hunting removes a portion of each year's net increment from the moose population, but most important we found that this leads to two equilibrium changes: the upper equilibrium shifts to a lower density and the middle equilibrium shifts to a higher density. As a result, the moose population begins to fluctuate over a lower range of densities and within narrower constraints. Moreover, since increments are negative below the middle equilibrium and this now occurs at a higher density, the odds of an irreversible decline are increased. This means that the same above-average winter that earlier caused only a minor decrease in numbers now could easily lead to a major decline, although it is important to emphasize that such a decline would be expected only when the population is subjected to excessive hunting, specifically an annual rate greater than 6 to 7 percent, according to our analysis. Furthermore, to sustain this harvest the population would first have to be reduced to 60 to 70 percent of its upper equilibrium density, to the level corresponding to maximum net production (at the upper equilibrium net production is lower and just equals the predation loss).



The foregoing multiple equilibria pattern is not unique to moose–wolf systems. Ecologists have found that a wide variety of natural systems are capable of "flipping" abruptly between different stability regions—some regularly, others only when heavily stressed. This phenomenon appears to extend to many physical, socioeconomic, and human behavior systems as well, and to better describe it, mathematicians have even developed a new language, referred to as catastrophe theory.

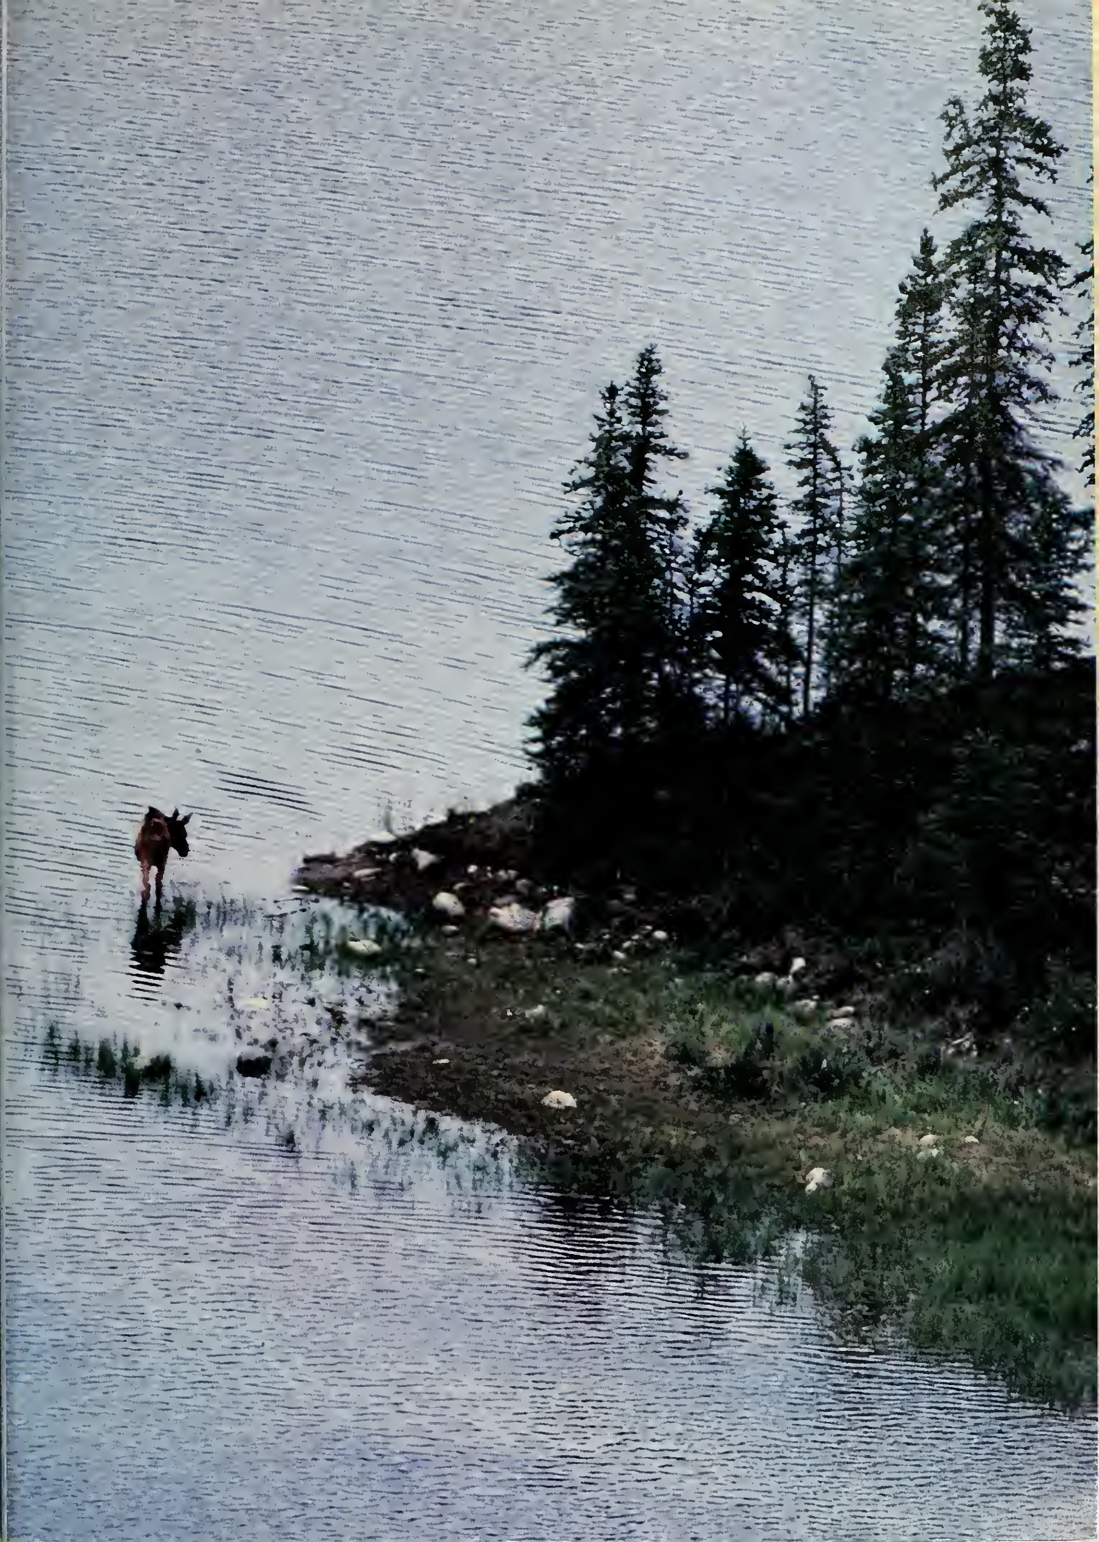
The multiple equilibria/catastrophe theory viewpoint suggests that moose and wolves interact much the same way as, for example, do the parts of a suspension bridge. A wolf pack, its prey, habitat, and assorted environmental factors jointly compose a system; the interconnected beams, supports, and cables of a bridge also compose a system. Normally the bridge is in a horizontal position, at an upper equilibrium, but add weight in the center and it begins to sag a little. Add a bit more weight and the bridge sags a little more, in a manner roughly proportionate to the additional weight. Then remove all the weights and it returns to its previous position. Now add the same weight increments again, but this time many more of them. A threshold will be reached—analogous to the moose population's middle equilibrium—beyond which the addition of just a bit more weight results in a proportionately much greater system change: the bridge suddenly buckles to a completely different position, analogous to the moose population's lower equilibrium. No longer is it possible to restore the bridge to its original position by simply removing the weights. Originally, neither the moose–wolf system nor the bridge was so delicately balanced that it could sustain no additional stress at all. The moose population continued to fluctuate about the same equilibrium even though subjected to the extra "load" of variable winters and some hunting by humans (that is, 6 to 7 percent). Likewise the bridge was resilient to extra stress, flexing somewhat under each additional bit of load, yet still maintaining about the same position. But once a critical threshold was exceeded, both systems shifted catastrophically to another stability region centered on a completely different equilibrium.

The apparent functional similarity that the multiple equilibria/catastrophe viewpoint reveals for a wide variety of systems suggests that they can be understood more easily than we have assumed. In other words, we may not need to reinvent the wheel each time we seek to determine why nature behaves as observed. The same conceptual framework might suffice whether the system we are attempting to understand comprises moose and wolves, mice and owls, or cables, beams, and supports. On the other hand, their characteristic discontinuities and abrupt changes require that much caution be exercised when and where we choose to exploit these systems. Moose can be harvested from a moose–wolf system at an annual rate of about 6 to 7 percent, but if the rate is increased by only a few percentage points, moose numbers may suddenly begin a decline to such low levels that the sustainable yield decreases to almost nothing and controversial predator-control measures are then demanded. Caution is also needed in harvesting other ungulates inhabiting the region. If the wolves utilize a second prey species, such as sheep, as an important food supplement and this population is overharvested to an unusually low level, there will almost certainly be more predation on the moose, leading to an equilibrium shift similar to what was described earlier and hence less resilience to both natural and human disturbances.

Nor does the potential for trickery end even here. An imbalanced adult sex ratio appears to be characteristic of most subarctic moose populations under natural conditions. Within the Denali wolf pack territories that I monitored, the ratio ranged from about 35 to 75 adult bull moose per 100 adult cows. In areas where exploitation is permitted and takes the form of bull-only harvests, ratios as low as 5 to 10 bulls per 100 cows have been recorded. Various studies have shown that such abnormally low ratios do not necessarily lead to reduced pregnancy rates. However, we know very little about the possibility of other impacts on recruitment. For example, with so few bulls it probably takes longer for the same number of cows to be inseminated during the fall rut, which could mean less of a birth pulse in the spring. If births are staggered over a longer time interval, there could well be less predator saturation and, consequently, higher mortality of young calves. Moreover, later births as a result of delayed breeding might mean that many calves enter their first winter at a survival disadvantage, because of less opportunity to develop physically beforehand. A difference of even a week or two could be critical in this regard, given the rapid rate at which early growth normally occurs and its close synchronization with the short interval of high productivity in browse vegetation each summer.

Moose are an important resource to human users throughout the North, especially in Alaska, but over the past ten to fifteen years subsistence and sport-hunting demands have increased to the point where serious population declines have occurred in at least several large regions. When this happens, both the resource and its users lose in a variety of ways. From a strictly biological viewpoint clearly some exploitation is acceptable. The challenge that remains is to apply our growing knowledge about moose behavior and interactions at the system level to help insure that exploitation does not exceed critical limits. □

*Calves may wander some distance from their mothers at times. In the Denali region, 60 to 90 percent of the calves that die between birth and sixteen months of age perish within the first four months.*



# The Versatile Opium Poppy

*Nonnarcotic byproducts of this cash crop are traditionally important resources for Turkish villagers*

**Text and photographs by**
**Jacques Bordaz and Louise Alpers Bordaz**

Opium and opium derivatives have been valued since antiquity for their therapeutic properties. Unfortunately, these same substances are a major threat to the individual and society because they can induce highly destructive psychic and physical dependencies. During the past ten years, our archeological fieldwork in an opium-producing region of south-central Turkey exposed us directly to an intricate problem that has occupied both international agencies and individual states throughout the twentieth century; that is, insuring an adequate supply of opium for medicinal purposes while preventing the illicit production of, and trade in, opiates that ultimately lead to drug abuse. Our life during the excavation seasons in Gölkaşı village on Lake Beyşehir also introduced us, unexpectedly, to the generally unknown but economically important utilization of the poppy plant for many purposes other than the extraction of opium.

Until 1971, our observations of opium poppy exploitation in Gölkaşı had only been minimal. The object of our archeological research was the site of Erbaba, an early sixth millennium B.C. Neolithic settlement, and our supplemental investigations into the traditional subsistence patterns of the present-day farmers had concentrated on the food plants excavated there—wheat, barley, lentils, and peas. But with the total ban on opium poppy cultivation imposed by the Turkish government on June 29, 1971, we were made acutely aware of this crop by the villagers whose lives we shared during the summer. During these past years, we have witnessed the disruption created by the ban and the impact of its repeal in 1974, and have explored the many facets of the controversial poppy.

To the village cultivator, the injunction against the annual planting of the opium poppy represented the loss of a profitable cash crop. Worldwide pharmaceutical needs had long provided a reliable market for Turkish opium. Furthermore, since the poppy's sowing and harvesting seasons generally precede those of grains, the Gölkaşı farmer had been free to grow these foodstuffs central to the local diet.

A member of the diverse and decorative Papaveraceae family, the opium poppy, which probably originated in the Mediterranean or Southwest Asia, is classified botanically as *Papaver somniferum Linnaeus.* In Turkish this plant is *haşhaş* (pronounced "hash-hash"), not to be confused with *haşiş* ("hashish"), a preparation based on hemp, *Cannabis sativa Linnaeus.* The common red poppy, sometimes referred to as the Flanders or American Legion poppy, is also a species of the *Papaver* genus (*P. rhoeas*) but does not produce opium. Opium, *afyon* in Turkish, is a juice secreted by the maturing *P. somniferum L.* Although concentrated in the capsule, or seedpod, of the plant, this liquid also occurs to a lesser degree within the stalks and the leaves.

Prior to the 1971 ban, the villagers of Gölkaşı had harvested their opium according to a technique widespread in traditional cultures and already documented in the writings of Greek and Roman naturalists. This procedure involved incising the capsule in order to free the trapped secretion. In cold temperate climates, like that of south-central Turkey, the opium poppy is generally planted in the au-

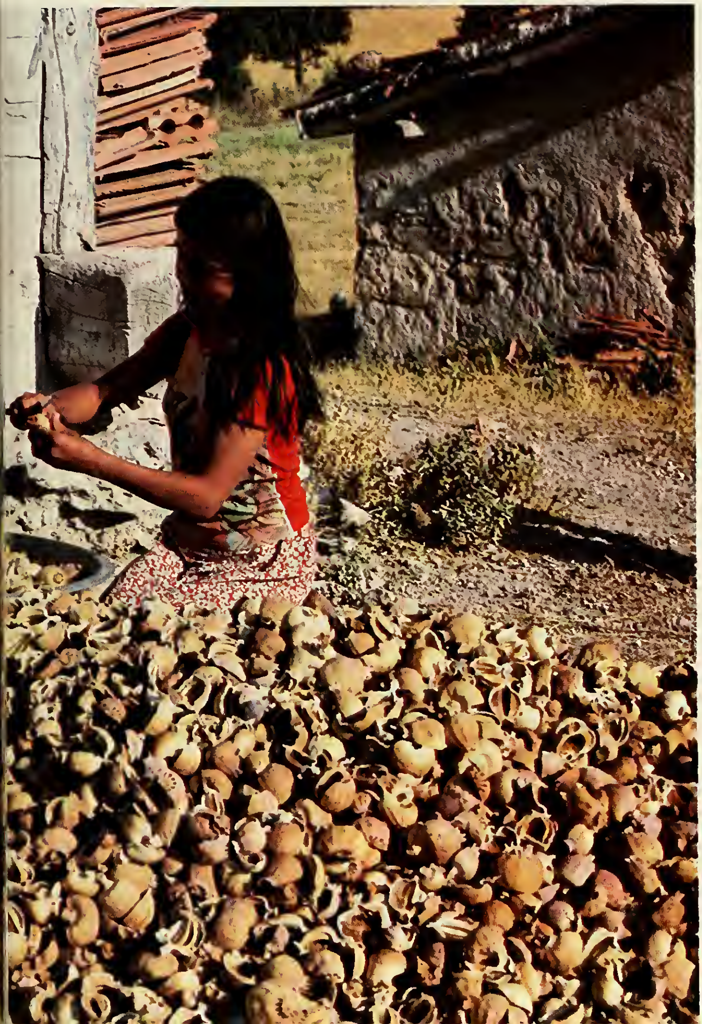
*An opium poppy plant, above, bears buds alongside the maturing seed capsules, from which the flower petals have already fallen. When mature, the dry capsules are collected and split, right.*

tumn. In Gölkaşı, situated at a height of 3,600 feet within a broad basin of the western Taurus Mountains, the spring flowering takes place by late May or early June. The multicolored fields are in bloom for only four to five days, and some two weeks later the plants have ripened sufficiently for the ancient lancing process. In this method, practiced until the ban, several disconnected horizontal incisions were made around the circumference of the capsule. The juice from the capsule proper, in conjunction with that drawn upward by capillary action from the stem and leaves, oozed out onto the surface along the slits and was left to dry for approximately eight to fourteen hours. This raw opium was then scraped off and, when sufficiently coagulated, formed into balls or cakes destined for the Turkish Soil Products Office. The poppy plant, its continued life assured by the cautious, discontinuous incision of the capsule, remained in the field until full maturation.

Although efficient, the incision method involved security risks, since the raw opium collected in the harvest was a potentially harmful drug and also the source of other derivative narcotics. Recognizing the dangers of an illicit traffic in this commodity, the Turkish government had gradually reduced the number of opium-producing provinces, from forty-two out of sixty-seven in 1940 to seven by 1970. The total moratorium in 1971 represented an even more drastic action, one strongly encouraged by the United States. Nevertheless, after several years of successful enforcement, the ban was repealed on July 1, 1974.

The decision to reinstate cultivation of the opium poppy permitted Turkey to participate once more in the lucrative international pharmaceutical market, which had expanded as a result of increasing world health care and was suffering a shortage of opiates during the ban. Despite attempts in the past thirty years to synthesize equivalent drugs, modern medicine still relies almost exclusively on natural products of the opium poppy for the treatment of certain widespread problems. Codeine, a highly effective cough suppressant and analgesic, is one of the most common medications. Present in opium in small amounts, this alkaloid is today primarily extracted in a secondary process from the main opium alkaloid, morphine. Of the morphine employed by the pharmaceutical industry, more than 90 percent is at present transformed into codeine. The use of morphine proper, a potent pain killer and sedative, has been curtailed in recent years because it is intensely habit forming, and heroin, a morphine derivative, has actually been outlawed in most countries because of its even more dangerous addictive properties. Raw opium, now completely supplanted as a therapeutic drug, was used extensively before methods of extracting its alkaloids were developed during the nineteenth century. Enduring quasi-medical uses of opium, documented as early as classical times, are now held responsible for the long history of abuse by eating, infusions, and smoking that marked opium as the object of the earliest international campaigns for drug control—by the Shanghai Opium Commission in 1909 and The Hague Convention in 1912.

In the autumn of 1974, the Gölkası cultivators and their compatriots in the seven authorized provinces planted the opium poppy once again in preparation for the 1975 crop. Harvests from this time on, however, were to differ in an important way from the ancient practices previously employed. The Turkish government, in cooperation with the United Nations Division of Narcotic Drugs, had resolved to eliminate collection by incision and introduce in its place the "poppy straw" process. Developed in 1926 by the Hungarian Janos von Kabay and adopted thereafter in Eastern Europe, this method bypasses the opium stage entirely and derives morphine directly from the dried plant. Forbidden to lance the capsules, the farmers allow the poppy to mature fully in the field. Harvesting now consists of snapping off whole dry capsules near the top of the stems and removing the seeds before selling the capsules to the Turkish Soil Products Office. Seed collection is restricted to longitudinal splitting designed to provide proof that no horizontal scoring for the purpose of opium retrieval has taken place. Since alkaloid extraction from dried capsules is a complex industrial procedure, the poppy straw process itself constitutes a system of control. Supplementary security measures were also instituted in 1974, including compulsory licensing, limitation of crop size per cultivator, and extensive surveillance by law enforcement agencies.



The Gölkaşı villagers readily accepted these new techniques and restrictions. Eliminating opium production did not affect them adversely since the use of opium in folk remedies had disappeared with the proliferation of well-stocked modern pharmacies in the region. Nor had they indulged in opium for pleasure. In Gölkaşı, as elsewhere in Turkey, strict mores against opium consumption for other than therapeutic reasons have long characterized the rural society. Furthermore, the poppy straw method was immediately recognized as a far less tedious and time-consuming alternative to the lancing practice.

One unexpected advantage of the poppy straw process did not become apparent until the first harvest in 1975. Since the seed yield from unincised capsules is markedly greater, the cultivators profited additionally from the increase in this resource. Although we had in previous years often enjoyed the delicate, nutty taste of the seeds—freshly removed from their capsules or mixed with boiled wheat in a celebration of the new harvest —we were then uninformed of the important role they play in the village economy. Not until the ban did we begin to learn of the extensive exploitation of the opium poppy for nonnarcotic purposes based on the stalks as well as the seeds. Deprived of a major crop during a period of escalating inflation, the farmers at that time had spoken repeatedly of the difficulties they experienced in obtaining adequate substitutes for some of these poppy products, products that again became available with the renewed cultivation.

The seeds (also referred to as *haşhaş*) appear frequently in the local cuisine, especially in those dishes eaten during the long autumn and winter months. For example, dry-roasted and then ground in a mortar, they serve as a topping for boiled whole wheat kernels or embellish certain leavened village breads and biscuits cooked over an open fire. *Börek*, unsweetened filled pastries of almost infinite variety encountered throughout Turkey, acquire a distinctive character in poppy-growing districts such as Gölkaşı. The ground seeds are either kneaded into the dough or, in combination with such ingredients as white cheese, cured meats, and herbs, constitute part of the stuffing. The dessert *baklava*, well known in its more standard versions, benefits similarly from this resource where available. As a highly prized flavoring agent, the seeds of the opium poppy have become associated with treasured regional specialties. In the tradition of village hospitality, these delicacies—such as the sweet prepared from poppy seeds and *pekmez* (grape molasses)—are often prepared for the honored guest.

If poppy seeds in cooking represent a source of domestic pride, the oil extracted from them is a commodity of real monetary significance. After setting aside a relatively small amount of the yield for kitchen use and the next planting, the Gölkaşı farmers bring the remaining seeds to a small mill in the nearby town of Beyşehir, where the heavy, sweet, nutty oil is extracted. According to the present governmental policy, each licensed family may be authorized to cultivate up to 2.5 decares (0.6 acres). With a maximum average crop of about 550 pounds of seeds per field, the poppy oil obtained is some 220 pounds. This quantity is usually sufficient to meet or at least markedly supplement a family's yearly need for cooking oil, a very expensive and sometimes unavailable market product. After all their oil has been extracted, the pressed seeds are not discarded but formed into cakes of protein-rich cattle feed.

High in polyunsaturated fatty acids and slow to turn rancid, unrefined poppy seed oil is used by the villagers primarily in meat and vegetable dishes. Its pronounced but pleasant taste is not considered suitable for the many regional salads, which, we have been told, include a spring salad of fresh poppy leaves picked before the flowering of the plant. Poppy seed oil was once exploited for far more diverse purposes. In rural areas, it served as a nontoxic oil for lighting, and industrially, it provided a base for varnish, paint, perfumes, soap, and medicinal emulsions. Given the limitation of opium poppy cultivation in Turkey during the past forty years and the recent decline in world demand, which resulted in a 50 percent reduction in land under cultivation in 1978–79, such subsidiary uses have vastly decreased.

With the poppy straw method, the capsules—emptied of their seeds—are delivered by the farmers to provisional government purchasing centers. The

*The edible, oil-rich seeds, below, are removed through a longitudinal cut; and the empty capsules, right, are sold to government agents, who ship the harvest to pharmaceutical factories.*

yearly price, calculated generously in order to encourage strict observance of the law, is nevertheless commensurate with other crops so as not to attract new cultivators. To date, the capsules have necessarily been shipped outside of Turkey for the final processing into morphine and codeine. However, an alkaloid factory in Bolvadin, some 80 miles to the northwest of Beyşehir, has been designed to meet all domestic as well as export requirements and should be operating by the end of 1980.

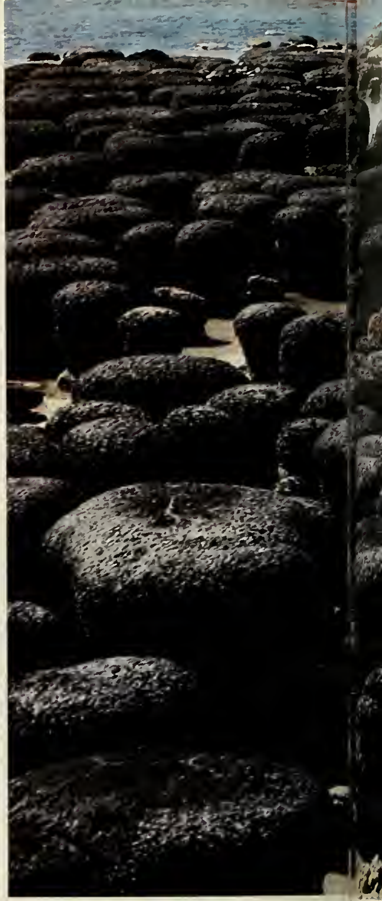
The use of the opium poppy plant is not restricted to the products of the capsule and its seeds. The dry stalks, headless after the capsule collection, are uprooted and transported back to the village where they serve as animal litter and, more important, fuel. The opium-growing regions of Turkey, concentrated on the Anatolian plateau, are generally very poor in timber. A pollen core extracted at the southern end of Lake Beyşehir by paleobotanist Willem van Zeist of the University of Groningen, the Netherlands, reveals that the deforestation of this area was already under way by at least 4500 B.C. An effect of land clearance by early agriculturists, the present-day treeless landscape is the end result of continuous and relatively dense habitation of the Beyşehir basin over some eight millenniums. The Gölkaşı farmers have begun to reverse the denuded conditions by planting poplar and fruit trees in their gardens, but these are rarely employed as firewood. For fuel, the villagers must depend on dung cakes, costly coal and bottled gas, or the poppy stalks. The clean-burning stalks, a highly valued final bounty of the opium poppy harvest, help meet another essential domestic need.

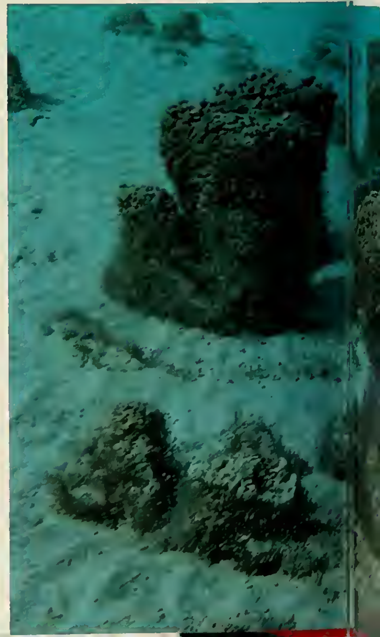
Our long-range, if initially unintentional, investigations into opium poppy cultivation end at present on an auspicious note. The United Nations Commission on Narcotic Drugs has, in its yearly reviews since the 1975 harvest, cited the current success of the Turkish program in preventing illicit opium production while contributing to the world's medicinal needs. Furthermore, implementation of the poppy straw process, by reducing the labor input and amplifying the seed yield, represents a rare perpetuation and even enhancement of ancient lifeways by modern technology. ☐

# Australia's Stromatolite Stronghold

*An uncommon blue-green algal structure, once widely distributed, thrives in water unfavorable to most marine herbivores*

**Text and photographs by Phillip E. Playford**





Twenty-five years ago, a party of oil company geologists discovered that a shallow embayment on the western coast of Australia was home to algal stromatolites, living examples of the oldest megascopic life forms known from the fossil record. Organosedimentary structures built by blue-green algae, or cyanobacteria, stromatolites were widely distributed during the Precambrian period, more than 600 million years ago, and are indeed the most common fossils found in strata of that period. Recorded in rocks up to 3.5 billion years old, in the Pilbara region of Western Australia, stromatolites reached the acme of their development during the late Precambrian. They began to decline markedly early in the succeeding Paleozoic era, at the time of the first great expansion of marine animal life, and this decline has continued to the present, so that algal stromatolites are now uncommon in the world's oceans.

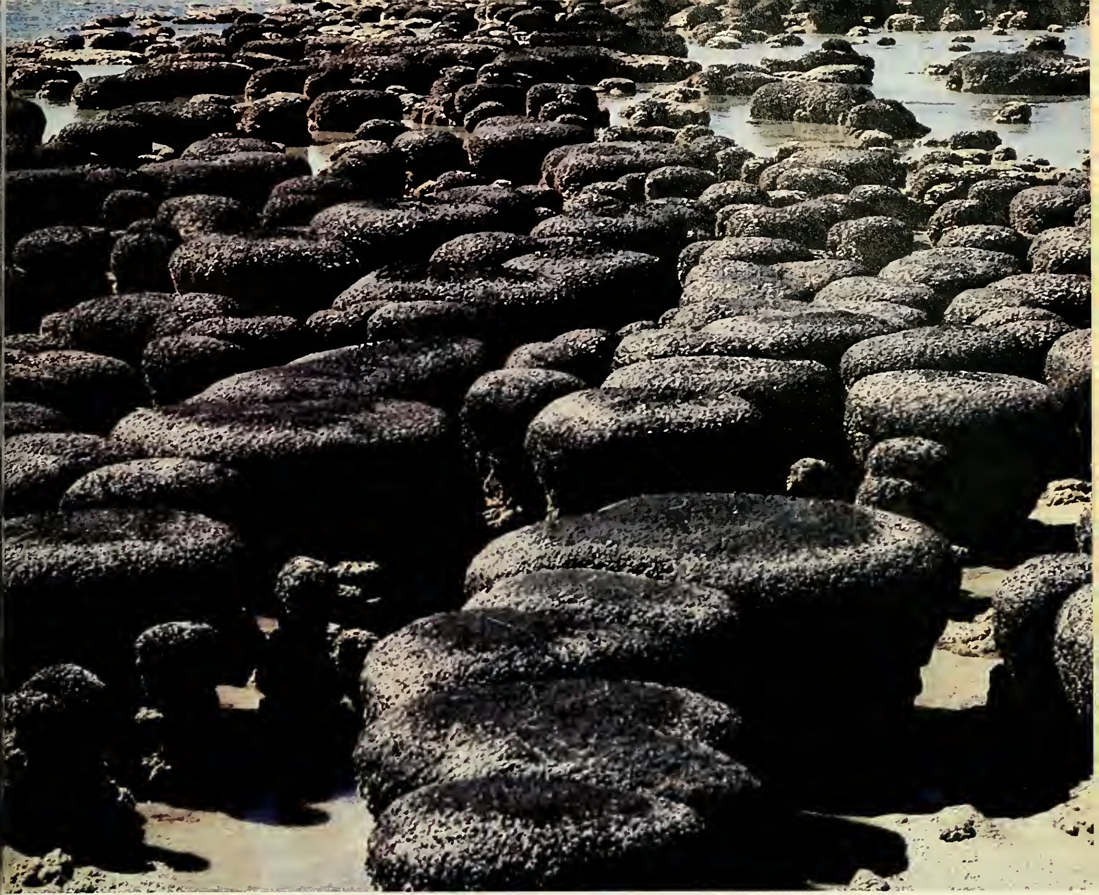
Their principal remaining stronghold is Hamelin Pool, which forms the southeastern arm of Shark Bay, 500 miles north of Perth in Western Australia. The algal stromatolites growing there are the most diverse and abundant known from modern seas. Geologists and biologists have studied Hamelin Pool and its stromatolites to determine the conditions that make this area favorable to the formation of these structures and, as a corollary, to understand why stromatolite-building blue-green algae have declined worldwide.

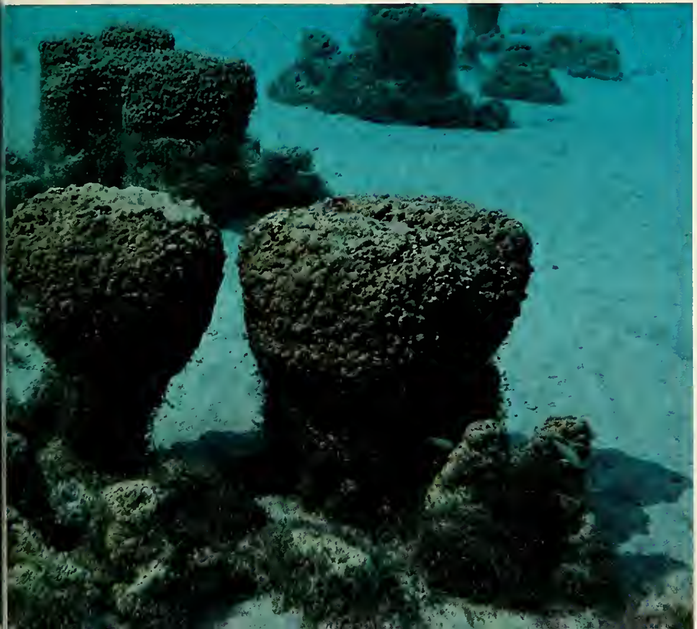
Hamelin Pool is a hypersaline basin, landlocked to the south, west, and east, and partly barred to the north by a shallow sand and sea grass bank known as the Faure Sill. The sill is cut by a number of prominent tidal-exchange channels up to fifteen feet deep, but water depth over most of the sill is less than three feet. Hamelin Pool itself consists of a central basin area up to thirty feet deep, surrounded by a shallow-water shelf and wide intertidal-supratidal flats. High evaporation (annual average about eighty-five inches) and low precipitation (annual average about eight inches) in this area combine with the restricted inflow of oceanic water across the shallow sill to produce salinities up to twice that of normal seawater.

Living stromatolites and the associated sheets of flat algal mats from which they develop cover extensive areas of the intertidal zone and shallow-water shelf, reaching depths of at least ten feet. Older, dead stromatolites, in varying stages of disintegration, commonly occur on the shoreward side of the living intertidal forms and extend to about three feet above sea level. Emergence of these older stromatolites was probably the result of periodic uplift during the past two to three thousand years.

The stromatolites are constructed of sedimentary material, such as shells and lime sand, that has been trapped and bound by matted filaments of blue-green algae. The sediment in, and immediately under, the living algal mats is soft, but a few centimeters below the surface it hardens progressively as a result of the precipitation of calcium-carbonate cement, so that most of the stromatolites are rigid structures.

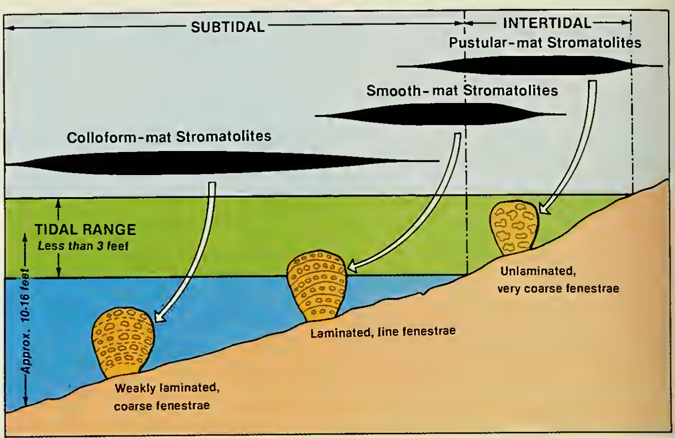
A wide range of shapes and sizes is represented among these stromatolites, from large club-shaped and cylindrical forms to small branching columns. Undulating and columnar shapes are the most common. Three main



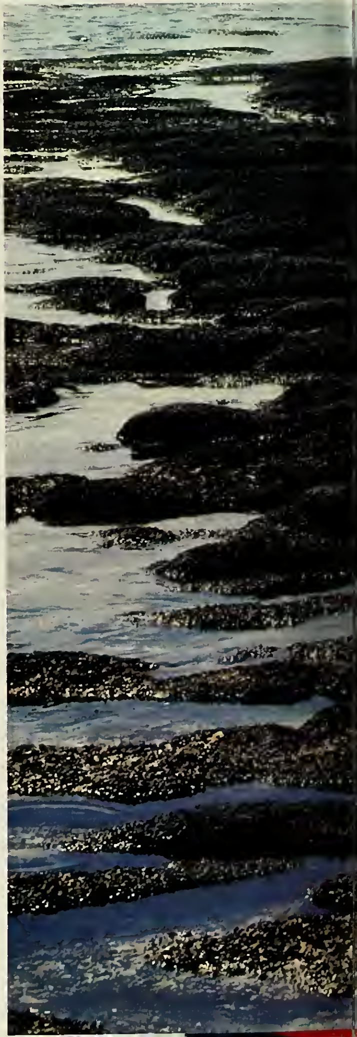


*Above: These living club-shaped stromatolites, photographed at low tide, were constructed by pustular algae, a common type in the intertidal region. Another type of algal mat—colloform—built the club-shaped, conical, and cylindrical stromatolites, left, which are growing in three-foot-deep water at the southern end of Hamelin Pool.*

Stromatolite Distribution at Hamelin Pool



*The strongly developed elongation of these living intertidal stromatolites, at right, is perpendicular to the shore (parallel to the direction of wave translation).*



types of algal mat, each composed of a different assemblage of algal species, construct the stromatolites, and the mat types show a zonation that passes from the upper intertidal region where the algal mat is mainly pustular, through the lower intertidal where it is mainly smooth, to the subtidal where it is mainly colloform.

The stromatolite-building algae occur only on the outer layer of a stromatolite; below the surface they decompose and are therefore not preserved. Nevertheless, some internal characteristics of a stromatolite, such as the presence or lack of lamination and the size and shape of any fenestrae, or internal holes, are governed by the type of algal mat that built it. Its gross, external shape, however, is mainly controlled by environmental factors, including the prevailing wave and wind directions and the nature of the substrate on which it has grown.

Many living stromatolites are elongate and perpendicular to the shore, parallel to the direction of wave translation, and some ancient elongate stromatolites may also have been wave controlled. Other Hamelin Pool stromatolites are elongate parallel to the prevailing southerly winds, which are especially strong and persistent in this area.

Because they generally require a hard foundation on which to grow, the stromatolites are commonly best developed around rocky headlands. Some prominent stromatolite reefs in Hamelin Pool grew on Pleistocene submerged beach ridges, and prominent lines of stromatolites within these reefs are controlled by strongly indurated beds in the underlying beach deposits.

Observations utilizing markers and photographs taken over the past twenty-five years show that the Hamelin Pool stromatolites are extremely slow growing. Most seem to be essentially static, with algal-mat growth approximately balanced by erosion, mainly during storms. The maximum net growth rate of stromatolites that have been marked for the past eight years amounted to less than half a millimeter per year. The slowness of growth suggests that many individual stromatolites must be hundreds of years old.

At one locality, a 1,000-foot-long wagon track cuts through stromatolites on the west side of Hamelin Pool. From about 1915 to 1935 camel-drawn wagons were used to load wool and sandalwood directly onto lighters anchored just beyond the belt of stromatolites. More than forty years have passed since the wagons were last used, but there has been little regrowth of stromatolites over the track, and even single sets of wheel marks that deviate from the main track are still clearly visible. This illustrates the extremely slow growth rates of the stromatolites and their vulnerability to damage by humans.

Fortunately, there has been relatively little human disturbance of the Hamelin Pool environment. The permanent population in the vicinity amounts to fewer than twenty persons on neighboring sheep ranches. The closest town is Denham (population 350), a small fishing and tourist center fifty miles away. The belt of intertidal stromatolites has been declared a nature reserve, and a proposal for extending this reserve over the whole of Hamelin Pool and 130 feet inland is now under consideration.

What is the reason for this unique occurrence of abundant and varied algal stromatolites in Hamelin Pool? The explanation is tied to the unusual hypersaline conditions prevailing there, which have resulted in a major reduction in the diversity of marine life and a paucity of animals that graze on blue-green algae. Of particular relevance is the virtual absence in Hamelin Pool of marine gastropods (snails), which graze on algae; elsewhere in Shark Bay, these animals are abundant. Several fish species occur in Hamelin Pool, some in relatively large numbers, and a single species of bivalve is very abundant, but the total fauna includes only a small fraction of that found in waters of more normal salinity on the other side of the Faure Sill. Although some of the fish in Hamelin Pool graze on blue-green algal mats, the rate at which these few species consume algae is insufficient to prevent stromatolite growth.

An understanding of why algal stromatolites are present in Hamelin Pool helps piece together an explanation for their decline worldwide. Blue-green algae are a remarkable group of organisms that are able to survive a wide range of ecological conditions; many can tolerate periodic desiccation and extreme ranges of temperature and salinity. Their wide ecological tolerance has enabled these organisms to persist, apparently without major evolutionary change, through at least 3.5 billion years of the earth's history. Stromatolite-building blue-green algae, however, have steadily declined in abundance since the early Paleozoic. No doubt a number of factors are responsible for this decline, but the main one is believed to be the proliferation of marine animals that graze on algae. As marine herbivores evolved and extended their habitats, stromatolites were progressively eliminated from most of their former ecological range. They were able to flourish only in environments that remained unfavorable to marine animal life. The best example of such an environment today is Hamelin Pool, where the restricted nature of the marine fauna is analogous to the low diversity of animal life in the world's oceans during the late Precambrian and early Paleozoic eras.

The history of the stromatolites' decline is thus an important ecological example of the progressive suppression of a biological group, forced to the extreme limits of its ecological range by the evolution and adaptive expansion of animals that utilize it as a food source. ☐

James H. Shaw

# Giant Anteaters

*Getting too close to this toothless creature could result in a fatal embrace*

**by James H. Shaw and Tracy S. Carter**

*By feeding for only about thirty seconds at a time and seldom varying their foraging routes, giant anteaters exert minimal predation pressure on a given ant or termite nest. This pattern assures the anteaters a steady supply of food.*

Somewhere in Brazil's interior, a nineteenth-century naturalist named Gardner chased a large, lumbering creature that looked like no other he had ever seen. Easily overtaking his quarry, Gardner seized the animal by its prominent snout and, to his surprise, found himself fighting for his life. The creature, which he thought harmless, rose on its hind legs and with stout forelimbs clasped the naturalist around the middle. Just as its sharp claws began their work on human flesh, Gardner's native companion struck the animal over the head with a club.

Gardner had heard that this strange beast subsisted entirely upon ants and termites, and its diet, together with its shaggy appearance, plantigrade hind feet, and curved claws, led to the animal's popular name "ant bear." Today it is better known as the giant anteater, *Myrmecophaga tridactyla.*

Unrelated to true bears, giant anteaters are members of the order traditionally known as Edentata, a group that includes sloths, anteaters, and armadillos, all of which are restricted to the New World. Although edentata means "without teeth," only the anteaters are completely toothless, while all other edentates have simplified teeth and lack teeth at the front of the mouth. Gardner felt perfectly safe in grabbing the anteater by the snout because he knew it couldn't bite him.

One characteristic shared by all anteaters, armadillos, and sloths is an extra set of articulations of the lumbar vertebrae. Known as xenarthra, these articulations provide additional support for the lower vertebral column, permitting many of these species to assume sturdy bipedal stances. Many zoologists believe that this order of mammals merits the more accurate and consistent name of Xenarthra.

Some of the earliest-known fossil xenarthrans were North American, but it was in the Tertiary (sixty-five million to two million years ago) environments of South America that the group achieved its main evolutionary success. One branch gave rise to the armadillos, of which there are about twenty living species, including the familiar nine-banded armadillo, the only xenarthran occurring in the United States. A second branch developed into five contemporary sloth species and four species of modern anteaters.

Geographically isolated throughout the Tertiary, South America reunited with North America about two million years ago, and a faunal exchange began. Some of the invaders from North America proved to be such formidable competitors that many South American species were driven to extinction. But the xenarthrans persisted, and some, such as the giant ground sloth, became well established in North America.

Xenarthrans are still a major mammalian group among South America's native fauna. In some places they are ecologically dominant, achieving greater biomass (the weight of living material) per unit area than any other group of mammals. Researchers at Barro Colorado Island, a tropical forest habitat in Panama, found that the biomass of sloths and anteaters exceeded that of any other native mammals. Thousands of miles to the southeast in the high-altitude Brazilian grassland of Serra da Canastra, a new 200,000-acre national park in Brazil's eastern highlands, we learned that anteaters and armadillos were the dominant animals. At the invitation of Brazil's federal conservation agency, we did field studies on the giant anteaters in the park and were fortunate enough to see eighteen giant anteaters there in a single day. Canastra's terrain made it possible to spot anteaters at distances of more than a mile. We made a series of counts and estimated the anteater population at between three and five per square mile, not bad for a large predator.

Giant anteaters average about six feet in length, stand two feet high, and weigh an average of seventy pounds. Their skull is longer than a grizzly bear's, yet scarcely wider than a jackrabbit's. Characteristic markings include long, coarse hair along the back and tail, distinctive, horizontal black bands on the forefeet, and a dark lateral stripe. This stripe tapers like a banner, leading to the popular Brazilian name *tamanduá bandeira*, or literally, "flagged anteater." Markings differ considerably between giant anteaters, often making it possible to distinguish between individuals. We named one anteater in our study area Wing because its lateral stripe resembled the outstretched wing of a bird.

Giant anteaters are tiny at birth. We weighed two newborns that tipped the scales at less than three pounds. By the end of their first year, anteaters weigh between twenty-eight and thirty-three pounds, apparently reaching full weight (seventy pounds) by the end of their second year.

Although the species still ranges from Central America to southern Brazil, it is officially recognized as endangered. The principal reason for its decline is deliberate killing by people, who regard the giant anteater as, at best, worthless or, at worst, dangerous. The meat is sometimes consumed, but the giant anteater has little commercial value. A low reproductive rate, no more than one young per year, makes it difficult for anteater populations to tolerate this relatively new form of mortality. The high population density in Canastra appears to be a rare exception brought on by the area's remoteness and, more recently, by protection within the national park. Some authorities believe that a similar pattern of killing brought about the extinction of the anteater's largest relative, the giant ground sloth. Evidence from both North and South America shows that prehistoric humans killed giant sloths, and some paleontologists have concluded that this overkill brought about the species' extinction.

Its low reproductive rate, poorly developed senses, and generally unwary nature make the giant anteater vulnerable. Because of its poor vision and none-too-keen hearing, the animal is forced to rely mainly upon its sense of smell. With the wind in our favor, we have frequently made observations from within ten feet of foraging anteaters in open grassland. This lack of wariness makes the anteater an easy mark for any sort of firearm or even a hefty rock. Riflemen often kill them, apparently for target practice. While conducting a field study in Canastra, mammalogist Bryan Glass discovered a giant anteater skull with a bullet hole punched neatly through the brain case. The animals make tempting targets, even in relatively protected areas.

Throughout South America the giant anteater is believed dangerous to

*Riding on its mother's back, a baby giant anteater aligns its lateral stripe with hers, so that the two animals appear to be one. The mother carries the cub in this fashion for several months, affording it a measure of protection from predators.*

Tom Stack; Tom Stack and Associates

humans. Brazilians even have a term for Gardner's traumatic experience, the *abraço da tamanduá*, or "embrace of the anteater," a sometimes fatal experience for those who get too close. One bizarre claim is that a giant anteater can suffocate a person by placing its snout over the victim's mouth and nose. Since the snout's diameter is only an inch or so at the tip, such a feat would require considerable cooperation by the victim.

Years ago, a wounded giant anteater was said to have killed a small boy in Ecuador. The youngster was accompanying some men on a hunt. When his father wounded a giant anteater, the boy tried to dispatch it with his machete. The anteater embraced and fatally clawed him.

How dangerous is the giant anteater? Surely Gardner's story and the Ecuadorean incident demonstrate that the animal is capable of injuring and even killing people. But to gain perspective on this question, we need to consider the species' life history, particularly how it deals with danger in its natural environment. For the past two million years, the giant anteater has shared its domain with big cats, notably the jaguar and the puma. Marsupial predators, including a saber-toothed version the size of a modern leopard, posed a danger to anteaters prior to the big cats' arrival. Since the anteater is unwary, slow running, and can barely climb trees, how has it coped with predators? The answer seems to lie in a rapid and effective defensive reaction in which the animal uses its sharp claws and strong forelegs. Dogs foolish enough to attack giant anteaters are usually disemboweled. South American Indians commonly state that giant anteaters even kill jaguars. While this last claim is difficult to document, the defensive reactions of giant anteaters have probably taught big predators to rely on

*An anteater plucks termites from a mound with its twenty-inch-long tongue. Contrary to popular belief, the anteaters' tongues are not sticky and they do not capture their insect prey by using that appendage as flypaper. The bites of ants can drive an anteater away.*

safer prey. The large claws on the giant anteater's forefeet may serve more for defense than for tearing into termite and ant nests, their presumed primary function. We have yet to see a giant anteater breaking into an insect nest and believe that most of their feeding is relatively passive.

The giant anteater responds to sudden attack from a human in essentially the same way it meets an attack from any other predator. Its actions are purely defensive and, as far as we know, can only be elicited by direct contact. In all our hours of closeup observations, we never felt the slightest bit threatened. Whenever an anteater detected us, it would invariably move away as fast as its clumsy gait could carry it, but the animal is poorly designed for hasty retreat. Its slow running motion has been compared to that of a rocking horse. When running or walking, the animal protects its claws by tucking them under, turning them inward, and striding on the outer edges of its forefeet. This awkward arrangement results in a clumsy running gait, accentuated by the long, coarse hair flopping along its back. After running a few dozen yards, frightened anteaters often stop and begin feeding on the nearest ant nest, apparently forgetting that possible danger still lurks nearby.

The giant anteater's defense against predators poses a problem. A species endowed with formidable weapons needs a way to resolve conflict among individual members without inflicting serious injury. One way is ritualization, in which intent is expressed while physical combat is restrained. We once witnessed such a ritual when one giant anteater wandered into an area in which a second anteater was foraging. After catching the scent of the wanderer, the forager immediately ran toward it and the ritual began. The two circled one another with tails raised high and pushed at each other's shoulders with their forepaws. Serious injury was avoided since the deadly claws were kept carefully tucked. After a few minutes of circling and pushing, the combatants seemed to settle their dispute and each moved slowly away in the direction from which it had come.

*The size and shape of lateral stripes vary greatly among giant anteaters, making it possible for researchers to recognize the individual animals they are studying in the field. The heavy coat of hair probably helps the anteater save body heat.*

m McHugh, Photo Researchers

Another question that has long puzzled naturalists is, How can an animal the size of a giant anteater sustain itself on a diet of ants and termites? Only recently have key pieces of the puzzle begun to fit together. Part of the answer lies in the foraging pattern. Giant anteaters feed only half a minute or less on each ant nest, after which the biting and stinging of the insects apparently drive them away. Furthermore, anteaters tend to move in a constant direction between insect nests, seldom altering their foraging routes by more than a few degrees. This way they reduce the chances of raiding the same nest within their feeding ranges twice. The limited feeding time and movement pattern represent an efficient means of cropping prey and assure the anteaters a steady food supply.

There are a couple of persistent myths about the way in which anteaters feed. The first is that the beast captures insects with its "sticky" tongue. Although moist and equipped with tiny villi, the twenty-inch-long tongue is not sticky. Another related myth is that the giant anteater uses its tongue flypaper fashion to entrap entire columns of ants. After spending dozens of hours watching anteaters feed on thousands of insect nests, we have yet to see one lying comfortably beside a trail, tongue extended, collecting marching ants. A good idea, perhaps, but the anteaters haven't learned the trick.

Another part of the energetic puzzle was recently solved by Brian McNab of the University of Florida. McNab measured metabolism in the giant anteater and discovered that its basal metabolism was only about one-third that expected for a mammal of its size. Low metabolic rate means low energy demand and may represent a further adaptation to an unusually specialized diet. This low metabolism may also explain why the giant anteater, a tropical species, has developed such a heavy, dense, coat of hair. A mammal with so low a rate of metabolism may actually need that hair to retain body heat, even in the tropics. When sleeping, the anteater folds its bushy tail over its body to conserve body heat. This sleeping position also serves to camouflage the sleeping animal by breaking up any telltale outline.

Camouflage is also used by anteater cubs. A female anteater carries her single cub on her back for several months. The cub is hard to see because it clings where its mother's hair is densest. It seems to align its own exposed lateral stripe with its mother's, making the two appear to be one animal.

Other than females with young, giant anteaters are generally solitary creatures. When two adults are seen together there is no way of knowing whether or not they are a mated pair. The sexes can only be distinguished by close inspection. This similarity between sexes gave rise to a local belief near Canastra that all giant anteaters are females and procreate by mating with lesser anteaters (*Tamandua tetradactyla*).

Recently we used radio telemetry to study movements of giant anteaters but only after we overcame problems posed by the species' peculiar anatomy. Neck collars, the usual means of attaching transmitters to wild mammals, were inappropriate in this case. So we fashioned various kinds of shoulder harnesses with which to secure transmitters and found that they generally worked well. When a couple of the more determined animals learned to wriggle out of their harnesses, we recaptured them and, taking advantage of their long, coarse hair, actually braided transmitters onto them. The radio tracking showed quite clearly that home ranges overlapped in both sexes, indicating that the species is not territorial. However, territoriality among mammals is not so simple a proposition as it was once thought to be. Perhaps under different combinations of population densities and food supplies, giant anteaters might behave differently and maintain exclusive home ranges.

The outlook for the giant anteater is still good. While obviously vulnerable, it is widely distributed in different habitat types on a continent blessed with abundant ants and termites. The Brazilian government has granted the species protection, and new national parks such as Canastra will assure preservation of natural habitat. Perhaps people will become more tolerant of the anteater as they learn that it poses no real danger if unmolested. ☐

# Posing the American Indian

*Early photographers often clothed reality in their own stereotypes*

**by Margaret B. Blackman**

Several summers ago I returned to the Haida Indian reserve in northern British Columbia, where I had conducted anthropological research, and I recall being both startled and amused when a native bearing a Nikon camera turned to snap my photograph. (Coincidentally, I was giving a lecture on historic photographs of Haida villages taken during the last one hundred years.) Like many native subjects who have faced the cameras of anthropologists, I never saw the final product. Perhaps, fittingly, it is now part of a photo collection depicting anthropologists who have studied this Indian community. Today, cameras, photographs, and photo albums are as much a part of Native American culture as they are of the larger American community.

In the past, however, it was the white man who communicated the popular image of the Indian through paintings, drawings, and most important—in terms of their historical value—still photographs. In every picture we find two kinds of enlightening statements, one about the artist or author and his conception of the subject material and a second about the culture captured in the picture. These statements might be labeled "stereotype" and "reality," respectively. In recent years, the public has become more sensitive to the existence of stereotypes; the documentary value of the visual record, however, is just beginning to be realized.

*The earliest documented photograph of an American Indian is this 1847 daguerrotype, by Thomas M. Easterly, of Keokuk, leader of the combined Sauk and Fox tribes.*

ithsonian Institution National Anthropological Archives

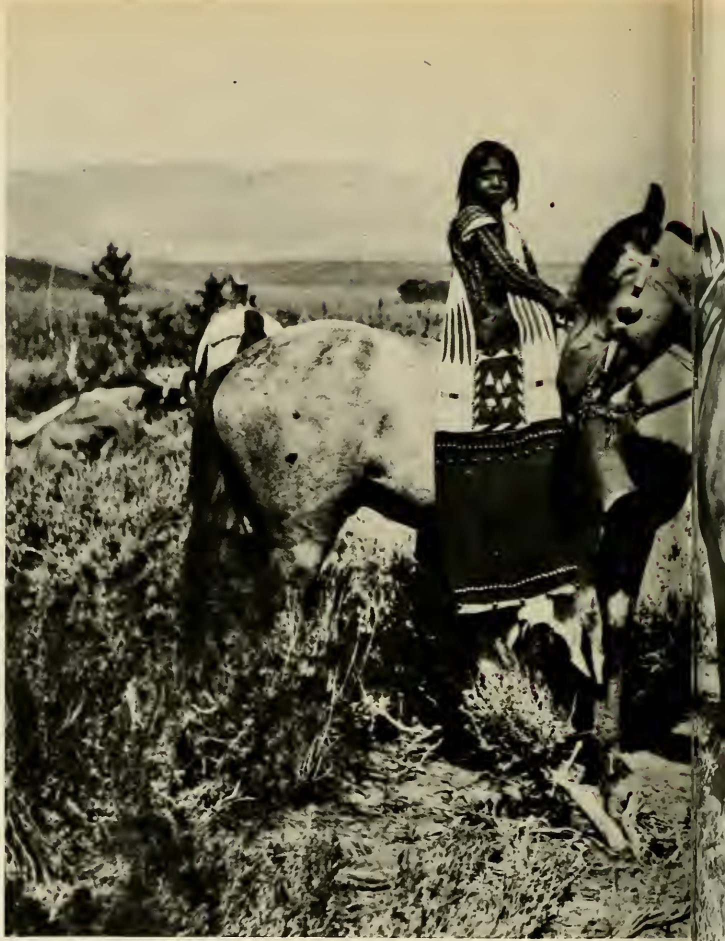
There is a wealth of photographs of American Indian life and culture. The American Museum of Natural History houses a comprehensive collection, and regional museums such as the British Columbia Provincial Museum have substantial holdings respecting local native cultures. Probably the largest collection belongs to the Smithsonian Institution, whose National Anthropological Archives has cataloged more than 30,000 black-and-white prints of American Indians.

Photography began with the invention of the daguerrotype in 1839, but slow exposure times (eight to thirty minutes) made recording anything that lived and breathed more than a little difficult. Nevertheless, with headrests and patience on the part of the subject, portraiture with the daguerrotype was possible. The earliest documented photograph of an American Indian is an 1847 daguerrotype of Keokuk, leader of the combined Sauk and Fox tribes after the War of 1812. Several years earlier both George Catlin and Charles Bird King had recorded Keokuk's likeness on canvas. King, a portrait painter, became famous for his renderings of Indian visitors to the nation's capital. By the late 1850s, however, the camera had supplanted portraiture, and Indian delegations had their images recorded in photography studios.

Occasionally, a photographer accompanied a treaty party from Washington, D.C., to the West, but documentary field photography did not become established until after Mathew Brady used his camera to register the travails of the Civil War. By the 1870s photographs of Native Americans in their home settings were no longer the exception, although photography was still a cumbersome process. William Henry Jackson, official photographer on the 1870 Hayden Expedition, carried with him a staggering array of equipment and supplies, including three cameras, two tripods, a dark tent, many pounds of chemicals, and four hundred glass negatives. Jackson and other photographers of his time relied upon the wet-plate process, a procedure that required coating the glass-plate negative with a light-sensitive emulsion, then exposing and developing the negative while the emulsion was still wet. It took Jackson half an hour to make and process a negative. Exposure times with the wet plates were still fairly slow—ten to fifteen seconds—and American Indian life recorded by the wet-plate process was a still life.

In 1871 the British *Journal of Photography* reported the invention of gelatin-coated glass-plate negatives that did not require exposure and developing while still wet. But these early "dry plates" were even less light sensitive and thus slower than contemporary wet-plate negatives. By 1880, however, when the dry plate was officially sanctioned by the Photographers' Association of America, exposure times had been reduced to one-

*"A warrior and his bride" were among the Ute Indians posed by John K. Hillers, photographer on Major Powell's 1873 Colorado River Expedition. Such pictures were often made for public consumption.*



Smithsonian Institution National Anthropological Archives

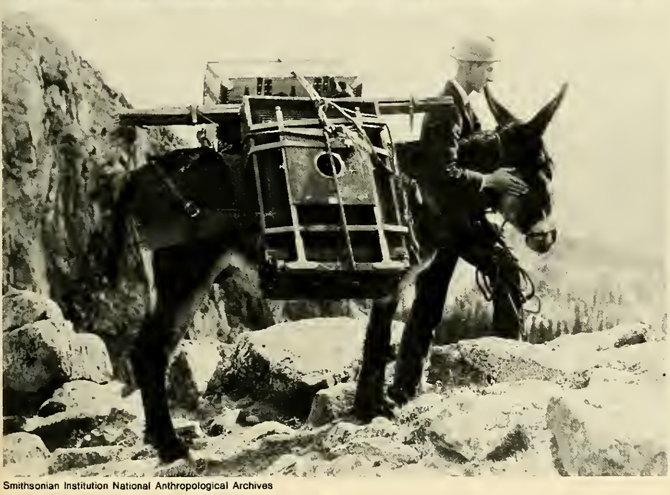
sixth to one-twelfth that of the wet plates. Two years later the dry plate was firmly entrenched in American photography. Nevertheless, some time probably went by before Indians in well-traveled areas of the country became familiar with the faster process. In 1885, for example, a Tlingit Indian boarded an Alaska Steamship Company steamer docked at Sitka and, seeing a photographer taking pictures on deck, requested to be photographed. An observer reported, "The Indian stiffened himself into his most rigid attitude and when the process was over could hardly be made to stir from his pose."

While photographers often accompanied early ethnographic expeditions to Indian settlements, their motives were usually not strictly ethnographic. John K. Hillers, who served as photographer for John Wesley Powell's 1873 Colorado River Expedition, provides a good example. A number of Hillers's photographs of Ute and Paiute Indians were used by Powell to illustrate some of his publications on Great Basin Indians. Many, however, were taken with a stereo camera and mounted on cards for viewing through parlor stereoscopes, evidence that entertainment value governed the selection of subject matter. The barebreasted "Wu-nav-ai gathering seeds" certainly was not viewed by Victorian gentlemen for its documentation of Great Basin seed gathering. Hillers's stereo images, marketed with a U.S. Department of the Interior label on the backs of the cards, proved most lucrative, netting $4,100 in the first six months of their sale in 1874.

Even Franz Boas, the father of American anthropology and meticulous chronicler of Northwest Coast Indian cultures, saw photography of Native Americans in commercial, as much as ethnographic terms. In the winter of 1895/96 Boas hired C.O. Hastings, a photographer from Victoria, to accompany him to Fort Rupert and assist in recording Kwakiutl Indian technology and portions of the elaborate winter ceremonies then in progress. Together, Boas and Hastings returned with 140 photographs, which the anthropologist hoped to be able to sell to *Scribners* or some other magazine. The *Scribners* photo essay never came to fruition, but many of the photographs illustrated Boas's *The Social Organization and Secret Societies of the Kwakiutl Indians,* published in 1897 as a U.S. National Museum Report, and these, and others, are in the photo archives of the Smithsonian Institution and the American Museum of Natural History.

With expedition photographers and even, I suspect, with Boas, there was a strong motivation to photograph what would sell to the public; and the more exotic, the more salable. As far as many early photographers were concerned, the costume made the Indian. Researcher Joanna Scherer (to whom goes credit for previously presenting and analyzing many of the photographs republished here) has described how the Plains Indian stereotype was imposed upon the non-Plains Ute and Southern Paiute when Hillers photographed many wearing buckskins and feather headdresses, costumes that had been ordered by Major Powell. Frontier studio photographers routinely kept a stock of Indian costumes with which to attire local native subjects. The result was that several natives were often photographed in the same outfit or one native might be photographed in two or more different outfits.

Edward Sheriff Curtis, the most famous photographer of Indian subject



Smithsonian Institution National Anthropological Archives

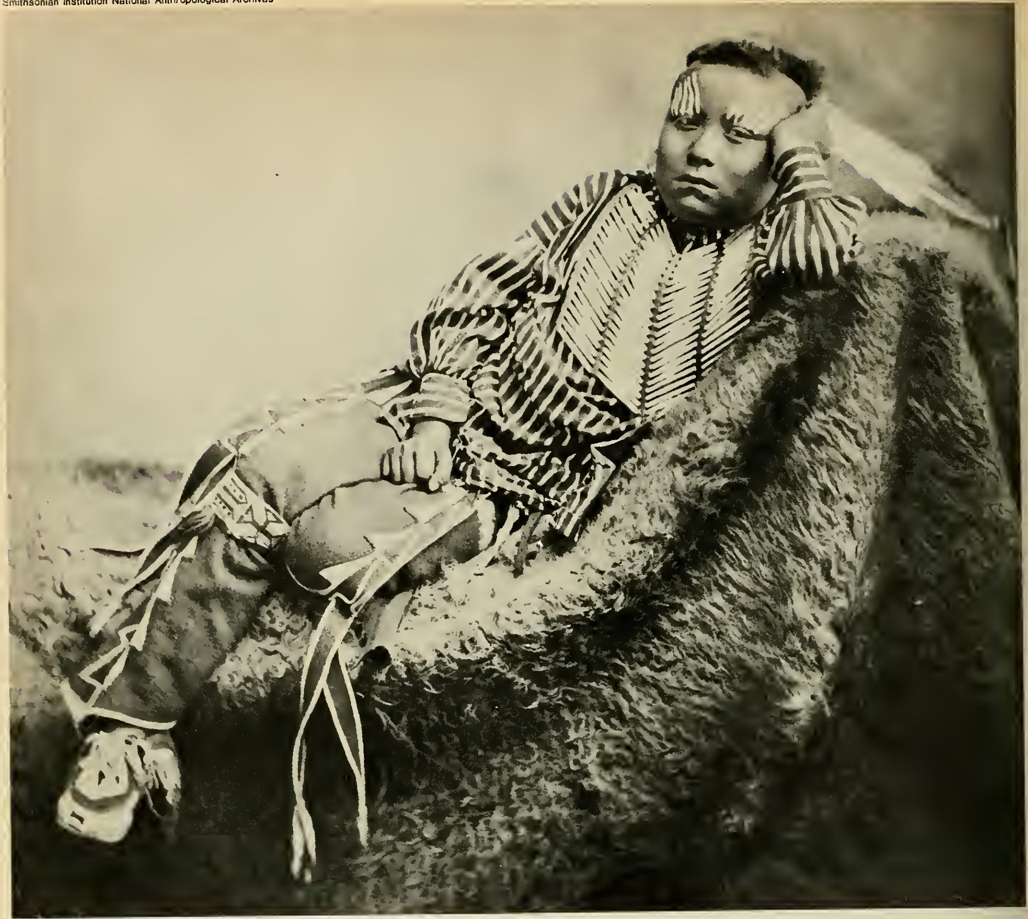
material, costumed his subjects with much greater attention to ethnographic accuracy. Over a period of nearly thirty years, Curtis visited more than eighty different Indian groups, collecting ethnographic material for his *The North American Indian,* published in twenty volumes between 1907 and 1930. His volumes were illustrated with some 700 photographs culled from the more than 40,000 he took in his travels. Curtis had a romanticized view of the American Indian, but one that was tempered with the ethnographer's concern for accuracy. Writing of his photographic work, Curtis said, "These pictures were to be transcriptions for future generations that they might behold the Indian as nearly lifelike as possible as he moved about before he ever saw a paleface or knew there was anything human or in nature other than what he himself had seen."

To effect a precontact image of some of his subjects, Curtis carried with him a wardrobe of museum props. In 1971 while doing research on historic photographs of Haida culture for my doctoral dissertation, I discovered that Curtis's props did not stop with garments and ceremonial paraphernalia. I was baffled that older Haida recognized all the Haida women Curtis had photographed but could identify none of the men in his photographs. Finally, an older man recognized the face of Alfred Adams in one portrait, but noted that, in contrast to the Curtis image of him, Adams had always worn his hair short in the style of the early twentieth century. Later I learned that all the Northwest Coast males in Curtis's photographs were bewigged. The short haircuts of the native men would never have served to present the view of the native that Curtis tried to reconstruct before his camera.

Curtis's hauntingly beautiful photographs do evoke a mood, and his much admired images sparked imitation of the genre. One such imitator was B.W. Leeson, a British Columbia

*Field photography once involved the transport of glass negatives and other heavy equipment. On the 1870 Hayden Expedition, William Henry Jackson photographed his "assistants."*

Smithsonian Institution National Anthropological Archives



*Lone Bear's face paint was apparently added after his picture was taken by William Soule. The boy wears an Osage costume, but since he also posed as a Kiowa, his tribal identity is uncertain.*

photographer, who wrote of his successes in photographing Indians for *Cameracraft* magazine in 1914. Leeson, like Curtis, knew artistic license was quite possible with the camera, that the photographer could depict the subject as he wished. In Leeson's case, however, the result was often a contrived sentimentality. Leeson was especially fond of "The Passing of the Indian," a photograph he made and marketed; he revealed the secret of its success to *Cameracraft* readers:

> I have always appreciated the difference between a record photograph and a photographic picture and have made many attempts at the latter; the picture, "The Passing of the Indian" being one of my latest and most successful efforts. The figure is that of the last remaining member of the Klaskeno tribe who lives with his wife here at Quatsino. I explained to him just what I wished to do, show him as the last of his tribe, asking him to look "sick tum tum" and he responded quite well.

The power of the pictorial was recognized by Indians themselves, who were not only subjects for photographs but often customers as well. Leeson catered to their tastes.

> It is the liking of the younger Indians, particularly the girls, to fix up and be photographed. Asked to pose [for traditional shots] they will rub on white paint, blacken their eyebrows and squeeze themselves into tight corsets, looking about as impossible, from a pictorial point of view as they can. I pose them inside some ranch enclosure with a strong front light, and then, with a little manipulation of the negatives, I make them look like beautiful blondes. They will each want one print.

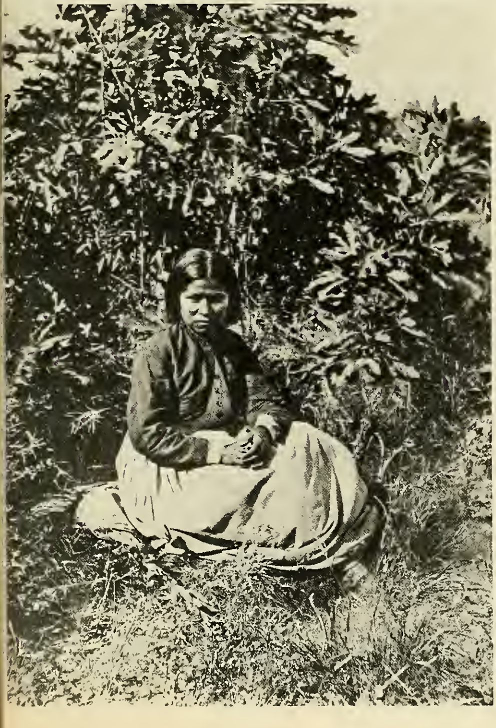
Not all Native Americans were lured into seeking the photographer's services in order to look like whites; by the turn of the century, many recognized the cultural and personal historical value of the visual record. What else could explain the hiring of a photographer to record a family funeral, a wedding, a family gathered on the front porch of its home, the village band, and other mundane, nonexotic scenes? Such photographs were not studio-marketed curiosities; they were commissioned by Indians for Indian use. One elderly Haida woman I know, the legatee of nearly one hundred early-twentieth-century images, realizing their larger historical value, lent them to the Smithsonian for copying. They speak to the realities of native life as it actually was when Curtis was busy trying to recapture it as it had been some two hundred years before.

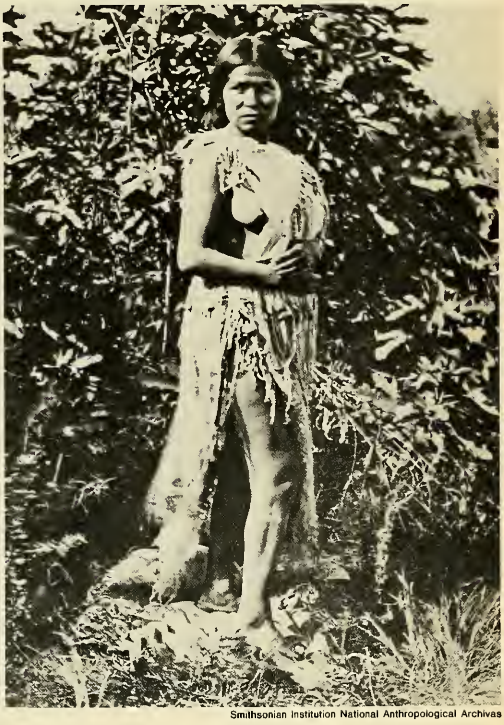
For the anthropologist and historian of American Indian cultures, photographs of Native Americans are important if for no other reason than photography evolved at a time when these cultures were undergoing rapid, intensive change. Unwittingly perhaps, photographers documented many changes that few anthropologists of the time were interested in, concerned as they were with reconstructing the past. Two examples from the Northwest Coast hint at the uses to which photographic documents can be put and the kinds of problems they shed light on.

The Haida village of Kasaan in southeastern Alaska was frequented during the 1880s and 1890s by U.S. revenue cutters, fisheries boats, and steamships of the Alaska Steamship Company on their cannery-tending junkets. Navy personnel, fisheries officers, and other government officials, as well as tourists aboard these ships had a hand in making Kasaan the most photographed Haida village. Although no one, except perhaps the earliest photographer of the village (Albert Niblack, in 1885), set out to systematically record the entire village, there are more than seventy photographs, taken between 1885 and 1902, when the village was abandoned, recording every house, every totem pole, and virtually every deletion and addition to the façade of the settlement. We know largely, if not exclusively, from the photographs how Kasaan's people were affected by the introduction of Christian mortuary customs, how they adapted white styles of architecture to their native dwellings, what innovations they made in the carving of totem poles, when they quit raising totem poles, and a number of other particular cultural changes. And for those interested in how abandoned villages in the Northwest Coast rain forest deteriorate, and the rapidity with which such deterioration takes place, there are numerous photographs of Kasaan taken at intervals after its abandonment.

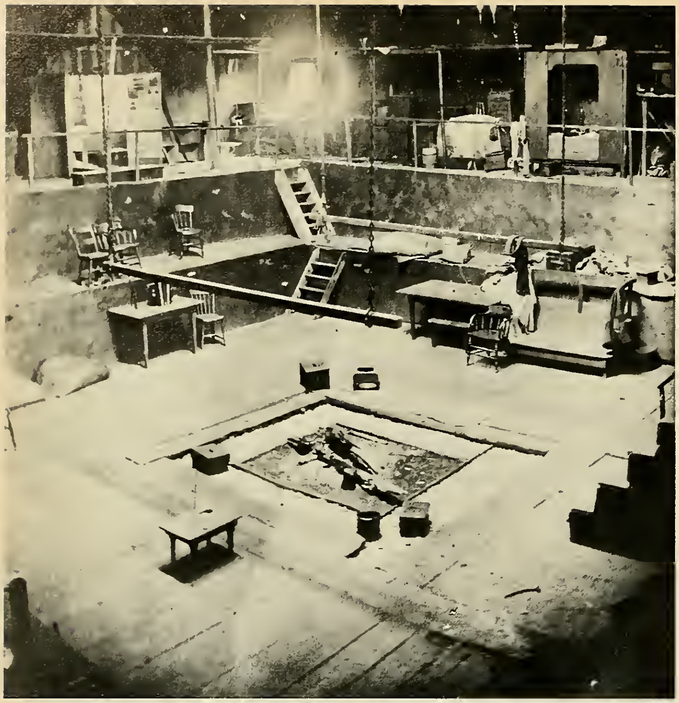
Some sixty miles to the south of Kasaan, in the village of Masset in the Queen Charlotte Islands, stood what was reputed to be the largest Haida house ever constructed, that of Chief Wiha. Perhaps because of the personage of its owner, its size, and its central location in the village, *Neiwans*—"the Monster House"—was one of the most photographed Haida dwellings. It was first featured prominently in George M. Dawson's 1878 photographs of Masset, and appeared in various photographs over the years. In 1897 E.P. Allen of the Field Museum in Chicago recorded an abandoned and weathered *Neiwans*, its side planks and windows missing. In 1919, Harlan Smith of the National Museums of Canada photographed *Neiwans*'s successor, a modest cottage less

*J.K. Hillers pictured Kaiar, a Paiute woman, modeling a garment, below, that if anything, is too elaborate for traditional summer wear. The calico dress, at left, is more likely her own.*





Smithsonian Institution National Anthropological Archives



AMNH

*Nonnative items arranged in a native space are evident in Richard Maynard's 1884 view of* Neiwans, *the house of a Haida Indian chief. Such photographs document an era of intense cultural change.*

than a third the dimensions of the former great house. An anthropologist who worked at Masset in the mid-1960s gave me a color slide of a two-story house that replaced the cottage in the 1930s, and more recently I photographed the modern one-story dwelling that stands on the site today.

The most revealing and intriguing view of Wiha's house comes from the American Museum's photograph collection. Taken originally as a stereo view by Richard Maynard in the spring of 1884, it depicts about two-thirds of the interior of *Neiwans* and is one of only a handful of photographs of Northwest Coast native house interiors from the last century. As a visual document, the Maynard photo says much about this Haida household's exposure to, and acceptance of, the wave of changes that had confronted it by the 1880s. The careful investigator can pick out a coffee pot, an accordion, a child's potty stool, newspaper photographs, and as many as thirty other items of nonnative origin shown in the photo, but he or she might have a hard time identifying anything distinctively native about the house's contents. The native artifacts consist primarily of cedar bark sleeping mats and storage boxes.

Yet all the material items are arranged within a native space; the organization of this household and the distribution of its nowhere-to-be-seen personnel was Haida, not Canadian. One can detect the importance of the upper level as reflected in the bedchambers; the attention given the rear portion of the house, with the chief's chamber and the several chairs and tables where Wiha or his successor may have entertained visiting dignitaries; the housepit as an area for social interaction, food preparation, and eating. We know, too, from other photographs of Masset that members of Wiha's house continued to occupy a native style of dwelling while others around them opted to build white-style houses.

The photographs of Wiha's house also prove instructive with respect to Haida architecture. It is possible to learn from the photographs and from archeological data at the house site some of the actual dimensions of the structure and several of its associated totem poles, features that disappeared about 1904 when the house and poles were razed. A lower housepit retaining wall, measuring forty-six inches in height, is preserved intact beneath the present house that sits on the site. Using this single dimension, it is possible through photogrammetry (a science for determining true distances from measurements made on photographs) to obtain measurements for all the house parts shown in the photographs. Applying the method on a larger scale, plans and elevation drawings of the entire village could be reconstructed to scale and might help an anthropologist inspect settlement patterns in great detail or might form the basis for actual reconstruction of portions of the village at some future date. Large-scale photogrammetric reconstruction of village sites has already been applied in at least one southwestern Pueblo Indian settlement.

The visual record of Native American cultures from the last one hundred years or so has much to offer to people of diverse interests. For the cultural anthropologist, such as myself, it reveals something of day-to-day life during a period of time that was not of much interest to an earlier generation of anthropologists, who looked to more remote periods of cultural history. For the archeologist, photographs of villages and housing complement and augment the artifacts excavated at village sites. And for the native descendants of those photographed, the images are a personal history of a bygone era. The visual record has much to communicate about stereotypes of American Indians, the way they really lived, and the contact and, sometimes, conflict between opposing ways of life. ☐

*To Sky Striking the Earth, who sat for William Dinwiddie at the Smithsonian in 1897, a feather duster may have seemed the best available substitute for a traditional Chippewa headdress.*

# A New Supernova

*An unfamiliar exploding star provides insights into these objects*

**by Stephen P. Maran**

Stellar explosions, or supernovae, are relatively rare in any one galaxy. Studies of spiral galaxies indicate that they occur typically at rates of one to ten per century in large galactic systems such as our own. The last authenticated supernova seen in the Milky Way was Kepler's star of A.D. 1604. (Another may have occurred later in the seventeenth century but was somehow missed by all or almost all observers.)

Supernovae discovered by amateur astronomers are especially rare. But last year, an amateur astronomer alerted professionals to a supernova in a faraway galaxy. Monitoring the event with satellite and ground-based telescopes, the professionals gleaned new facts about the progress of the explosion, the previous state of the disrupted star, and the distant galaxy itself.

The amateur was Gus E. Johnson of Swanton, Maryland, a member of the American Association of Variable Star Observers. That group, AAVSO for short, encourages its lay members to study pulsating stars and to search for exploding ones. It was to AAVSO headquarters in Cambridge, Massachusetts, that Johnson made his report. The report came in on April 19, 1979, the night after he had made a visual "tour" of northern galaxies, inspecting one after the other with an eight-inch telescope.

Midway through his April 18 tour, Johnson turned the small telescope toward M100, a striking spiral galaxy seen nearly face-on from the earth, in the constellation Coma Berenices. An unfamiliar star of the eleventh magnitude, fairly bright by telescopic standards, stood out against the galaxy. Either it was a foreground star, relatively near the earth, which Johnson had not noticed before, or it was in the distant galaxy and hence must be immensely bright. In the latter case, the object would have to be a supernova, for such exploding stars outshine all other stars until their erupting matter has thinned out as it continues rushing into space.

A check with the *Hubble Atlas of Galaxies* showed that the object was not a foreground star, and spectograms taken with professional telescopes soon confirmed that it was a supernova of Type II, meaning the explosion of a massive supergiant star. Subsequent calculation indicates that Johnson's star, the fourth supernova found in M100 since 1901, was about 6.3 billion times brighter than the sun, although visible only with a telescope.

The estimate of the brightness is at best approximate because astronomers' measurements of the distance of the M100 galaxy are in conflict, ranging from 37 million to 78 million light-years. (One light-year, the distance traveled by light moving at 186,000 miles per second during the course of a year, is about 5.8 trillion miles.) In any case, the brightness of the Johnson supernova surely exceeded three billion suns, with the larger above estimate the best guess at present.

Since supernovae have been lacking in the Milky Way recently, astronomers have perforce focused on other galaxies to study them. By scanning many galaxies, one can find several supernovae per year, even though the explosions are rare within any one galaxy. Two computerized telescopes have been developed to search the galaxies, but they have not been very successful and most supernovae are still discovered on patrol photographs made with simpler telescopes. The problem with patrol photography, however, is that unless the film is developed and carefully examined immediately (which doesn't always happen), a supernova will have faded substantially by the time it is noticed on the photographs and astronomers will miss the chance to observe the rapidly changing early stages of the explosion.

By contrast, a visual search such as Johnson's has the advantage of letting the viewer know at once that a supernova may have been found. The disadvantage is contained in the word "may": most visual supernova sightings turn out to be false alarms. Further, using only the eye and telescope, even careful searches are limited to relatively bright and nearby objects and hence miss the many fainter, more distant supernovae that are found by time-exposure telescopic photography. According to the AAVSO, Johnson may be only the second person to visually discover a supernova in the twentieth century.

Immediately after the discovery was announced, astronomers began studying the new star, which was brighter than usual for an extragalactic supernova. The most extensive efforts were made by a team of twenty-three European researchers led by Nino Panagia, a supernova expert at the Radio Astronomy Institute in Bologna, Italy.

Using ground-based telescopes, the team measured the velocity of the hot gas erupting from the supernova. It was found to be about 6,200 miles per second at first and slower later on. As the gas expanded, the supernova began to fade. Each night the star became about 4½ percent less bright. Radio telescopes in West Germany and New Mexico, also searching for the supernova, have found no signals from it yet but may detect it eventually when the expanding gas cloud is sufficiently thin and large. Two satellites looking for X-rays have also had no reported success so far.

The most interesting findings have come from a series of observations that Panagia made with an ultraviolet observatory satellite, the IUE (see "Telescope in Space," *Natural History*, July 1980). With the satellite equipment, he photographed the changing ultraviolet spectrum of the supernova and found three principal features, each corresponding to a different property of either the star or of its parent galaxy, M100.

The first feature was the continuum, that is, the general glow of ultraviolet light at all wavelengths. Analysis shows that this radiation comes from the outermost layer of the expanding gas that is still opaque. (Above the layer, light travels freely through the thinner gas; in the denser region below, light is strongly absorbed.) A layer of this sort, which resembles a surface when seen by an external observer, is called a photosphere, or sphere of light. That opaque layer is the same region that produces the visible light of the supernova seen from the ground.

Over a period of six weeks in April and May, the Europeans found that the photosphere cooled from about 11,000°C to about 7,000°C as it expanded. As the gas thinned, light escaped from deeper layers, where material ejected from the explosion at lower speeds was located. (The fastest stuff, of course, must be farthest out.) This circumstance probably accounts for the gradual slowing of the expansion, which as mentioned above, was found with ground-based telescopes. Gravity had a slight retarding effect, but the observed "slowing" may be mostly an illusion caused by the gradual uncovering of slower-moving gas that was present all along, while the faster-moving gas thinned and faded away first.

The second feature found by the IUE satellite was the absorption lines, that is, dark, narrow bands where the continuum light is reduced due to absorption by atoms along the line of sight to the supernova. In the July 1980 Sky Reporter column in *Natural History*, I told how such lines have revealed the presence of a "galactic corona" of thin, hot gas around the Milky Way. Thanks to its great brightness, the M100 supernova functioned effectively as a background lamp against which Panagia detected the absorptions of the Milky Way's corona and also a second set of similar absorption lines produced in M100 itself. (The two sets were readily distinguished as all the lines in the second set had red shifts corresponding to the 1,000 miles per second motion of the M100 galaxy away from the earth. This motion is caused by the expansion of the universe.)

The existence of the second set of absorption lines indicates that the M100 galaxy also has a corona. Co-

If you'd like to know more about our water, or the old-time way we make Jack Daniel's, drop us a line

OF THE 2,531 CAVES in Tennessee, this one in Moore County is particularly prized.

It's fed, you see, by an underground, iron-free spring flowing at 56° year round. Mr. Jack Daniel, a native of these parts, laid claim to the cave in 1866. And from that year forward, its water has been used to make Jack Daniel's Whiskey. Of course, there are hundreds of caves just as lovely. But after a sip of Jack Daniel's, you'll know why this one is valued so highly.

ronas may be a characteristic feature of many galaxies; one that is too dim in visible light to be seen on telescopic photos but that can be detected by ultraviolet spectroscopy.

The third and most interesting feature Panagia found was a set of broad emission lines. These are bright bands in the spectrum, at wavelengths where electrically excited atoms emit their characteristic radiations. Emission lines were also noted in the visible-light spectrum of the supernova, but the ultraviolet emissions differed fundamentally from them.

Interpretation in terms of the Doppler effect showed that the visible-light emission lines are produced by atoms in a gas erupting with speeds as high as 6,200 miles per second, while the ultraviolet lines came from material expanding at the much lower (although still impressive) speed of about 2,500 miles per second. Further, the visible-light lines showed a deficiency of red-shifted light, corresponding to gas expanding from the supernova in the direction away from the earth, while the ultraviolet lines had no such deficiency. This difference was the main clue enabling Panagia to explain the different origins of the matter producing the visible and ultraviolet emission lines, respectively.

Panagia's explanation is as follows: the visible-light lines come from a region that, although expanding, is still relatively small. Small enough, in particular, so that the matter in this region on the far side of the central exploding star (and hence expanding directly away from the earth) is hidden by the star itself. This region is probably located just above the photosphere already mentioned. Since the rear hemisphere of the region is hidden by the star, it does not contribute light to the emission lines observed from the earth. Thus, there is not much red-shifted light in the visible emission lines.

On the other hand, the source of the ultraviolet emission lines is ascribed to a layer that is much larger in size than the photosphere. Since this layer is so big, only a negligible part of its rear hemisphere is hidden by the central star. Thus, the larger layer yields essentially equal amounts of red- and blue-shifted emissions. (Motion away from the observer produces red shifts; motion toward the observer causes blue shifts.) However, since the ultraviolet emissions indicate a smaller expansion velocity than the visible emissions, the slower-expanding layer, remarkably, is bigger than the fast-expanding layer.

If there had been only one stellar explosion, the fastest-moving gas would have traveled the farthest and would be on the outside, a situation exactly contrary to the above conclusion. There is no independent evidence for two explosions, however, and indeed no supernova has ever been seen to explode twice. This seeming dilemma can be reconciled with known properties of stars, even if we accept that there was only one explosion and it produced the more rapidly moving inner zone. The outer zone, the one that emits the ultraviolet lines, must consist of gas that left the star long before the explosion. If, as is generally thought, the previous state of a Type II supernova is a red supergiant star, the source of this outer zone material can be identified.

Red supergiants are notable for their steady streams of cool gas, which flow outward in the form of so-called stellar winds. The outer zone of the M100 supernova, expanding now at 2,500 miles per second, probably consists of gas carried outward in such a wind before the star exploded. The current expansion is proceeding at roughly 100 times the estimated wind speed, however, an important discrepancy that must be confronted. The most likely suggestion is that a burst of X-rays from the initial moment of the supernova explosion was absorbed in the wind material. This great pulse of energy compressed, heated, and accelerated the gas, producing the rapidly expanding zone that now shines brightly as a source of ultraviolet emissions.

This theory by Panagia remains to be proved. In particular, calculation indicates that the wind before the explosion must have carried off mass at a much greater rate than is commonly observed in red supergiants. Nevertheless, it does seem likely that the supernova has illuminated and excited material that left the same star in an earlier phase of its life. Future analysis may yield insight into the nature of the events that transpired as a massive star burned brightly and inexorably toward an explosive fate.

# Celestial Events

by Thomas D. Nicholson

**The Moon** Evening moonlight doesn't show up until late in the second week this month, when the early crescent moon appears. The moon is new on October 8, first-quarter on the 16th, full on the 23rd, and last-quarter on the 30th. It will be new again on November 7 and first-quarter on the 15th. Apogee moon (farthest from the earth) is on October 9 and November 5; perigee (nearest the earth) on October 23. The full moon of October 23 is the hunter's moon. Since perigee occurs close to the date of the full moon, watch for exceptionally strong tides on October 23 and 24.

**Stars and Planets** During October, Jupiter joins Venus to become prominent in the morning sky. Venus isn't as bright and rises later compared to its performance last month. Jupiter, on the other hand, is steadily improving, rising earlier and appearing higher at dawn. The moon will guide you to Jupiter on the 7th, but after mid-month the planet stands high enough at daybreak to be seen easily. Jupiter rises later and appears lower than Venus all month, but the distance between them diminishes, and Venus catches and passes Jupiter at the end of October. By then, Saturn comes into view in the morning, lower than Venus and Jupiter and much dimmer.

During October, the sun moves through the stars of Virgo, passing into Libra on the 30th; Mercury moves out of Virgo into Libra early in the month, Venus moves from Leo into Virgo at the end of the month. Mars spends early October in Libra, about a week in Scorpius at mid-month, and the end of the month in Ophiucus. Jupiter and Saturn are in Virgo, Uranus is in Libra, Neptune in Ophiucus, and Pluto in Bootes.

October 4–5: Be sure to look for Venus, Regulus, and the waning crescent moon on both mornings, high in the east at dawn. Venus passes very close to Regulus at 11:00 A.M., EST, on the 4th, and the moon passes both between midnight and 1:00 A.M. on the 5th.

October 7: Jupiter is near the crescent moon early this morning.

October 12: Mars is well below the crescent moon until it sets.

October 21: Tonight (from 1:00 A.M. on) is best for hunting the Orionid meteors, about 25 per hour, but swift and often bright.

October 24: Mars and Antares (the bright red star of Scorpius) are in conjunction. Both are low in the southwest at dusk.

October 26: Communities on daylight time set clocks back one hour early this morning.

October 30–31: Be sure to look for Venus (the brighter) and Jupiter on both mornings, in the east at dawn. Venus passes Jupiter at about 3:00 P.M., EST, on the 30th. Saturn is below the two.

November 1–4: Try to watch the eastern dawn sky each morning these days, to see Venus move between Jupiter and Saturn, and the crescent moon pass Regulus, Jupiter, Saturn, and Venus in turn.

November 11: Mercury resumes its direct (easterly) motion as a morning star.

November 15–16: This is the night (from 1:00 A.M. on) for the Leonid meteors, the swiftest, brightest, and most famous of all meteors.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you face the other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the evening sky at about 11 to 12 P.M. on October 1; 10 to 11 P.M. on October 15; 9 to 10 P.M. on October 31; and 8 to 9 P.M. on November 15. It shows only planets and moon phases above the horizon at those times.

# Little Finger Nail's Ledger Book

On display in the Hall of Plains Indians at the American Museum of Natural History is a ledger book covered with faded bloodstains. It has been pierced by a bullet that tore through its cover and shredded some of its pages. Inside are scenes of battle and courtship drawn by Little Finger Nail, a young Northern Cheyenne warrior, during the last months of his life.

This ledger was one of two given to the Museum in 1912 by the estate of Joseph Cuyler Hardie. Hardie's brother Francis, a cavalry officer during the Indian wars, had taken the bullet-pierced ledger from the body of Little Finger Nail following a battle. He sent the two ledgers to his brother with the following letter:

> Post of San Antonio, Texas
> Sept. 21, 1889
>
> Only the canvas covered book has any special history, the book with the bullet hole in it. It was, or rather the pictures were, drawn by a Northern Cheyenne Indian while in confinement at Fort Robinson, Nebraska during the winter of '78, '79. I was then Post Adjutant. I endeavored to get the book but its owner and maker refused to part with it for any price. So I gave the matter up. It purports to depict the deeds of several of the Northern Cheyennes during their famous march from the Indian Territory to Wyoming Territory. The outbreak of the Cheyennes is well known, and [as] a consequence of the outbreak, I got the book in this manner. Four troops . . . commanded by Captain Wessells, who by the way was severely wounded, surrounded the hostiles and charged upon them killing all the bucks and unfortunately in the melee, some women and children, but previous to the charge I saw an Indian with the book pressed down between his naked skin and a strap around his waist; another strap went between the middle of the book and around his shoulder. I turned to Private Laselle of H troop who was near me and said, "I want that book if we come out all right." Several others of the enlisted men heard me also. When the fight was over, and as the dead Indians were being pulled out of the rifle pit, they drew out finally my Indian with the book, apparently dead; the book was injured to the extent of a carbine ball through it and was more or less covered with fresh blood. This fight took place near Bluff Station, Wyoming Territory, January 22, 1879. This fight was the closing one of a series of fights with the Indians, and they perished to a man.
>
> In haste,
> Frank [Francis H. Hardie]

Ledger-book Indian art was not uncommon during the closing years of the Indian Wars. It supplanted to some degree earlier warrior art, which detailed the exploits of the warrior and his friends in paintings on the flesh side of buffalo hides and tepee covers. Ledger books, convenient and portable, could be carried into battle and were not likely to be destroyed by soldiers who often burned villages after surprise attacks.

Some warriors painted their own scenes, but more often a warrior would

ask an artist in the tribe to outline the figures in paint, which the warrior would then color in. He would recount to the artist various incidents in his life, including details of specific battles—descriptions of horses, the number of troops, even the brands on captured horses and cattle. Early warrior art used paints made from ash mixed with buffalo blood (for black), or from different iron-bearing clays mixed with the gluey residue of hide scrapings (for colors). Pencils, crayons, ink, and watercolors obtained from traders quickly replaced the traditional paints.

The story of Little Finger Nail's ledger begins with the Northern Cheyenne's disastrous defeat at their camp on Crazy Woman's Fork on the Powder River. Gen. Ranald Mackenzie and his soldiers drove the survivors, including two great chiefs, Dull Knife (Morning Star) and Little Wolf, deep into the Bighorn Mountains. Suffering from frostbite and starvation after a bad winter in the mountains, the Cheyenne voluntarily surrendered at Fort Robinson in April, 1877.

They were at Fort Robinson for only a short time when the U.S. government, acting under the terms of a treaty the Cheyenne had signed in 1868 with General Sheridan, ordered the band moved south to Indian Territory. Outraged, Dull Knife and the other chiefs claimed that Sheridan must have lied to them about the terms of the treaty. Finally, under extreme pressure and with the promise that they could return if they didn't like the South, the Cheyenne acquiesced.

In August 1877, Dull Knife, Little Wolf, and their people arrived at the Darlington Agency, near Fort Reno, Indian Territory. Almost immediately, two-thirds of the tribe came down with malaria and other diseases. The water was bad and rations were scarce and foul. (Even Mackenzie protested to Washington, referring to the terrible conditions on the reservation as "starvation" and a "great wrong.") The Cheyenne told agent John D. Miles:

> We are sickly and dying here, and no one will speak our names when we are gone. We will go north at all hazards, and if we die in battle our names will be remembered and cherished by all our people.

At dawn on September 9, 1878, many of the Cheyenne, led by Dull Knife and Little Wolf, left the reservation and headed north. Thus began the famous Cheyenne march from Indian Territory to Wyoming Terri-

tory—and also the events that Little Finger Nail recorded in his ledger.

Little Wolf, who had been fighting white men since 1856, warned his people, especially the young warriors such as Little Finger Nail, that they were not to fire at soldiers unless fired upon, and on no account were they to kill settlers or cowboys.

As they moved north, the Cheyenne were attacked again and again by soldiers. They fought them off when they could and retreated when they were outnumbered.

As they neared Dodge City, on the open Kansas prairie, they were again attacked, this time by soldiers and cowboys. Although the Cheyenne repulsed their attackers, Little Finger Nail and the other young warriors were angry and vengeful. Tired of restraint and in need of horses and food, they no longer listened to Little Wolf. The next day, some of them raided a cow camp, killed four whites, and captured some horses and mules. They continued to raid settlements north of Dodge City, especially along Sappa and Beaver creeks, where buffalo hunters and soldiers had massacred Cheyenne women and children thre years before. In retaliation for thos killings, Little Finger Nail and hi friends shot exactly as many whit men as the whites had killed India men. And in one raid, they capture more than 200 horses.

Little Finger Nail recorded man of these events in his ledger book Some scenes depict the raids and th frequent encounters with troops: w see drawings of a warrior gallopin through a hail of bullets, a young ma on a spotted horse counting coup o a fallen settler, a camp of buffalo hunters, a smiling warrior galloping of with stolen U.S. Cavalry horses, an a major battle with entrenched soldiers (possibly one of several nea Dodge City). We know that most o the warriors are young because thei clothing is unadorned and their shirt are of white manufacture. Scattere among the battles and raids are scene of love and courtship.

The second ledger, drawn by an unknown Indian, probably records th same raids, and even includes th name glyphs of the warriors involved Our only clue to who created this sec

**Film Festival**

On Saturday and Sunday, October 4 and 5, the 1980 Margaret Mead Film Festival will feature ethnographic films and discussions with filmmakers and anthropologists. Special programs in this year's festival include premières of four films on the People's Republic of China and films and discussions on Iran. Weekend programs are free, and film schedules may be picked up at Museum entrances. (See "At the American Museum" in last month's *Natural History* for details.)

**Witches, Goblins, and Ghosts**

To mark Halloween, storytellers Laura Simms, Jackie Torrence, and others will spin tales of ghosts, demons, and a host of supernatural beings from around the world—from Asia and Africa to the deep South. The program, which is free to members, $3.00 for nonmembers, will be presented in the Education Hall on Sunday, October 26, at 11:00 A.M., 1:30 P.M. and 3:30 P.M.

**Classical Indian Dance**

Indrani and her daughter Sukanya will perform classical Indian dances in the Auditorium on Wednesday, October 29, at 7:00 P.M. The free program includes selections from two of the major traditions, Bharata Natyam and Orissi.

**Asia Live**

Live programs and lecture-demonstrations of dance, music, and crafts of Asia will be presented in the People Center on weekends in October and November. On October 18 and 19, India is the featured country, and on October 25 and 26 and November 1 and 2, Japan.

**Asia on Film**

On October 18 and 19, four films on India will be shown in the Auditorium from 2:00 to 4:00 P.M., including *Kishan and the Magic Chariot*, about a boy and his schoolmaster, and *From the Ocean to the Sky*, about adventurers who journey up the Ganges by jet boat. On October 25 and 26, *Full Moon Lunch* and *Farm Song*, two John Nathan films that look at two different sides of traditional Japan, will be screened. All films are free.

**Books on Asia**

An exhibit of books, some quite rare, used to research and design the new Gardner D. Stout Hall of Asian Peoples, ond ledger is the frequent repetition of a name glyph that looks like a humpbacked buffalo, and we know that one of the young Cheyenne was called Bull Hump.

After crossing the South Platte River on October 4, 1878, Little Wolf and Dull Knife disagreed on where to proceed. Dull Knife wanted to go to the Red Cloud Agency where he thought the Sioux were. Little Finger Nail and part of the band joined him, while Little Wolf headed north.

On October 23, Dull Knife's band was surprised by soldiers during a blinding snowstorm and taken to Fort Robinson. Along the way, they took apart their best rifles and pistols and hid the pieces among the clothes of the women and children.

At Fort Robinson the Cheyenne had a lot of free time and were given the run of the camp. Here Little Finger Nail drew many, if not all, of the scenes in his ledger; the other ledger was probably also created at this time.

All went well until the soldiers discovered that Bull Hump was missing. The Cheyenne were immediately confined to their barracks, and remained

will be on display in the Library Gallery beginning in mid-October.

**The Planets**

*The Planets*, an exhibit of the gold- and silver-wire designs of Raoul Lametz, opens at the Hayden Planetarium on October 1. This artist has incorporated astrological symbolism and scientific data in his renderings of the various planets of the solar system.

**Discovery Tours**

Thomas D. Nicholson, director of the Museum, and six other Museum and guest lecturers will lead a cruise of the waterways of western Europe in late June 1981. Major land excursions will explore Barcelona, Granada, Seville, Lisbon, Santiago de Compostela, La Rochelle, Brest, Mont St. Michel, and Rouen. This is the sixth Museum cruise aboard the m.t.s. *Orpheus*, arranged with Swan Hellenic Travel of London. Other cruises have visited the Black Sea, the Adriatic, the Mediterranean and North Africa, and Egypt and Israel. Nicholson, with Swan, has created a new itinerary that will visit archeological sites, zoological sanctuaries, and other places of interest. For information on the 1981 Museum travel program, write to Discovery Tours at the Museum.

*For the eighth year, we invite you to witness North America's greatest wildlife spectacle:*

The Seals on the Icepack

MARCH 1 TO 6, AND 5 TO 10, 1981

Each year, thousands of seals end their migration in Canada's Gulf of St. Lawrence and congregate on the icepack, turning it into a huge natural nursery as the females give birth to their babies.

We are the only company in the world with the experience, knowledge and audacity to offer these unique, thrilling and exhilarating tours.

*Detailed brochures of the tours and a copy of our newsletter which lists all our fascinating travel programs, available from:*

prisoners even after Bull Hump returned a few days later. Meanwhile, Capt. Henry Wessells, the commanding officer, received orders that the Cheyenne were to be sent south immediately. When Dull Knife heard this, he said:

> All we ask is to be allowed to live, and to live in peace. I seek no war with anyone. An old man, my fighting days are done. We bowed to the will of the Great Father and went far into the south where he told us to go. There we found a Cheyenne cannot live. . . . To stay there meant all of us would die. . . . We thought it better to die fighting to regain our old homes than to perish of sickness. Then our march was begun. You know the rest.
>
> Tell the Great Father that Dull Knife and his people ask only to end their days here in the north where they were born. Tell him we want no more war. . . . Tell him if he tries to send us back we will butcher each other with our own knives. I have spoken.

Wessells relayed Dull Knife's message to Washington and received the following reply from General Sheridan: "Unless they are sent back to where they came from, the whole reservation system will receive a shock which will endanger its stability." When Dull Knife was told of Sheridan's response, he said: "Great Grandfather sends us death in that letter. You will have to kill us and take our bodies back down that trail. We will not go."

Wessells responded by cutting off all food, fuel, and water to the Indians locked in the barracks. A few days later, on January 8, 1879, the Cheyenne covered the windows of the barracks with blankets, ripped up the floorboards to make clubs, and assembled twelve rifles and three pistols from the pieces they had previously hidden. Thinking something might be up, Wessells increased the guard and had a blacksmith wrap chains across the locked doors. During the evening of January 9, the Cheyenne put on their war clothes and painted their faces. Little Finger Nail strapped his ledger around his waist and secured it with a second strap that passed through the middle of the book and around his shoulder.

At 9:45 P.M., Little Finger Nail and another young leader smashed two windows and started shooting, killing the sentries at the southwest and western ends of the barracks. Within seconds, the other warriors opened fire on the guards. Men, women, and children began pouring through the broken windows. As the Cheyenne fled across the snow-covered prairie in the bright moonlight, the soldiers piled out of their quarters and fired away at the fleeing figures, killing about half, including some of the slower women and children. Wessells sent the cavalry in pursuit of the rest.

Little Finger Nail and a small band

*This drawing in Little Finger Nail's ledger book shows a warrior attacking a soldier. Damage, at right, was caused by a bullet.*

of people made it across the White River and headed southwest into a series of bluffs behind the camp, then veered northwest. They had no horses, little food, and scant clothing. During the days that followed, the Cheyenne tried to shake the soldiers from their trail, with no success.

Finally, thirteen days after the escape and only thirty-five miles from Fort Robinson, they realized that escape was hopeless and decided to dig in to meet the soldiers in battle. Uncharacteristically, they chose a poor defensive position—a dry streambed at the edge of the bluffs. The soldiers had a clear line of fire, and the Cheyenne did little to conceal their presence, although they did pile up frozen sod and try to chip out rifle pits in the earth.

The pursuing soldiers, Frank Hardie among them, quickly discovered the hide-out. As Hardie mentions in his letter, he was close enough to pick out Little Finger Nail before the battle. The cavalry charged to the edge of the washout again and again, firing into the scattered shrubbery, the rifle pits, and the crude breastworks that hid the Cheyenne. For an hour, the vastly outnumbered Indians—thirty-one men, women, and children—fought with the few guns and ammunition they had. When all was silent, Wessells and the troops moved up the edge of the washout and gazed at the bodies scattered about. Suddenly, a warrior raised his gun and fired at the captain, hitting him in the head. The soldiers immediately resumed the attack. After firing at the bodies in the hollow for about fifteen minutes, they again paused, but within moments three bloody warriors leaped up and armed with only two knives, charged the soldiers. The soldiers promptly shot them down.

Once more the nervous soldiers crept to the edge of the washout. Only a few women and children were alive; most were badly wounded.

When the soldiers had hauled the last of the bodies from the washout, Hardie untied the ledger book from Little Finger Nail's body. He carried it with him for ten years until 1889, when he sent it east to his brother. The Museum, which received the ledger in 1912, put it on display in the Hall of Plains Indians in 1934. It remains there today, a Cheyenne warrior's account of the last days of his people.

# Additional Reading

**Moose** (p. 38)

D. Allen's *Wolves of Minong: Their Vital Role in a Wild Community* (Boston: Houghton Mifflin Co., 1979), a semitechnical treatment of the classic Isle Royale moose–wolf study, includes information about moose behavior and ecology. A classic in the field, E. O. Wilson's *Sociobiology: The New Synthesis* (Cambridge: Harvard University Press, 1975) treats animal behavior from one sociobiological perspective. Discussion of the multiple equilibria/catastrophe theory and a review of new ideas and applications of systems ecology can be found in *Adaptive Environmental Assessment and Management*, edited by C. S. Holling (New York: John Wiley and Sons, 1978). E. C. Zeeman introduces catastrophe theory in an article in the April 1976 issue of *Scientific American*, pp. 65–83, and presents the subject more thoroughly in *Catastrophe Theory: Selected Papers (1972–1977)* (Reading: Addison-Wesley Publishing Co., Inc., 1977).

**Opium Poppy** (p. 52)

Although most available literature on the opium poppy deals mainly with social aspects of the plant as a source of opium and opium derivatives, the United Nations Division of Narcotic Drugs (Vienna International Center, P. O. Box 500, A-1400, Vienna, Austria) publishes material on nonnarcotic uses of the poppy, which they will furnish to people who write for it. The June 1950 issue of their *Bulletin on Narcotics* (vol. 2, no. 1, pp. 13–25) contains a detailed description of the cultivation of the plant in Turkey as practiced before the 1971–74 ban. "A Survey on the Factors Preventing Opium Use by Poppy Growing Peasants in Turkey," by Alâeddin Akcasu (vol. 28, no. 2, 1976, pp. 13–17), explores the phenomenon of opium avoidance in rural Turkey. The Division's pamphlet, *The United Nations and Drug Abuse Control* (1976), summarizes the development of the international drug control system.

**Stromatolites** (p. 58)

*Stromatolites* ("Developments in Sedimentology 20"), edited by M. R. Walter (New York: Elsevier Scientific Publishing Co., 1976), is a collection of articles explaining the present and past distributions of stromatolites and their morphogenesis, with a complete bibliography. This book includes "Modern Algal Stromatolites at Hamelin Pool, a Hypersaline Barred Basin in Shark Bay, Western Australia," by P. E. Playford and A. E. Cockbain and "Stromatolite Morphogenesis in Shark Bay, Western Australia," by P. Hoffman.

**Anteaters** (p. 62)

Two of G. Durrell's books describe his encounters with giant and pygmy anteaters. *Three Tickets to Adventure* (New York: The Viking Press, 1955), a record of the author's animal-collecting trip to British Guiana (Guyana) in 1955, includes photographs of anteaters. One chapter of *The Drunken Forest* (New York: Penguin Books, 1958) describes the adventures of Durrell and his wife in rearing a baby giant anteater. For a scientific account of anteaters, see "Prey Influences on Movements of Neotropical Anteaters," by G.G. Montgomery and Y.D. Lubin in *Proceedings of the 1975 Predator Symposium*, edited by R.L. Phillips and C. Jonkel (Missoula: University of Montana, 1977). G. Montgomery is currently editing a comprehensive book on the biology of the Xenarthra to be published by the Smithsonian Institution Press.

**Indian Photos** (p. 68)

R.B. Hassrick's *The George Catlin Book of American Indians* (New York: Watson-Guptill Publications, 1977) contains reproductions of nearly half of Catlin's American Indian paintings. J. Ewers analyzes Catlin's work and that of others in "George Catlin, Painter of Indians" (*Smithsonian Annual Report for 1955*, pp. 483–528). J. Scherer discusses photography of American Indians in *Indians: The Great Photographs That Reveal North American Indian Life 1847–1929, from the Unique Collection of the Smithsonian Institution* (New York: Crown Publishers, Inc., 1974) and in "You Can't Believe Your Eyes: Inaccuracies in Photographs of North American Indians" (*Studies in the Anthropology of Visual Communication*, Fall 1975, pp. 67–79).

# Soviet Intervention

**by David E. Powell**

THE DESTRUCTION OF NATURE IN THE SOVIET UNION, by Boris Komarov. *M.E. Sharpe, Inc., $15.00; 160 pp.*

This is an extraordinary book. Its author, identified only as "a ministry official who continues to live in the Soviet Union," demonstrates a breadth of knowledge so vast, a sense of moral outrage so profound, and a gift for language so acute as to make *The Destruction of Nature in the Soviet Union* a landmark in our understanding of environmental problems in the USSR.

Readers of *Natural History* are doubtless aware of the damage already done to Lake Baikal in Siberia, and some may even know about the threatened extinction of certain species of animals found only in the most remote corners of that country. But few readers are likely to be informed about the extent of environmental degradation in the USSR, and fewer still have had access to information about the political, economic, and ideological factors that have given rise to this tragic state of affairs.

To be sure, there are now a fair number of English-language books and articles devoted to environmental problems in the USSR: studies by Keith Bush, Cynthia Enloe, Marshall Goldman, Donald Kelley, John Kramer, Philip Pryde, and Fred Singleton. Until the publication of this book, however, no Soviet author had put together a comprehensive study of air and water pollution, land depletion, and the destruction of wilderness and wildlife in that nation. We are in debt to Mr. Komarov (a pseudonym, of course, since this is a *samizdat* work). He has been well served by his translator, who is faithful to the style and tone of the original—somewhat rambling, often witty, and always impassioned. Marshall Goldman has added a brief, but useful, introduction.

While Western specialists on the USSR will be uneasy because only some of what Komarov says is documented, his general argument has the clear ring of authenticity. It is also consistent with what I (and others) have learned from Soviet scholars, journals, and other Soviet sources.

Komarov devotes two chapters to environmental disruption in Siberia. One chapter focuses on the Baikal episode, describing the "moral," as well as the ecological, harm associated with the construction of two huge pulp and paper combines on the lake's shores. The author speaks eloquently about "the deadly peril that is accumulating gradually and silently, like an avalanche, in the depths of Baikal." Purification equipment, belatedly installed after expressions of outrage were heard from Soviet scientists and concerned citizens abroad, works poorly and has only slowed the pace at which damage is occurring. In Komarov's words, "it merely transformed wholesale pollution into pollution of Baikal in installments."

He is appropriately critical of prominent scientists who were willing to go along with this shortsighted policy, men who rationalized their decisions in the most crude and cavalier manner. Consider, for example, A.P. Vinogradov, the vice-president of the USSR Academy of Sciences, who summarily rejected a report by a panel of experts recommending that the project be abandoned. "You mention that the Baikal combines will prove fatal to the lake," he declared. "But how can this be? The government decides to build, and you say 'impossible. . . .' Take your report and do some more work on it." The argument of a second academician was even more primitive. "Why are we going on so about this Baikal?" he asked. "Pollute it if we have to. Now we have nuclear energy, and if later we have to, we can easily make Baikal again." (It should be noted that the damage to Baikal did not end with the construction of the two plants. The Baikal-Amur mainline being constructed in Siberia has already added to the lake's distress and will do even more harm in the future. According to Komarov, "Gasoline, diesel fuel, grease, and other petroleum products from every settlement's workshops, garages, and railroad car depots gather drop by drop, trickle by trickle, stream by stream into a constant, black petroleum tributary of Baikal.")

Other parts of Siberia have also sustained environmental damage on a scale that can only be termed "Siberian." For many kilometers around villages, Komarov reports, "there is neither a tree nor even a bit of natural landscape—only littered, swampy wasteland where heaps of ash, slag, bottles, other rubbish, and the hulks of cars and trucks abound." Furthermore, because so much energy is used to heat modern apartments in this frozen land, the air above many settlements has been "gravely affected," and nearby territories suffer even greater harm. "Ten months of smoky atmosphere, filthy snow, and dirty meltwater kill all the moss and lichen in the surrounding area. . . . Deprived of its covering . . . the permafrost quickly turns into swamp."

Other chapters offer no more grounds for optimism. In the chapter that deals with air pollution, for example, readers will learn about the Soviet city that has had to set up a special brigade of workers to clear away, every three months, the dirt and soot that accumulate on rooftops throughout the city. (If this step were not taken, the roofs would collapse.) In addition, the air over the Siberian city of Bratsk regularly contains levels of carbon monoxide, sulfur dioxide, and other gases far above those considered safe. As a result, "the taiga around Bratsk, to say nothing of the green areas within the town limits, is rapidly withering. One hundred percent of the seedlings are dying."

A chapter on water pollution focuses on PCBs, petrochemical wastes, DDT, heavy metals (such as mercury, cadmium, and lead), and other substances familiar to American environmentalists. Komarov notes that the Sea of Azov, once "famed for its fantastic catches of sturgeon, carp and perch," has become "a latrine . . . for the industrial south of Russia and the Ukraine." He compares the damage to Azov with that to Lake Erie in the United States. "Here, at Azov, we have caught up with America. And gone ahead, since Erie was never the nation's marine larder, as was Azov." Some rivers, he also notes, "have been turned into sewers."

Komarov's account of the wanton destruction of wildlife in the USSR is especially depressing. As readers of the Soviet press know, the country's nature preserves, where wildlife is supposedly protected and hunting strictly forbidden, are regularly violated by Communist Party, government, and military officials—"the very pillars of society," as Komarov contemptuously calls them. There is a chilling description of a hunt in the Kyzyl-Agach Preserve in Azerbaijan organized by Marshal Chuikov and his fellow officers. "Early in the morning the marshal, his adjutants, and the entourage drove onto the preserve in a whole column of all-terrain vehicles." After shooting hundreds of ducks, geese, and other birds, Chuikov transferred to a helicopter: ". . . circling over the reed banks and spotting a herd of wild boar, he began shooting at them with his automatic rifle."

Even more grotesque is the training technique developed by military officers stationed in the Baikal area. For many years, they have given their men practice in the use of ground-to-ground, heat-seeking missiles by having them fire at wild boar and deer on the run. "Startled by the sound of a shot, the animals dash across wooded hills, and the accurate rockets overtake them wherever they go."

*The Destruction of Nature in the Soviet Union* is obviously the product of careful research; it combines the virtues of "insider" reporting, serious reflection, and vigorous scientific analysis. At the same time, it is a *cri de coeur*, a passionate statement of protest by a man who loves his country, who is deeply moved by its natural beauty and proud of its abundant resources but horrified at what the government has done in the name of "progress," "military security" and "the national interest."

He expresses particular anger at the dishonesty of official propaganda, which blandly denies the possibility of any serious threat to the environment in a "socialist" state. "To create the illusion that existing economic and ideological means are sufficient to deal with the problems of ecological disaster, or that the current course of the economy can steer the country away from the reefs and shoals toward which other countries are drifting," he writes, "is the gravest sin of Soviet propaganda. A sin unforgivable in its consciousness and premeditation."

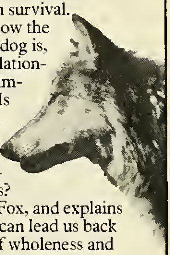
One can only be saddened by all this, for the Soviet leadership has wasted a golden opportunity to preserve and enhance nature's gifts. The USSR is less advanced economically than the West and thus can profit from our mistakes. The Soviet political elite claims to be guided by the lofty ideals of "socialist humanism." The State owns all the land and the means of production, and the Communist Party can impose its will on all individuals and organizations throughout the country. In view of these circumstances, we might have expected the USSR to be safe from the depredations of "robber-baron" industrialists and other despoilers of nature.

However, as the Soviet experience demonstrates, centralized decision making and the capacity to mobilize the energies of the entire population have not always led to socially desirable ends. Socialist industrialists, no less than their capitalist counterparts, have shown themselves capable of despoliation on a massive scale. Indeed, centrally determined priorities, allocations, incentives, rewards, and punishments have been harnessed to an almost pathological fixation on production, at the expense of all else. Today, ecological concerns remain a "luxury" that the Soviet leaders—like their counterparts almost everywhere in the "civilized" world—simply cannot understand.

*David E. Powell is a research fellow at the Russian Research Center and a lecturer on government, both at Harvard University.*

**An intelligent society, ruled by love, in harmony with nature...**

The wolf pack is an extended family with responsible leadership, social order, loyalty, love, nurturing. At last human beings are beginning to explore and understand its secrets. Michael W. Fox, veterinarian author of *Between Animals and Men* and other acclaimed books, offers a provocative meditation on wolves and what they can teach us about our own survival.



He shows how the domesticated dog is, in its social relationships, like an immature wolf. Is civilized man, by analogy, less mature than his primitive ancestors? Yes, answers Fox, and explains how the wolf can lead us back to the sense of wholeness and oneness with nature that we have lost.

"Uncanny in its insights—eye communication, control of aggressive impulses, social climbers, the 'executive personality.'...A provocative and rather awesome tribute to our animal brothers."

# Fleece Afoot

*Herds of sheep grow fat on the cool green grasses above timberline*

**by Raymond Sokolov**

Way back up in the hills, high above the Colorado River, high above the tourists in rafts and kayaks, but less than fifty road miles from Doc Holiday's Bar in Glenwood Springs, with its Old West trappings and mean-mouthed barmaid, you get to the top of an anonymous mountain in the White River National Forest and turn left through the aspens and Engelmann spruces onto a dirt track they call the Bar H-L Road. You'd better go in with a four-wheel drive, because when it rains, the gradually descending trail, marked with U.S. Department of Agriculture Forest Service mileposts, can turn to quagmire. On a dry day in early July, maybe ten miles after the turn and just as you are getting used to the bumping ride and the lush, fabulously expansive meadows, spattered with flowers and empty against the big sky, you hear the noise, as loud as a city of untuned bells or a jungle of monkeys.

Five thousand sheep are on the march up to their summer pasture where the grass stays cool and green. They are heading along an official stock driveway, through cattle-grazing country to higher pasture where only sheep can survive, for a two-month session of nomadic fattening. Ewes and lambs bleat as they walk—mothers trying to find their babies, babies separated from their mothers calling out, and eventually, since each animal has its own special bleat, they locate each other, bounding through the flock and then, always moving, the lambs "mother up" joyfully on the ewes' teats. The flock trudges on, guided by instinct but also shooed forward by shepherds on horseback and little dogs that keep the sheep from straying off into the woods. The herders whistle and hoot and head off the ragged edges of this woolly white mob. The flock flows over the tan road like a huge, low cloud.

Idyllic? Why of course it is. Theocritus coined the word *idyll* for his bucolic poems, which for the first time in Western literature described just such a scene. All pastoral poetry hymns the life of the shepherd (Latin *pastor*). And this procession of lonely men and gregarious animals (Latin *grex*="herd") from low pasture to high, this transhumance, is older than literature, older even than settled agriculture and the sedentary life we call civilization. But even the ancient tradition of the pastoral contained a darker strain, epitomized by the famous Latin tomb inscription that crops up in pastoral paintings by Guercino, Poussin, and Reynolds: *Et in Arcadia ego*, "Even I [death] am in Arcadia," the mountainous traditional haunt of Greek shepherds in the Peloponnesus.

And even in late twentieth-century Colorado, mortality lurks behind the peaceful and picturesque surface of the annual sheep drive. Nobody knows this better than Gus Halandras, whose survival as a sheepman is threatened by forces far more complex than the natural risks that menaced the pastoral livelihood of his Greek ancestors Thyrsis and Corydon in Arcadia.

On the surface, Halandras and his five thousand sheep are doing fine. He and his wife, Christine, both of them children of Greek immigrants, live in a big house in Meeker, Colorado, and raise fat sheep on open rangeland. But like all other American sheep producers, the Halandrases o erate in what might be called a hostil environment. The statistics are el quent.

In 1979, the national sheep floc numbered 12.5 million animals, mere fifth its peak size of 56 millio in 1942 and only a quarter what th flock was at the time of the first U.S sheep census in 1867, when the huma population was under 40 million. Las year's lamb slaughter yielded only 29 million pounds or 1.6 pounds per pe son. Compare this to an annual bee gorge of 120 pounds per capita an you have to conclude that lamb i relatively speaking, an endangere species.

Ironically, in the eleven wester states where 60 percent of America' sheep are raised, mostly on open range virtually no lamb is consumed. Th South is also a desert for lamb. Two thirds of American lamb is shippe to the Northeast, half of that to th New York City metropolitan marke where people of Mediterranean an Jewish background persist in buckin the national trend toward an all-bee meat diet. Gus Halandras says tha 90 percent of his lamb goes East.

No one, however, can say for sur why Americans don't all love lam with the fervor of Greeks and Jews Halandras speculates that a whol generation of GIs were subjected t bad Australian mutton during Worl War II and afterward wouldn't touc so much as a lamb chop. Then ther is the fact that beef cattle were con venient machines for gobbling up th postwar grain surplus and turning i into cheap, easy to prepare meat, whil most sheep continued to eat plai

# "At Gulf, we're working on a way to light lights, cook meals, and heat houses with the energy stored in water."

"You probably remember from grade-school science that water is two parts hydrogen and one part oxygen," says Dr. John Norman.

"Here at General Atomic Company, a subsidiary 50% owned by Gulf Oil, a project is under way to extract hydrogen from water for use as a fuel: for heating, cooking, or anything that now uses petroleum or natural gas.

*"There are 326 million cubic miles of water on earth, and hydrogen in every drop–a natural energy resource that won't run out."*

"The extraction process is called thermochemical water-splitting. We know it works because we've done it. But it takes high temperatures – about 1600° F – so it's rather expensive.

"It may be the turn of the century before it becomes commercial. But it's an attractive idea. Hydrogen from a gallon of water has about half as much energy as there is in a gallon of gasoline.

"Hydrogen can be made into a liquid or gaseous fuel. It can be transmitted long distances more cheaply than electricity. And when hydrogen burns, it's converted back into water. Very tidy."

At Gulf, our first priority is to get all the oil and natural gas we can out of resources right here in America. But we're working on a lot of other ideas, too. Thermochemical water-splitting is one of them. We are also working on underground coal gasification, solar research, liquefied coal and other synthetic fuels, geothermal energy, and other alternative energy sources.

Basically the business we are in is energy for tomorrow.

Gulf

**Gulf people: energy for tomorrow.**

Gulf Oil Corporation

grass. Not only that; Americans who did indulge in lamb limited their consumption to the most expensive cuts, the chops and the leg. As a result, lamb has an expensive image, although these days the average price "across the carcass" is running about $2.50 per pound, as compared with $2.33 for beef.

To help educate the American consumer about efficient use of the whole lamb in cooking, Christine Halandras recently compiled a booklet of recipes for the American Sheep Producers Council (see recipes below). She is a skillful advocate of lamb consumption from tripe to head and has even taken to preparing Rocky Mountain oysters (lamb testicles) in an ingenious if improbable modern manner. Oysters are normally very hard work to clean, but as delicate as sweetbreads when breaded and fried. Mrs. Halandras drops them in her garbage disposal, which miraculously removes the tenacious mucous coating and leaves a perfectly white and unharmed oyster.

On the trail, she cooks more conventionally, but with a practical brilliance that made me think of pioneer women improvising meals out of their Conestoga wagons. In fact, the home economics of cooking for thirteen people in a modern sheep camp are not too different from pioneer conditions. For five days on the trail, the Halandras family, their two herders, and their guests all live in two tents and two metal-clad, homemade vehicles called sheep camps. Jim Atencio and Tomás Magaño, the herders, normally live by themselves in the camps, which look like gypsy wagons with stovepipes coming out of the roofs. Years ago, the ancestors of today's camps had long-spoked wooden wheels and were pulled by horses. In our time, pickup trucks do the hauling and the camps roll on inflated rubber tires. Otherwise, inside the camps, history stands still.

Ingeniously fitted out with wood bunks and a slide-out tabletop, as well as cupboards and stowage compartments, the Halandras camps reminded me of ships' cabins. The kitchen area, near the doorway, centers on a cast-iron wood stove, fired by fallen timber picked up along the way. On its surface and in its little oven, Christine Halandras managed to turn out impeccable pancakes, hot biscuits, and eggs with chopped venison. One day, she made a lamb stew from "rough cuts" that Gus Halandras sliced off the partly butchered yearling lamb he had slaughtered just before they left. The meat kept remarkably well in an unrefrigerated screened box. Year-old lamb is technically mutton, but this meat was tender and very flavorful, not muttony. The stew simmered during the midday break and then had to be hauled inside the camp to the place where we were going to spend the night. To keep the stew from spilling, Mrs. Halandras put the pot in a big metal washbasin. Barely a drop splashed out along the way.

On another night, we ate wheat tacos rolled out that afternoon by the Mexican herder, Tomás, and filled with venison chili. And at every meal, there was something produced in Christine Halandras's canning kitchen back in Meeker, where she puts up two thousand jars of spicy pickles and peach jam and tomatoes in a good year. At breakfast, for instance, she brought out some cherry syrup, a sweet-and-sour concoction she makes from the juice left in the large containers of pitted cherries she buys from a ladies aid society.

The whole family collaborated on these meals, feeding the stove, chopping, and peeling. Gus Halandras turned out to be a mean egg fryer, and his smoked mutton, sliced for an afternoon snack, was as sophisticated a use of a normally maligned meat as you could imagine.

All this cooking takes place in the middle of the day, while the sheep are grazing, waxing fat and not exerting themselves in the full sun. The herders rouse them at 5:00 A.M., while it is still cool, nudging the flock from behind to get the animals moving in the right direction, herding them along the road for a couple of miles or so, then resting them until 4:00 P.M., when they move them on for a similar distance and then stop them for the night. The pace is slow and orderly, to save the sheep's energy and prevent injury or loss. And all the way along the Bar H-L Road—which follows the migrational path of earlier nomads, the Ute Indians—other flocks belonging to other ranchers are ambling, in a federally controlled order of march, up to their grazing allotments on Forest Service lands.

This system was set up by the Taylor Grazing Act of 1934, which established firm official control of grazing on public lands. The Forest Service now regulates which sheep go where and when, in order to eliminate trampling of pastures still wet from spring runoff and to prevent the overgrazing that once exacerbated the traditional enmity between cattle and sheep producers all over the West.

Plenty of grassland is required in rough country above eight thousand feet to pasture sheep adequately. In the old days, free-ranging herds left wastelands behind them and earned the name "hoofed locusts" from cattlemen who retaliated by shooting whole flocks or driving them off cliffs. Under the modern system, which he finds overregulated and costly, Gus Halandras pays $2,700 for grazing rights on twenty thousand acres of USDA forestlands in the summer. In the winter, he uses sixty to seventy thousand acres of desert controlled by the Department of the Interior's Bureau of Land Management. Halandras has been driving sheep to these pastures for thirty years, and before him, his father had the same allotments. Understandably, he feels possessive about the vast meadows and resentful when bureaucrats regiment his drive.

photograph by Adelaide De Menil

Federal regulation is a rich topic of embittered discussion at the Halandras camp during the leisurely middays of the drive. Not only do the authorities control grazing, they also hinder Halandras's ability to import experienced herders. At the moment he has the men he needs. Jim is a U.S. citizen and Tomás has a green card that permits him to come in legally from Mexico to work most of the year in complete isolation, thousands of miles from his wife and children in the state of Michoacán. Few Americans are willing to endure a shepherd's solitude and fewer have the training necessary to supervise sheep. And the immigration laws are a roadblock in the way of sheep producers who want to import experienced shepherds on a permanent basis.

From Halandras's point of view, an even more galling threat to his kind of traditional mountain grazing comes from environmentalists who, at their most radical, want to keep sheep out of public lands altogether, protecting the fragile alpine ecology from everything human except perhaps a controlled form of tourism. "What could be more sensible, environmentally, then open range grazing?" he asks, while loading four orphan "bum" lambs, which have to be bottle-fed, into his overloaded pickup. "It takes no grain, no supplementals. We produce prime meat with grass feed. Is this country so affluent it can abandon a renewable resource and keep it just for recreation?"

Later, after a bath in a stream, Halandras fulminates some more against meddling wildlife preservationists who don't share his hatred of the coyote. Like other sheep producers, Halandras would like to use poison to control the coyotes, which, according to him, kill 10 to 15 percent of his lambs. But since 1972, when President Nixon ordered a ban on predator poisons on public lands, sheepmen have had to depend on traps, guns, and guard dogs. Last year, Jim Atencio did manage to trap or shoot sixty-three coyotes, but the Halandras flock still lost 250 to 300 lambs, "maybe more." Assuming that those figures are accurate, the loss from predation (figuring each lost lamb as a lost market potential of $70) ran Halandras from fifteen to twenty thousand dollars.

Environmentalists hotly dispute the standard figures that sheep producers give for their predator losses. And since most of the data available from official sources comes from possibly self-serving questionnaires solicited from sheep producers, it is hard to prove that the apparent rise in coyote-caused lamb deaths since the poison ban is a real one. Furthermore, the figures can be read in two ways.

Even if the percentage of predator kills has doubled since the 1950s, the rise could be explained simply as an arithmetical result of the decline in absolute numbers of sheep on open range pastures. If, for instance, the number of kills remained constant over time, the percentage loss would rise inevitably as the sheep population fell for a host of unrelated reasons, ranging from producers going into other lines of work to adverse market pressures. Obviously, coyotes do kill lambs, but the coyote controversy will never be resolved until a very thorough and disinterested study is made of coyote populations and the cause of lamb deaths on the range. Meanwhile, sheepmen seem to be fighting a losing battle against both *Canis latrans* and environmentally minded lawmakers.

The political weakness of sheep producers is, however, easily explained by their small numbers, distance from Washington, and lack of economic significance. And underneath all of these factors lies the fundamental stigma that sheep and sheepmen bear, both out West and in all America's folklore. As Halandras puts it, "No American child ever plays shepherds and Indians."

Gus Halandras hopes his own children will get out of the sheep business. "I want them to get an education," he says, "and train for a profession." Regas Halandras, fifteen, plans to become a lawyer. He and his younger brother are both accomplished herders, but if they sell their father's sheep and go to work in offices, their children will never know about the splendidly familial, outdoor, gypsy way of life on the range.

Perhaps open range grazing is an anachronism and a threat to the pristine quality of the western mountains. But it is still a vigorous tradition, locally symbolized by the initials that generations of herders have carved on aspens at campgrounds along the Bar H-L Road and nationally represented by meltingly tender domestic lamb raised on grass and thin air.

Unfortunately, through some Gresham's law of meat marketing, beef seems to have driven lamb virtually out of circulation. Lamb production rose slightly this year, but the basic picture is still dim. Regas Halandras knows that. His family may eat ground lamb, but MacDonald's doesn't serve it. And he must have learned another lesson about the low status of sheepherding when he went up to the edge of the family grazing allotments, at glorious Meadow Lake, and found the access road blocked with a log and posted with a sign forbidding automobile traffic. The ranger who put up the sign must have meant to keep tourist vehicles out. He apparently forgot that the sheep camps were coming.

### Lamb Liver in Salsa

Oil
1½ pounds lamb liver, cut in narrow strips
Flour
1 large onion, peeled and chopped
1 clove garlic, peeled and chopped
1½ cups tomato sauce
2 tablespoons chopped fresh parsley
1 teaspoon dried oregano
Salt
Pepper
1 lemon, sliced thinly (optional)

1. Heat oil in a skillet. Meanwhile, dredge liver strips in flour. Shake off excess flour and brown in hot oil. Remove strips with a spatula as soon as they brown and drain on paper toweling.
2. Add all remaining ingredients to the drippings in the skillet, along with 2 cups waters. Bring to a boil, reduce heat, and simmer 15 minutes.
3. Return liver strips to skillet and cook at a slow simmer. Test the liver after a few minutes and remove it to a serving platter as soon as it has absorbed the sauce's flavor. Do not overcook. Use excess sauce with spaghetti served on the side or at another meal.

Yield: 4–6 servings

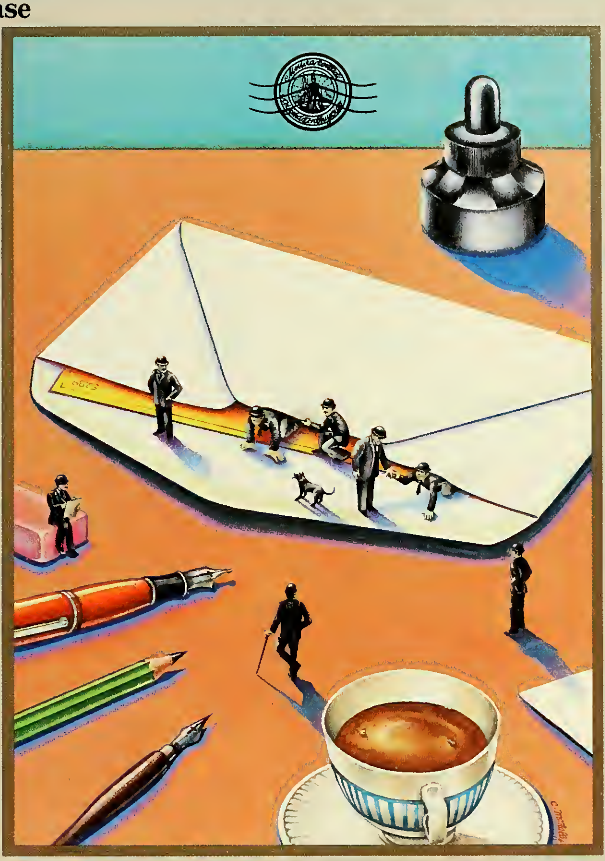
### Lamb Avgolemono

2 pounds lamb, stewing meat or shoulder, cut in chunks
2 tablespoons olive oil or butter
1 large onion, chopped
5–6 celery ribs cut in 2-inch sections
1 teaspoon salt
Pepper
3 large eggs
1 tablespoon cornstarch
Juice of 2 lemons

1. Brown meat, a few pieces at a time, in very hot oil, in a heavy pot. Reserve.
2. Reduce heat and brown onion and celery lightly in the same oil. Return browned lamb to pot, add salt, pepper, and 3 cups water. Bring to a boil, reduce heat and simmer, covered, for 1½ hours or until meat is tender.
3. To make sauce, remove 2 cups hot cooking liquid and reserve. Then, beat eggs in a bowl until frothy. Add cornstarch and beat until thoroughly incorporated. Add lemon juice gradually, beating as you add it. Pour in reserved cooking liquid in a slow stream, beating constantly.
4. Pour finished sauce over meat, which should still be hot. You can heat this gently, or keep it on the stove over low heat until ready to serve, but do not boil. The best thing is to serve it immediately.

Yield: 4–6 servings

# "Chief, there's more to this case than meets the eye!"



Tricky things, envelopes. They're so much a part of our lives we tend to forget what they come from.

Last year, some two million trees were harvested to produce the 112 billion envelopes you and we used to package our communications.

Which means our essential need for envelopes could conflict with our emotional attachment to trees.

Boise Cascade is a leading manufacturer of envelopes and manager of trees, so we're acutely aware of this conflict and our obligation to reconcile it.

That's why we plant five seedlings for every tree we harvest, why we explore new techniques that promise more trees per acre, more wood and paper per tree.

By managing our resources prudently we can provide the jobs, products and profits we all need while sustaining the forests we all love.

**Boise Cascade Corporation**
Wood and paper for today, trees for tomorrow.

# WE IMPROVED THE BEST MILEAGE CAR IN AMERICA.

Where do you go from up?

In the case of the 1981 Volkswagen Rabbit Diesel, we went under the hood.

We made the engine larger, and added enough extra horsepower to zip you from 0 to 50 in 11.4 brief seconds.

And that was just for starters.

On the outside, we gave the Rabbit Diesel a handsome new grille.

More visible directional signals in front.

And more visible taillights in back.

Inside, there's a whole new interior.

With a sleek new instrument panel; plusher, more comfortable seats; and an improved heating and air conditioning system that can get you up or down to 68° faster than ever.

Altogether, we made close to 1,000 changes, refinements and improve-

ments in the Rabbit Diesel for 1981.

But for all of those, the most impressive thing about it is the one thing we didn't change.

And that's its fuel economy.

The Rabbit Diesel still gets better mileage than every other car in the country.

In fact, the four-speed Rabbit Diesel gets even better mileage than it did last year.

For the four-speed, EPA estimated $\boxed{42}$ mpg, 56 mpg highway estimate. (Use "estimated mpg" for comparison to other cars. Mpg varies with speed, trip length and weather. Actual highway mpg will probably be less.)

If you're thinking about a diesel, you really should look at this one.

There isn't another diesel on the road that comes close to it.

But then, we started with a big advantage when we built the 1981 Rabbit Diesel.

We started with the 1980.

VOLKSWAGEN DOES IT AGAIN

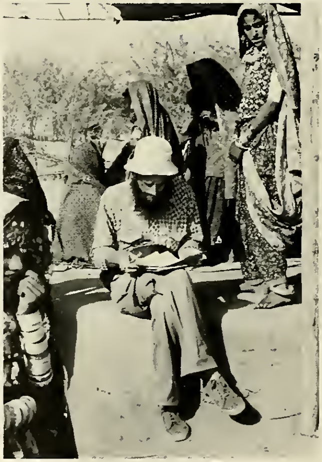
# Authors

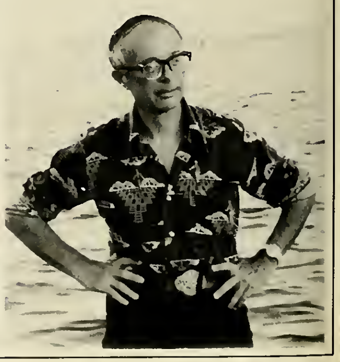
"The curiosity of our summer school students was the beginning of our interest in bogs. No feature of the Irish landscape prompted more questions," according to coauthors **Sharon Bohn Gmelch** and **George Gmelch**. The Gmelches, who both received their Ph.D.'s from the University of California at Santa Barbara in 1975, had previously done fieldwork with Irish tinkers. George Gmelch recently studied the return migration and readjustment of Irish emigrants, having carried out a similar study of indigenes in Newfoundland. The Gmelches have now turned their attention to Britain, where they are looking at the migration patterns and living needs of gypsies and tinkers. Sharon Bohn Gmelch is visiting assistant professor at Union College, Schenectady, New York, and adjunct assistant professor of anthropology at the State University of New York at Albany, where George Gmelch is assistant professor of anthropology.

**J. David Henry** became interested in the red fox the first time he saw one, in the Canadian boreal forest of northern Saskatchewan. He had gone there in 1971 to work on a black bear management program in Prince Albert National Park. Switching his attention to the foxes in the park, he found that, with much patience, he could observe them in their habitat. His observations developed into a doctoral research project on the adaptive strategies of the red fox. An environmental consultant and instructor of ecology at Saskatchewan Indian College of the University of Regina, Henry has also worked as a lumberjack. When city-bound, he watches cats hunt their prey in back alleys and vacant lots.



"I dreamed for years," explains architectural historian **Jean-Louis Bourgeois,** "of doing research as far removed as possible—in all senses—from the World Trade Center in New York." He was attracted to wind scoops and other desert structures after seeing their sculpturelike forms in pictures. With photographer Carollee Pelos, he documented rural Muslim shrines in Afghanistan, leaving the area not long before the Russian intervention. The two also explored architecture and local village life in the Great Indian Desert, and are currently off to the Sahara to gather more material for their planned book on desert architecture. Bourgeois is a graduate of Harvard University, where he studied literature and architectural history.

As a student at the University of Bologna in Italy, **Cesare Emiliani** found marine deposits dating back to the ice ages readily accessible, for Bologna long ago was a coastal city. Intrigued by the local material, Emiliani studied geology in Bologna and subsequently took an advanced degree in the subject at the University of Chicago. For almost a quarter of a century he has taught marine geology, with an emphasis on the history of the ice ages, at the University of Miami in Florida. His current research is centered on isotope paleoclimatology. Emiliani has written many papers on ancient temperatures and climates based on his work with deep-sea cores.



# THE NIKON FE
# A CAMERA TO STIR YOUR EMOTIONS

*The automatic Nikon FE is the creative camera par excellence—the embodiment of Nikon sophistication.*

*As Punjabi villagers say, "You never really know who a man is until you know who his grandfather and his ancestors were"*

**by Richard Kurin**

I was full of confidence when—equipped with a scholarly proposal, blessings from my advisers, and generous research grants—I set out to study village social structure in the Punjab province of Pakistan. But after looking for an appropriate fieldwork site for several weeks without success, I began to think that my research project would never get off the ground. Daily I would seek out villages aboard my puttering motor scooter, traversing the dusty dirt roads, footpaths, and irrigation ditches that crisscross the Punjab. But I couldn't seem to find a village amenable to study. The major problem was that the villagers I did approach were baffled by my presence. They could not understand why anyone would travel ten thousand miles from home to a foreign country in order to live in a poor village, interview illiterate peasants, and then write a book about it. Life, they were sure, was to be lived, not written about. Besides, they thought, what of any importance could they possibly tell me? Committed as I was to ethnographic research, I readily understood their viewpoint. I was a *babu log*—literally, a noble; figuratively, a clerk; and simply, a person of the city. I rode a motor scooter, wore tight-fitting clothing, and spoke Urdu, a language associated with the urban literary elite. Obviously, I did not belong, and the villagers simply did not see me fitting into their society.

The Punjab, a region about the size of Colorado, straddles the northern border of India and Pakistan. Partitioned between the two countries in 1947, the Punjab now consists of a western province, inhabited by Muslims, and an eastern one, populated in the main by Sikhs and Hindus. As its name implies—*punj* meaning "five" and *ab* meaning "rivers"—the region is endowed with plentiful resources to support widespread agriculture and a large rural population. The Punjab has traditionally supplied grains, produce, and dairy products to the peoples of neighboring and considerably more arid states, earning it a reputation as the breadbasket of southern Asia.

Given this predilection for agriculture, Punjabis like to emphasize that they are earthy people, having values they see as consonant with rural life. These values include an appreciation of, and trust in, nature; simplicity and directness of expression; an awareness of the basic drives and desires that motivate men (namely, *zan*, *zar*, *zamin*—"women, wealth, land"); a concern with honor and shame as abiding principles of social organization; and for Muslims, a deep faith in Allah and the teachings of his prophet Mohammad.

Besides being known for its fertile soils, life-giving rivers, and superlative agriculturists, the Punjab is also perceived as a zone of transitional culture, a region that has experienced repeated invasions of peoples from western and central Asia into the Indian subcontinent. Over the last four thousand years, numerous groups, among them Scythians, Parthians, Huns, Greeks, Moguls, Persians, Afghans, and Turks, have entered the subcontinent through the Punjab in search of bountiful land, riches, or power. Although Punjabis—notably Rajputs, Sikhs, and Jats—have a reputation for courage and fortitude on the battlefield, their primary, self-professed strength has been their ability to incorporate new, exogenous elements into their society with a minimum of conflict. Punjabis are proud that theirs is a multiethnic society in which diverse groups have been largely unified by a common language and by common customs and traditions.

Given this background, I had not expected much difficulty in locating a village in which to settle and conduct my research. As an anthropologist, I viewed myself as an "earthy" social scientist who, being concerned with basics, would have a good deal in common with rural Punjabis. True, I might be looked on as an invader of a sort; but I was benevolent, and sensing this, villagers were sure to incorporate me into their society with even greater ease than was the case for the would-be conquering armies that had preceded me. Indeed, they would welcome me with open arms.

I was wrong. The villagers whom I approached attributed my desire to live with them either to neurotic de-

¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign Service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll find yourself learning and speaking entirely in Spanish!

**This course turns your cassette player into a "teaching machine."** With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmatic Spanish Course comes in two volumes. You may order one or both courses:

☐ Volume I, Basic. (11 cassettes, 16 hours), instructor's manual and 464-page text, $115

☐ Volume II, Intermediate. (8 cassettes, 11½ hours), instructor's manual and 614 page text, $98 (New York residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's Spanish course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

If you're serious about heating with wood or coal:

Why settle for any stove that offers any less than these 10 important features?

1. Hand-set and bonded tiles are safer than blistering metal, radiate gentle heat far longer.
2. Top grille lifts for cooking.
3. Tempered glass fire-door window lets you view the flames without reducing combustion efficiency.
4. Lever-activated shaking grate separates coals from ashes, increasing burning efficiency.
5. Wrought-iron style front grille swings open at a touch.
6. Suspended burning basket lets you burn both wood and coal.
7. Easily removable ash pan pulls out for dumping.
8. Ash catcher moves out when ashpan door is opened. No more floor mess!
9. Liquid-expansion thermostat is more precise and reacts much faster than crude bimetallic devices.
10. Heats both by convection and radiant warmth — you're barely aware of a heat source.

Beneath its splendid good looks, the airtight WESO Ceramic Tile Stove is a true marvel of modern combustion technology. Producing a mild yet penetrating heat no metal stove can match, the WESO will warm you night and morning, and all through the day. Its lasting beauty will grace the most tastefully decorated home.

**Send $1 for literature portfolio showing all 5 tile colors PLUS news about two new coalburning stoves.**

Ceramic Radiant Heat

lusions or nefarious ulterior motives. Perhaps, so the arguments went, I was really after women, land, or wealth.

On the day I had decided would be my last in search of a village, I was driving along a road when I saw a farmer running through a rice field and waving me down. I stopped and he climbed on the scooter. Figuring I had nothing to lose, I began to explain why I wanted to live in a village. To my surprise and delight, he was very receptive, and after sharing a pomegranate milkshake at a roadside shop, he invited me to his home. His name was Allah Ditta, which means "God given," and I took this as a sign that I had indeed found my village.

"My" village turned out to be a settlement of about fifteen hundred people, mostly of the Nunari *qaum*, or "tribe." The Nunaris engage primarily in agriculture (wheat, rice, sugar cane, and cotton), and most families own small plots of land. Members of the Bhatti tribe constitute the largest minority in the village. Although traditionally a warrior tribe, the Bhattis serve in the main as the village artisans and craftsmen.

On my first day in the village I tried explaining in great detail the purposes of my study to the village elders and clan leaders. Despite my efforts, most of the elders were perplexed about why I wanted to live in their village. As a guest, I was entitled to the hospitality traditionally bestowed by Muslim peoples of Asia, and during the first evening I was assigned a place to stay. But I was an enigma, for guests leave, and I wanted to remain. I was also perceived as being strange, for I was both a non-Muslim and a non-Punjabi, a type of person not heretofore encountered by most of the villagers. Although I tried to temper my behavior, there was little I could say or do to dissuade my hosts from the view that I embodied the antithesis of Punjabi values. While I was able to converse in their language, Jatki, a dialect of western Punjabi, I was only able to do so with the ability of a four-year-old. This achievement fell far short of speaking the *t'et'*, or "genuine form," of the villagers. Their idiom is rich with the terminology of agricultural operations and rural life. It is unpretentious, uninflected, and direct, and villagers hold high opinions of those who are good with words, who can speak to a point and be convincing. Needless to say, my infantile babble realized

Rolex owners have grown accustomed to prices that begin at $500. And if you're considering a Rolex with any gold in it, you can figure to spend $2000 or more.

To justify touching the stratosphere, Rolex delivers an irresistable mixture of legend and quality. With solidness approaching the Rock of Gibraltar, certified Swiss chronometer accuracy, and a reputation for durability, this prestigious name has continued to maintain a position of high esteem.

And as if quality alone weren't enough, it also bestows upon its possessor that sure distinction usually reserved only for Rolls Royce automobiles—visual confirmation that its owner has arrived.

23
Realtime
QUARTZ

A water-tight screw-down setting stem—usually found only on the most costly watches—is just one reason why Realtime guarantees underwater protection down to 165 feet. And why you'd expect this prestigious looking timekeeper to cost a lot more than it does.

**Why everybody's switching to quartz. Even Rolex™.**

Quartz crystals are far and away the most accurate timekeeping element the world has ever known.

That's why the finest movements depend on quartz vibrations (32,768 per second). And why even Rolex, an acknowledged pioneer in mechanical "mainspring" watches, is now turning to the more reliable quartz precision.

How reliable? The watch pictured below guarantees ±5 second-a-month accuracy—exceeding the highly regarded Swiss Chronometer standards. Its Swiss made movement utilizes the most advanced solid state technologies. And the most proven quality assurance known to man: Swiss pride.

Because of its up-to-the-minute electronic circuitry, this same timepiece should never need cleaning, oiling or repair work. Just a battery change every 18 months or so (and any jeweler can do the job).

But in case you haven't noticed, this extraordinary timekeeper isn't a Rolex. It's a Realtime.

**Not just a copy. A commitment.**

While its design is an unmistakable tribute to the prestigious Rolex look, this Realtime introduces some pleasing innovations (the case, for example, is thinner and more compact than the Rolex).

But for the most part, Realtime's skilled casemakers were committed to faithfully reproducing the original design—detail for detail. From the stylized gold bezel to the supple link bracelet to the magnifying date window on the crystal.

These same demanding standards are reflected in Realtime's superb construction. To prevent tarnishing or scratches, both case and bracelet are machined from solid stainless steel (please don't confuse this with less expensive "silvertone" finishes). The classic analog hands and dial are coated with tritium for easy visibility, even at night. And the setting stem, similar to the Rolex, features a screw-down locking mechanism—the same water-tight design found in submarine hatches.

Add to that a tightly sealed case and crystal, and it's no wonder Realtime guarantees water protection to 5 atmospheres (165 feet below the surface). The same underwater depth as many Rolex models.

**How Realtime saved you $1850.**

In days when only a master watchmaker's skilled fingers could create a high caliber timepiece, a lofty price tag was understandable.

But today's computer-engineered electronic movements have made perfection possible at a much lower price. Selecting the finest of these movements (made in Switzerland), Realtime dramatically reduces labor costs by assembling the watch in Taiwan—where handwork, still considered an art, is also (by European standards) a bargain.

And instead of inflating the price by using solid gold, they have selectively plated the links, bezel and hands. By the way, those rich 5 microns of real gold are enough to preserve the lustrous look, even after years of rugged wear.

So how much did Realtime's cost-cutting measures save you?

Remarkably, the watch you're looking at sells for only $149.

And it can be yours with the ease of a free phone call. But to avoid disappointment, please order early; our supply is really quite limited (initial production run is only 500 units). You must be solidly convinced that your new Realtime is an excellent investment. If not, return it within 2 weeks of receipt for a prompt, courteous refund. Watch comes complete with battery in place, one year warranty, convenient service by mail, gift box and full instructions.

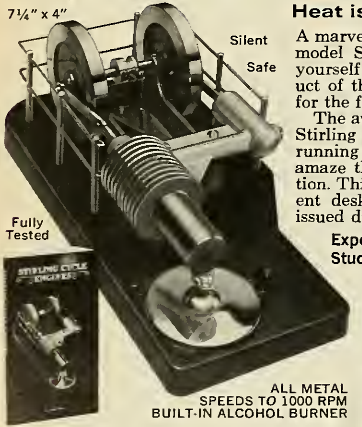
*The Amazing Stirling Cycle* **Hot Air Engine**

**Heat is the only fuel required!**



A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

**Experimenters • Hobbyists' Power Source**
**Students • Collectors • Model Engineers**

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

none of these characteristics and evoked no such respect.

Similarly, even though I wore indigenous dress, I was inept at tying my *lungi*, or pant cloth. The fact that my *lungi* occasionally fell off and revealed what was underneath gave my neighbors reason to believe that I indeed had no shame and could not control the passions of my *nafs*, or "libidinous nature."

This image of a doltish, shameless infidel barely capable of caring for himself lasted for the first week of my residence in the village. My inability to distinguish among the five varieties of rice and four varieties of lentil grown in the village illustrated that I knew or cared little about nature and agricultural enterprise. This display of ignorance only served to confirm the general consensus that the mysterious morsels I ate from tin cans labeled "Chef Boy-ar-Dee" were not really food at all. Additionally, I did not oil and henna my hair, shave my armpits, or perform ablutions, thereby convincing some commentators that I was a member of a species of subhuman beings, possessing little in the form of either common or moral sense. That the villagers did not quite grant me the status of a person was reflected by their not according me a proper name. In the Punjab, a person's name is equated with honor and respect and is symbolized by his turban. A man who does not have a name, or whose name is not recognized by his neighbors, is unworthy of respect. For such a man, his turban is said to be either nonexistent or to lie in the dust at the feet of others. To be given a name is to have one's head crowned by a turban, an acknowledgment that one leads a responsible and respectable life. Although I repeatedly introduced myself as "Rashid Karim," a fairly decent Pakistani rendering of Richard Kurin, just about all the villagers insisted on calling me *Angrez* ("Englishman"), thus denying me full personhood and implicitly refusing to grant me the right to wear a turban.

As I began to pick up the vernacular, to question villagers about their clan and kinship structure and trace out relationships between different families, my image began to change. My drawings of kinship diagrams and preliminary census mappings were looked upon not only with wonder but also suspicion. My neighbors now began to think there might be a method to my madness. And so there was.

Now I had become a spy. Of course it took a week for people to figure out whom I was supposedly spying for. Located as they were at a crossroads of Asia, at a nexus of conflicting geopolitical interests, they had many possibilities to consider. There was a good deal of disagreement on the issue, with the vast majority maintaining that I was either an American, Russian, or Indian spy. A small, but nonetheless vocal, minority held steadfastly to the belief that I was a Chinese spy. I thought it all rather humorous until one day a group confronted me in the main square in front of the nine-by-nine-foot mud hut that I had rented. The leader spoke up and accused me of spying. The remainder of the group grumbled *jahsus! jahsus!* ("spy! spy!"), and I realized that this ad hoc committee of inquiry had the potential of becoming a mob.

To be sure, the villagers had good reason to be suspicious. For one, the times were tense in Pakistan—a national political crisis gripped the country and the populace had been anxious for months over the uncertainty of elections and effective governmental functions. Second, keenly aware of their history, some of the villagers did not have to go too far to imagine that I was at the vanguard of some invading group that had designs upon their land. Such intrigues, with far greater sophistication, had been played out before by nations seeking to expand their power into the Punjab. That I possessed a gold seal letter (which no one save myself could read) from the University of Chicago to the effect that I was pursuing legitimate studies was not enough to convince the crowd that I was indeed an innocent scholar.

I repeatedly denied the charge, but to no avail. The shouts of *jahsus! jahsus!* prevailed. Confronted with this I had no choice.

"Okay," I said. "I admit it. I am a spy!"

The crowd quieted for my long-awaited confession.

"I am a spy and am here to study this village, so that when my country attacks you we will be prepared. You see, we will not bomb Lahore or Karachi or Islamabad. Why should we waste our bombs on millions of people, on factories, dams, airports, and harbors? No, it is far more advantageous to bomb this strategic small village replete with its mud huts, livestock, Persian wheels, and one light bulb. And when we bomb this village, it

## RARE WHALE COMMEMORATIVE

SEA RESOURCE MANAGEMENT
2 PA'ANGA

*Actual Size*

This beautiful pure-silver proof (mirror-finish) coin has been authorized by the South Pacific island nation of Tonga (Friendly Islands). This striking coin depicts the rare humpback whale majestically rising from the sea, with the King of Tonga pictured on the other side.

Officially struck by the Australian Canberra Mint under United Nations auspices, the total mintage is limited to only 2,000 which will insure excellent investment potential.

This rare and attractive collector’s item is modestly priced at $185.00. Send your check without delay, limit 2 per order please.

CONSERVATION COINS
P.O. Box 175 Garden City, N.Y. 11530

is imperative that we know how Allah Ditta is related to Abdullah, and who owns the land near the well, and what your marriage customs are.”

Silence hung over the crowd, and then one by one the assemblage began to disperse. My sarcasm had worked. The spy charges were defused. But I was no hero in light of my performance, and so I was once again relegated to the status of a nonperson without an identity in the village.

I remained in limbo for the next week, and although I continued my attempts to collect information about village life, I had my doubts as to whether I would ever be accepted by the villagers. And then, through no effort of my own, there was a breakthrough, this time due to another Allah Ditta, a relative of the village headman and one of my leading accusers during my spying days.

I was sitting on my woven string bed on my porch when Allah Ditta approached, leading his son by the neck. “Oh, *Angrez*!” he yelled, “this worthless son of mine is doing poorly in school. He is supposed to be learning English, but he is failing. He has a good mind, but he’s lazy. And his teacher is no help, being more intent upon drinking tea and singing film songs than upon teaching English. Oh son of an Englishman, do you know English?”

“Yes, I know English,” I replied, “after all, I am an *Angrez*.”

“Teach him,” Allah Ditta blurted out, without any sense of making a tactful request.

And so, I spent the next hour with the boy, reviewing his lessons and correcting his pronunciation and grammar. As I did so, villagers stopped to watch and listen, and by the end of the hour, nearly one hundred people had gathered around, engrossed by this tutoring session. They were stupefied. I was an effective teacher, and I actually seemed to know English. The boy responded well, and the crowd reached a new consensus. I had a brain. And in recognition of this achievement I was given a name—“Ustad Rashid,” or Richard the Teacher.

Achieving the status of a teacher was only the beginning of my success. The next morning I awoke to find the village sugar vendor at my door. He had a headache and wanted to know if I could cure him.

“Why do you think I can help you?” I asked.

Discovery Tours

GALAPAGOS ISLANDS CRUISE
June 13 to 25, 1981

Share the educational holiday of a lifetime with American Museum scholars and 65 compatible travelers aboard the comfortable M.V. Buccaneer. Enjoy superb climate and sandy beaches, while exploring volcanic landscapes, home to exotic and tame birds and reptiles. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

Bhai Khan answered, "Because you are a *ustad*, you have a great deal of knowledge."

The logic was certainly compelling. If I could teach English, I should be able to cure a headache. I gave him two aspirins.

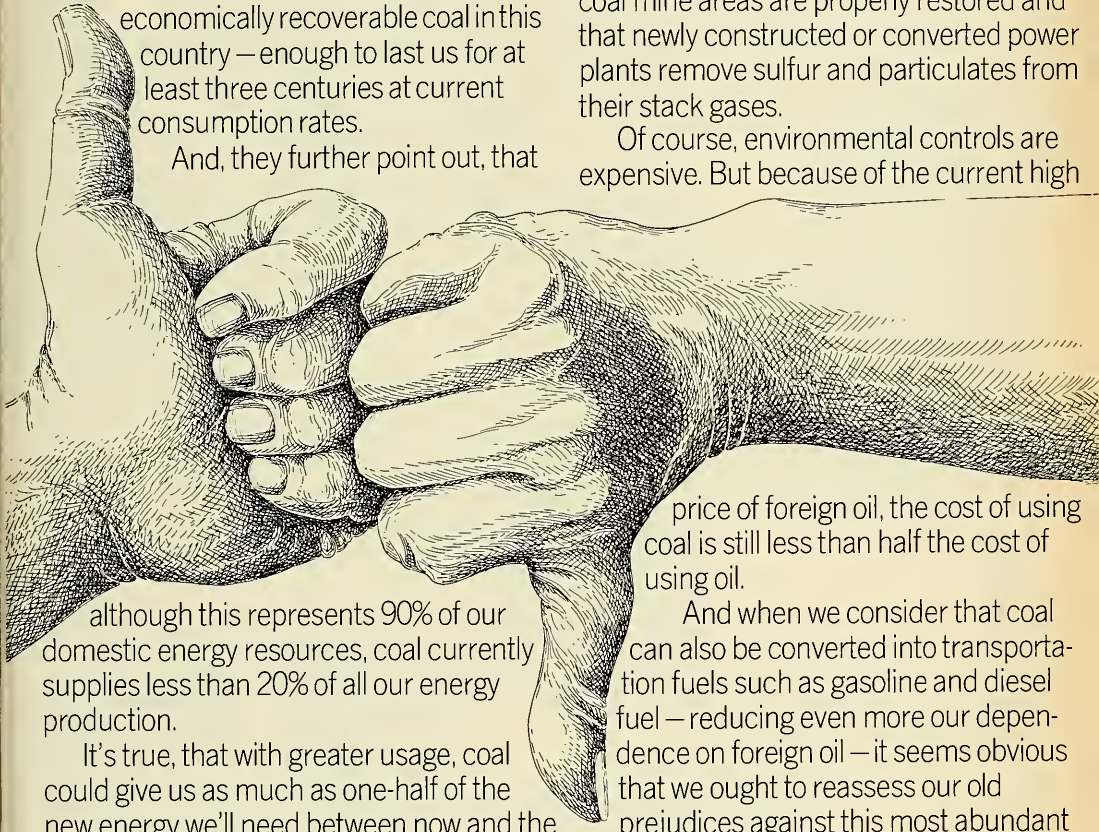
An hour later, my fame had spread. Bhai Khan had been cured, and he did not hesitate to let others know that it was the *ustad* who had been responsible. By the next day, and in fact for the remainder of my stay, I was to see an average of twenty-five to thirty patients a day. I was asked to cure everything from coughs and colds to typhoid, elephantiasis, and impotency. Upon establishing a flourishing and free medical practice, I received another title, *hakim*, or "physician." I was not yet an anthropologist, but I was on my way.

A few days later I took on yet another role. One of my research interests involved tracing out patterns of land ownership and inheritance. While working on the problem of figuring out who owned what, I was approached by the village watchman. He claimed he had been swindled in a land deal and requested my help. As the accused was not another villager, I agreed to present the watchman's case to the local authorities.

Somehow, my efforts managed to achieve results. The plaintiff's grievance was redressed, and I was given yet another title in the village—*wakil*, or "lawyer." And in the weeks that followed, I was steadily called upon to read, translate, and advise upon various court orders that affected the lives of the villagers.

My roles as teacher, doctor, and lawyer not only provided me with an identity but also facilitated my integration into the economic structure of the community. As my imputed skills offered my neighbors services not readily available in the village, I was drawn into exchange relationships known as *seipi*. *Seipi* refers to the barter system of goods and services among village farmers, craftsmen, artisans, and other specialists. Every morning Roshan the milkman would deliver fresh milk to my hut. Every other day Hajam Ali the barber would stop by and give me a shave. My next-door neighbor, Nura the cobbler, would repair my sandals when required. Ghulam the horse-cart driver would transport me to town when my motor scooter was in disrepair. The parents of my students would send

# Some insist coal is good. Some insist coal is bad.
# We insist it's not that black or white.



Those who insist that coal is good point out that we have over 200 billion tons of economically recoverable coal in this country—enough to last us for at least three centuries at current consumption rates.

And, they further point out, that although this represents 90% of our domestic energy resources, coal currently supplies less than 20% of all our energy production.

It's true, that with greater usage, coal could give us as much as one-half of the new energy we'll need between now and the year 2000—enough to help loosen the dangerous ties that bind us to expensive and insecure foreign oil.

But those who insist that coal is bad point to abandoned mines which scar the landscape and allow acid water to seep into streams.

And to the fact that coal contains ash and sulfur which, if not removed, can pollute the air when burned.

Still, we believe that these days the advantages of coal outweigh its disadvantages.

Because these days we have extremely tough environmental laws.

Laws that require the restoration of mined lands and the protection of air and water resources. Laws that ensure that coal mine areas are properly restored and that newly constructed or converted power plants remove sulfur and particulates from their stack gases.

Of course, environmental controls are expensive. But because of the current high price of foreign oil, the cost of using coal is still less than half the cost of using oil.

And when we consider that coal can also be converted into transportation fuels such as gasoline and diesel fuel—reducing even more our dependence on foreign oil—it seems obvious that we ought to reassess our old prejudices against this most abundant of all fossil fuels.

At least Atlantic Richfield thinks so.

**There are no easy answers.**

# New from Time-Life Records!

## American Musicals

# Enjoy 50 glorious years of Broadway triumphs.

## Just released: an unprecedented recording achievement!

Now, TIME-LIFE RECORDS presents the most comprehensive collection of music for the stage ever assembled: AMERICAN MUSICALS—a magnificent series of record albums that captures the excitement of five decades of Broadway's most acclaimed masterpieces!

### Our greatest composers...our most enduring stars—presented on recordings of the finest quality.

Unforgettable performances by such stars as Mary Martin, Ethel Merman, Ezio Pinza, Rex Harrison, Julie Andrews, Alfred Drake and Richard Burton—to name just a few—create an unparalleled tribute to the American musical stage.

Each album in AMERICAN MUSICALS features three major shows by one or more outstanding composer/lyricist teams. And each recording will be presented in its *original* form: if the best performance was recorded in monaural sound, our recording will flawlessly reproduce that sound—with no electronic gimmickry. When a show was recorded in stereo, we'll reproduce it in the fullest, broadest range that advanced technology makes possible.

### Begin your collection with the music of *Rodgers and Hammerstein.* Yours to audition for 10 days with no obligation.

Your introductory album, *Rodgers and Hammerstein,* features more than 40 selections from three of the most memorable musicals in the history of the American musical—all *original cast recordings:* Oklahoma! (you'll hear the original stars—Alfred Drake, Joan Roberts and Celeste Holm)...South Pacific, with its bravura performances by Ezio Pinza and Mary Martin...and Carousel, starring the great John Raitt and Jan Clayton.

*Rodgers and Hammerstein*—and each 3-record album in the AMERICAN MUSICALS series—comes with a beautifully illustrated 48-page booklet. Audition the introductory album for 10 days without cost or obligation just by mailing the attached postpaid reply card.

Future albums planned for inclusion in the AMERICAN MUSICALS series will feature the immortal works of: • *Cole Porter:* unforgettable scores from Anything Goes, Kiss Me, Kate and Can-Can. • *Lerner and Loewe:* featuring Brigadoon, My Fair Lady and Camelot. • *Jerome Kern:* you'll hear Show Boat, Roberta and Very Good Eddie. • *Rodgers and Hart:* enjoy Babes in Arms, Pal Joey and The Boys from Syracuse....and many more!

### FREE bonus— *Broadway's Greatest Musicals*

If you're a Broadway buff, you'll want this illustrated book packed with 519 pages of information about every aspect of the musical theater. *Broadway's Greatest Musicals*—a $14.95 value—is included at no extra cost as part of your subscription!

Hear for yourself what a rewarding listening experience awaits you in AMERICAN MUSICALS. Send for a 10-day free audition of your introductory album—mail the card today.

**If card is missing, mail coupon to TIME-LIFE RECORDS, Time & Life Bldg., Chicago, IL 60611.**

### Oh, those wonderful songs! Your first album presents:

**Oklahoma!** People Will Say We're In Love • The Surrey With The Fringe On Top • Oh, What a Beautiful Mornin' • Pore Jud Is Daid • I Cain't Say No • All er Nothin' • Oklahoma • and more!

**Carousel** You'll Never Walk Alone • June is Bustin' Out All Over • If I Loved You • This Was a Real Nice Clambake • Soliloquy • Mr. Snow • and more!

**South Pacific** Some Enchanted Evening • Younger Than Springtime • Bali Ha'i • I'm Gonna Wash That Man Right Outa My Hair • There Is Nothin' Like a Dame • This Nearly Was Mine • and more!

**Julie Andrews and Rex Harrison:** In My Fair Lady, they captivated audiences with "I Could Have Danced All Night" and "I've Grown Accustomed To Her Face."

**Ethel Merman:** With a dynamism few performers can match, she sang "Doin' What Comes Natur'lly" in Annie Get Your Gun.

---

**TIME-LIFE RECORDS** Time & Life Building, Chicago, IL 60611 RQACQ1

YES! I would like to audition *Rodgers & Hammerstein,* my introduction to AMERICAN MUSICALS. Please send this three-record album to me for 10 days' free audition, along with a copy of *Broadway's Greatest Musicals,* and enter my subscription to AMERICAN MUSICALS. If I decide to keep *Rodgers & Hammerstein,* I will pay $24.95 plus shipping and handling. I will then receive future albums (each one containing three 12-inch LP records) from AMERICAN MUSICALS, shipped one album at a time approximately every other month. Each album will be $24.95 plus shipping and handling and will come on the same 10-day free-audition basis. There is no minimum number of albums that I must buy and I may cancel my subscription at any time simply by notifying you. If I do not choose to keep *Rodgers & Hammerstein,* I will return it and *Broadway's Greatest Musicals* within 10 days, my subscription for future albums will be canceled and I will be under no further obligation.

☐ **Please check here if you prefer three Dolby-encoded tape cassettes ($3 extra).** ROACK2

me sweets and sometimes delicious meals. In return, none of my neighbors asked for direct payment for the specific actions performed. Rather, as they told me, they would call upon me when they had need of my services. And they did. Nura needed cough syrup for his children, the milkman's brother needed a job contact in the city, students wanted to continue their lessons, and so on. Through *seipi* relations, various neighbors gave goods and services to me, and I to them.

Even so, I knew that by Punjabi standards I could never be truly accepted into village life because I was not a member of either the Nunari or Bhatti tribe. As the villagers would say, "You never really know who a man is until you know who his grandfather and his ancestors were." And to know a person's grandfather or ancestors properly, you had to be a member of the same or a closely allied tribe.

The Nunari tribe is composed of a number of groups. The nucleus consists of four clans—Naul, Vadel, Saddan, and More—each named for one of four brothers thought to have originally founded the tribe. Clan members are said to be related by blood ties, also called *pag da sak*, or "ties of the turban." In sharing the turban, members of each clan share the same blood, the same honor, and the same name. Other clans, unrelated by ties of blood to these four, have become attached to this nucleus through a history of marital relations or of continuous political and economic interdependence. Marital relations, called *gag da sak*, or "ties of the skirt," are conceived of as relations in which alienable turbans (skirts) in the form of women are exchanged with other, non-turban-sharing groups. Similarly, ties of political and economic domination and subordination are thought of as relations in which the turban of the client is given to that of the patron. A major part of my research work was concerned with reconstructing how the four brothers formed the Nunari tribe, how additional clans became associated with it, and how clan and tribal identity were defined by nomenclature, codes of honor, and the symbols of sharing and exchanging turbans.

To approach these issues I set out to reconstruct the genealogical relationships within the tribe and between the various clans. I elicited genealogies from many of the villagers and

# GOOSE DOWN... A COMFORTABLE WAY TO BEAT THE HIGH COST OF ENERGY...

## *AT A PRICE YOU CAN AFFORD*

The way fuel costs are rising, you could go broke if you turn up your thermostat on those cold winter nights. That's no exaggeration. Turn your thermostat down (as low as 55°F) and save fuel when you wrap yourself in a warm and cozy goose down product from Mountainside Concepts: Color-Coordinated goose down filled comforters, robes and slippers.

Goose Down-
NATURES FINEST
INSULATOR.

**GOOSE DOWN COMFORTERS:** Our comforters are light in weight without the oppresive heaviness of layers of blankets. Safe too. They are made to our meticulous construction standards with a tightly woven 100% cotton cambric cover, and hidden innerstitching to prevent down leakage. (Sewn-through stitching is never used.) This assures you many years of continuous use. Machine washable. COLORS: light blue or camel.
SIZES: Twin 66"x 85" **$90.00**
Full/Queen 86"x 85" **$125.00**
King 98"x 85" **$150.00** (add $2.50 shipping per piece)

**GOOSE DOWN ROBES:** For the fashion conscious woman. Try our contoured goose down robes on those chilly evenings. The fabric is a down-proof poly/cotton/nylon. You can snuggle up with a good book in warmth and comfort in our generously filled goose down robe. Machine washable. COLORS: Royal Blue, Burgundy and Chocolate
SIZES: small (8-10), medium (12-14), large (16-18)
PRICE: **$75.00** (all sizes) plus $2.50 shipping per unit.

**COMPARE OUR PRICES:** We've shopped the market and know our prices are the best to be found anywhere in America. Better than the traditional retail stores' "sale" prices. Do not compare our products with those containing the less expensive down/feather blends. But do compare us with quality merchandise. We're sure you will find Mountainside Concepts prices and quality the best buy.

**GOOSE DOWN SLIPPERS:** When your feet get chilly, slip on a pair of our generously filled goose down slippers. The fabric is a down-proof poly/cotton/nylon. A perfect complement to our goose down robes. Machine washable. COLORS: Royal Blue, Burgundy and Chocolate
SIZES: small (5-6½), medium (7-8½), large (9-10½)
PRICE: **$9.95** (all sizes) plus $1.00 shipping per unit.

**GUARANTEE:** We're so sure you'll cherish the goose down products from Mountainside Concepts we make you this unconditional guarantee: after 15 days, if for any reason you aren't fully satisfied with any of our products, return them for a full refund (including postage). Additionally, we will replace any product we sell if any defects in workmanship or materials appear within five years. We challenge anyone to equal this guarantee.

questioned older informants about the history of the Nunari tribe. Most knew only bits and pieces of this history, and after several months of interviews and research, I was directed to the tribal genealogists. These people, usually not Nunaris themselves, perform the service of memorizing and then orally relating the history of the tribe and the relationships among its members. The genealogist in the village was an aged and arthritic man named Hedayat, who in his later years was engaged in teaching the Nunari genealogy to his son, who would then carry out the traditional and hereditary duties of his position.

The villagers claimed that Hedayat knew every generation of the Nunari from the present to the founding brothers and even beyond. So I invited Hedayat to my hut and explained my purpose.

"Do you know Allah Ditta son of Rohm?" I asked.

"Yes, of course," he replied.

"Who was Rohm's father?" I continued.

"Shahadat Mohammad," he answered.

"And his father?"

"Hamid."

"And his?"

"Chigatah," he snapped without hesitation.

I was now quite excited, for no one else in the village had been able to recall an ancestor of this generation. My estimate was that Chigatah had been born sometime between 1850 and 1870. But Hedayat went on.

"Chigatah's father was Kamal. And Kamal's father was Nanak. And Nanak's father was Sikhu. And before him was Dargai, and before him Maiy. And before him was Siddiq. And Siddiq's father was Nur. And Nur's Asmat. And Asmat was of Channa. And Channa of Nau. And Nau of Bhatta. And Bhatta was the son of Koduk."

Hedayat had now recounted sixteen generations of lineal ascendants related through the turban. Koduk was probably born in the sixteenth century. But still Hedayat continued.

"Sigun was the father of Koduk. And Man the father of Sigun. And before Man was his father Maneswar. And Maneswar's father was the founder of the clan, Naul."

This then was a line of the Naul clan of the Nunari tribe, ascending twenty-one generations from the present descendants (Allah Ditta's sons) to the founder, one of four brothers who lived perhaps in the fifteenth century. I asked Hedayat to recite genealogies of the other Nunari clans, and he did, with some blanks here and there, ending with Vadel, More, and Saddan, the other three brothers who formed the tribal nucleus. I then asked the obvious question, "Hedayat, who was the father of these four brothers? Who is the founding ancestor of the Nunari tribe?"

"The father of these brothers was not a Muslim. He was an Indian rajput [chief]. The tribe actually begins with the conversion of the four brothers," Hedayat explained.

"Well then," I replied, "who was this Indian chief?"

He was a famous and noble chief who fought against the Moguls. His name was Raja Kurin, who lived in a massive fort in Kurinnagar, about twenty-seven miles from Delhi."

"What!" I asked, both startled and unsure of what I had heard.

"Raja Kurin is the father of the brothers who make up—"

"But his name! It's the same as mine," I stammered. "Hedayat, my name is Richard Kurin. What a coincidence! Here I am living with your tribe thousands of miles from my home and it turns out that I have the same name as the founder of the tribe! Do you think I might be related to Raja Kurin and the Nunaris?"

Hedayat looked at me, but only for an instant. Redoing his turban, he tilted his head skyward, smiled, and asked, "What is the name of your father?"

I had come a long way. I now had a name that could be recognized and respected, and as I answered Hedayat, I knew that I had finally and irrevocably fit into "my" village. Whether by fortuitous circumstance or by careful manipulation, my neighbors had found a way to take an invading city person intent on studying their life and transform him into one of their own, a full person entitled to wear a turban for participating in, and being identified with, that life. As has gone on for centuries in the region, once again the new and exogenous had been recast into something Punjabi.

**Epilogue:** There is no positive evidence linking the Nunaris to a historical Raja Kurin, although there are several famous personages identified by that name (also transcribed as Karan and Kurran). Estimated from the genealogy recited by Hedayat, the founding of the tribe by the four brothers appears to have occurred sometime between 440 and 640 years ago, depending on the interval assumed for each generation. On that basis, the most likely candidate for Nunari progenitor (actual or imputed) is Raja Karan, ruler of Anhilvara (Gujerat), who was defeated by the Khilji Ala-ud-Din in 1297 and again in 1307. Although this is slightly earlier than suggested by the genealogical data, such genealogies are often telescoped or otherwise unreliable.

Nevertheless, several aspects of Hedayat's account make this association doubtful. First, Hedayat clearly identifies Raja Kurin's conquerors as Moguls, whereas the Gujerati Raja Karan was defeated by the Khiljis. Second, Hedayat places the Nunari ancestor's kingdom only twenty-seven miles from Delhi. The Gujerati Raja Karan ruled several kingdoms, none closer than several hundred miles to Delhi.

Other circumstances, however, offer support for this identification of the Nunari ancestor. According to Hedayat, Raja Kurin's father was named Kam Deo. Although the historical figure was the son of Serung Deo, the use of "Deo," a popular title for the rajas of the Vaghela and Solonki dynasties, does seem to place the Nunari founder in the context of medieval Gujerat. Furthermore, Hedayat clearly identifies the saint (*pir*) said to have initiated the conversion of the Nunaris to Islam. This saint, Mukhdum-i-Jehaniyan, was a contemporary of the historical Raja Karan.

Also of interest, but as yet unexplained, is that several other groups living in Nunari settlement areas specifically claim to be descended from Raja Karan of Gujerat, who is said to have migrated northward into the Punjab after his defeat. Controverting this theory, the available evidence indicates that Raja Karan fled, not toward the Punjab, but rather southward to the Deccan, and that his patriline ended with him. It is his daughter Deval Devi who is remembered: she is the celebrated heroine of "Ashiqa," a famous Urdu poem written by Amir Khusrau in 1316. She was married to Khizr Khan, the son of Karan's conqueror; nothing is known of her progeny.

*Richard Kurin teaches community development at Southern Illinois University at Carbondale.*

Canon
A-1
CANON LENS MADE IN JAPAN
CANON LENS FD 50mm 1:1.8

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

Programmed: 350 8.5
Canon
Canon

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.

*NOW! For the first time . . .* **a clear, concise, understandable book on the Earth's most promising energy source.**

**Solar Electricity** **Only $6.95 Ppd.**

140 EASY-TO-READ FACT FILLED PAGES
**Loaded with charts, graphs, pictures of actual solar installations—by World's Foremost Authority SOLAREX**

**Most books and articles on Solar Energy are either jam packed with mind-boggling technical jargon, or they're so basic you can't find what you really want to know.**

Here for the first time—is a definitive study of all the real (not blue sky) applications of solar, written by the world's leading experts but written in everyday language so you can understand and put to work the real, significant benefits of Solar electricity in scores of practical ways, both large and small. Must reading for everyone from the casual enthusiast right up to the trained solar professional.

Nine Clear, Concise Chapters
Covers everything from a glossary of solar electric terms, how to use cells and practical solar electric generators, to the rapidly exploding variety of industrial, educational, consumer, and military applications. It also includes solar electric projects, commercially available accessories the use of solar cells as light sensors rather than as power sources, and much, much more.

**Don't take our word for it!**
Take your time. In fact—take two full weeks. Order the book. Read it. See if you don't completely agree that this is the best Solar electric summary you've ever read. If not—simply return the book and we'll refund your money by return mail or credit your account.

# Oh Sex, Where Is Thy Sting?

*Insect romance can be a deadly serious affair*

**by Milton Love**

You might expect male insects or spiders to view life as just one salacious experience after another. After all, many are sort of simpletons, ready to mate anytime, anywhere, seemingly with anything. (Your mother was right, you know, they are After Only One Thing.) If, in his exuberance, a male mates at the wrong time—for example, with a female carrying immature eggs—he usually loses little. Sperm is cheap to produce, and its loss will not significantly hinder future reproductive possibilities.

However, pitfalls and traumas line the primrose path of lust for our intrepid Lotharios.

A female must be careful about when and with whom she copulates. For instance, if her eggs are already fertilized, further mating serves no purpose, and her time is better spent in feeding, avoiding predators, and so forth. Moreover, since they expend a great deal of energy in producing eggs and perhaps caring for young, females must exercise some discretion in choosing mates.

Thus, an overeager male faced with a more reticent, pragmatic female may find sex to be a tension-filled, and possibly terminal, experience.

Female rejection of male advances is rarely subtle. After her eggs are fertilized, the female ground beetle, *Pterostichus lucublandus*, will not mate again. An unreceptive female runs away when a male attempts to mate with her. If the male continues his advances, the female discharges a liquid from the tip of her abdomen. The male immediately stops and tries to wipe the substance off his feet and antennae, but within ten seconds, like a Keystone Cop falling off a motorcycle, the beetle keels over in a coma. He remains comatose for one to three hours, thereby allowing the female enough time to leave the area and safely deposit her eggs (which the male might otherwise eat).

If a female does not choose to mate, she may so indicate by attacking and sometimes killing the male, a behavior particularly common in spiders. Hence, male spiders are usually quite tentative in early courtship behavior. Many will first pluck at the webs of females to see how they respond. A fast-charging female is not a positive sign. In purse-web spiders, females live in silken tubes. The male seeks out a female tube and taps rapidly with palps and legs. If the female is not receptive, she will violently tug back. Lack of movement signals receptivity, and the male tears open the tube and enters.

Male spiders have a particular problem, as the transfer of sperm involves taking sperm packets and inserting them into receptacles on the underside of the female. This necessitates coming close to her jaws and, unless the female is willing or incapacitated, this is hazardous duty indeed.

Predictably, a number of behavioral patterns have evolved to deal with this problem. Male jumping spiders, *Euophrys frontalis*, seem to mesmerize their would-be mates. When he sights a female, the male snaps his front legs up and down and vibrates his white-fringed front palps, all the while slowly advancing. Females become quiescent through this behavior, and mating occurs soon after. The male crab spider, *Xysticus cristalus*, succeeds by seizing his mate by her front legs, wrestling her to the ground, and wrapping her in silk. He then crawls under her and deposits the sperm. *Pisaura mirabilis*, a wolf spider, is more subtle. He offers the female a wrapped fly, holding it aloft. As she advances, he leans farther and farther backward, so that eventually she is raised upward adjacent to him. As she grabs and eats the present, he slides underneath her.

The evolution of male self-preservation is brought to an aesthetically delightful turn among balloon flies (family Empididae). In the most primitive species, males are occasionally captured and eaten by females during early courtship. In somewhat more advanced species, the male captures an insect, seeks out a potential mate, and presents it to her. While the distracted female feeds on the gift, the male mates in relative safety.

A further refinement has evolved in some species. Although males capture prey, they do not actively seek out females. Rather, a large number of males swarm together, and females make the selection. The prey now seems to serve as an attractant for females.

More complicated behavior is seen in those species where the males attach threads or sticky patches to the gift prey. Originally, these helped to capture and subdue the struggling insect. In their more advanced stage, however, the wrappings have taken on a meaning all their own. Here the prey is no longer the prime female attractant and the male probably eats the prey himself. As we look at this species sequence, the prey becomes

175 Fifth Ave., NY 10010

smaller and smaller; in some species only a tiny, inedible fly is attached to the "balloon," and neither sex eats it. Now the gossamer, ornate balloon is what attracts the females. In its last stages, there is no prey at all involved in courtship, and the male presents the female with only an iridescent balloon as a token of his affection.

Some males do not have a defense against female predation, and in this respect, sex between praying mantids is unique. Upon recognizing a female, the male first stops, then slowly approaches. When sufficiently close, he jumps on her back and attempts to mate. Usually, the female reaches back and begins eating the male's head. Intriguingly, what we might consider antisocial behavior does not signal an end to copulation. Rather, the nervous system of the male mantid is such that head removal triggers off forceful copulating movements. Even if an approaching male is captured by a female and his head removed before he reaches her back, he will walk about in a circular path, eventually stopping next to her body. The headless individual then climbs up onto the female's back and mating commences. Although I personally would shrink from such heroics, we must surely acknowledge this manifestation of sheer determination.

Male insects face other problems unrelated to female behavior. For instance, male fireflies of the genus *Photinus* search at night for females, which flash a species-specific pattern. Unfortunately for these nocturnal males, female fireflies of the genus *Photuris* have evolved to mimic signals of female *Photinus*. When the male flies within reach of his putative mate, the impostor reaches out, grabs, and devours him.

*Gryllus integer*, a field cricket, has other difficulties. Males spend warm nights rubbing forewings together trying to attract females. However, the tachinid fly *Euphasiopteryx ochracea* is also attracted to the calling males. If a female fly finds the cricket, she will plant larvae on it. The larvae burrow into the cricket's body, and it dies soon after. Some male *Gryllus* seem to reduce their chances of parasitism while still enjoying the opportunity to mate. These are noncalling males that wait in ambush near a calling male and attempt to copulate with an arriving female before the crooner has an opportunity. In one species of katydids, calling males try to outwit noncallers by lowering the intensity of their call once the answering click of a female is heard, thus reducing the possibility of a noncaller locating the mating site.

Earlier, we discussed the prey-proffering balloon flies. Merely giving a prey gift, however, may not be enough to insure mating in some insects, for instance the scorpion-fly, *Bittachus apicalis*.

A comedy of errors begins with a male capturing a prey arthropod. After tasting it to ascertain its palatability, the male releases a female-attracting pheromone. When the attracted female comes near, she lowers her wings, a signal to the male to present the gift. If the gift is acceptable, mating occurs. (Ever the romantic, a male will usually try to regain the prey to use again after mating.)

However, capturing prey items is time and energy consuming, and hunters run the risk of being captured by predators such as spiders. Using behavior reminiscent of the play *Charley's Aunt*, many or perhaps most males will try to wrest away an already captured prey from other males by the insect version of transvestism. Males bent on pirating will approach gift-bearing males and lower their wings in a manner possibly identical to that of females. One study showed that in 67 percent of these deceptions, the gift-bearing male did indeed proffer the gift to the transvestite. After about two minutes the duped male realizes something is amiss and tries to regain the prize. The transvestite successfully retains the prey about 33 percent of the time. One assumes the gulled male then stalks off for a long, cold shower.

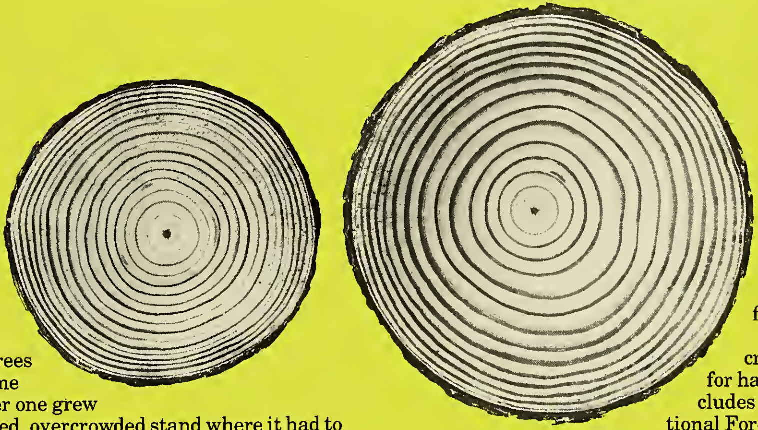
Perhaps the unkindest cut of all befalls the male of the damselfly species *Calopteryx maculata*. Females of this species store sperm and may mate more than once. To protect their parental investment, males guard females against attempted takeovers. If a male successfully takes a female away, he removes the sperm already stored, using a hair-lined, horn part of the penis. After removing most or all of his rival's sperm, he transfers his own.

Needless to say, damselfly paternity suits are beastly affairs.

*Milton Love is a research associate in the Department of Biology at Occidental College, Los Angeles.*

A report on the great American forest.

# Look what happens when Mother Nature gets a little help.



These log slices dramatically show the value of modern, scientific forest management. Both (shown 36% of actual size) are from trees of about the same age. The smaller one grew in an unmanaged, overcrowded stand where it had to compete for sunlight and moisture. The other is from a grove that was thinned to give the best trees room to thrive.

This is just one of many ways forest management can help meet a predicted doubling of domestic demand for wood and paper products in the next 50 years.

The forest industry has learned how to help Mother Nature grow more trees, faster, by applying scientific forest management techniques: encouraging natural regrowth, planting superior seeds and seedlings, fertilizing, protecting against disease and insects, thinning, watching carefully until time to harvest — then starting the cycle again.

## Demand keeps rising.

Forest management like this is vital because every year Americans need more homes, more paper products, more packaging and containers, more fuelwood, more of the thousands of other essential products that only the forest can provide.

So far, the country's commercial forest has been able to keep up with demand. (*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland—whether owned by individuals, government or the industry—that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.)

But trees aren't grown equally fast by all commercial forest owners. Though industry has made striking advances on its lands, productivity is lower on privately owned lands and seriously lagging in National Forests.

## Productivity not up to potential.

Overall, the U.S. Forest Service estimates average productivity of all commercial forestland is only 61 percent of potential. And at the same time, actual acreage in commercial forests keeps shrinking, as land is withdrawn for homes, highways and other needs of an expanding population.

So we as a nation still have a long way to go if our wood and paper products are not to become scarce and expensive.

If you'd like to be better informed on how important it is to keep America's forests productive, write American Forest Institute, P.O. Box 873, Springfield, VA 22150 for a free booklet, "The Great American Forest."

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

# Terrible Questions Provoke Great Responses

*A preliminary report on the responses to* Natural History*'s questionnaire, "You and the Ecology Movement"*

**by Luther P. Gerlach and Betty Radcliffe**

"This is a terrible questionnaire," protested one respondent to our 1980 "You and the Ecology Movement" questionnaire, "but the issues are so important that I had to answer." And along with the almost 4,000 others who have thus far responded, she did, indeed, give us her answers and was also part of the 32 percent who added comments in the space provided on the form. Many sent in news clippings or articles to help make their points. Some criticized the questionnaire for reflecting a bias they presumed to be *Natural History*'s, while others praised it as one more example of the good work the magazine is doing, for example, in raising environmental awareness. *Natural History* invited the authors to prepare the questionnaire and the follow-up reports. As authors, we claim complete responsibility. Luther Gerlach, the senior author, professor of anthropology at the University of Minnesota, collaborated with his research assistants in preparing the questionnaire—with Virginia Hine on the 1970 version and with Betty Radcliffe on the current one.

We have just finished coding the responses, and they are now being keypunched in preparation for computer analysis. To insure a timely final report, we will not be processing any further returns. We appreciate the cooperation of all who took the time to respond, especially those who listed the organizations that they support and those who added their comments. These will help us greatly in improving the questionnaire should it ever be republished or widely distributed again.

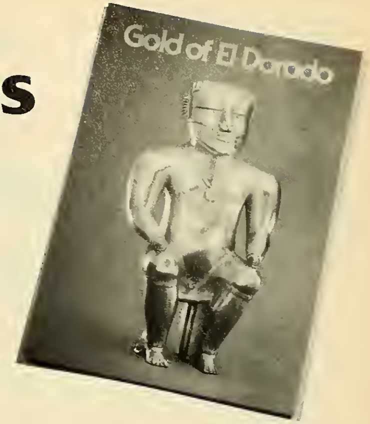
A common complaint of respondents was that even though we asked some good questions and really grabbed them with the issues, we did not provide enough choices for their answers. Many disliked having to select the best single response from three to seven options, for example, in question 17, which asked, "Which of the following seems to you the most desirable approach to achievement of a better, more adaptive energy and environmental future?" They pointed out that in resource and ecology issues—which are, indeed, survival issues—the situation is often not black or white but rather, many shades of gray, and they preferred to indicate this shading rather than take a polar position. Some felt that the options we gave them ranged nicely along the complexity of the issues, but asked why we didn't allow them to rank these options in order of importance. Others indicated that the proper answer to the resource and ecology problems we described was somehow way off our drawing board, deeply rooted somewhere else—that it lay, for example, in overpopulation, in the nature of our capitalistic system, in the way we have put a stranglehold on our capitalistic system, or in the growth of radical action on the left, action that some believed the questionnaire somehow encouraged.

What at first count seems to be a surprisingly large number of people felt that the ecology movement itself was one of our problems, along with a general drift to the left and away from the market economy. To one of the many who found great fault with the action of environmentalists, the only hope lay in the way "these antis" will be reduced in number as they drive their small and "unsafe" foreign cars. Is this just a bit of tongue in cheek? We begin to suspect, from the way these points are made time and again and from the additional news clippings sent, that there is a kind of rage here, a rage against environmentalists and those who block energy and economic development. On the other hand, others express a kind of despair that our way of life is destroying our environment and our wildlife. While a number of respondents criticized ecological organizations and a number stoutly defended their choice of personal efforts not linked to organizational membership or support, nearly two-thirds listed organizations in which they were active, some as many as thirty! It appears that, as individuals or through groups, *Natural History* readers are active in environmental concerns.

Many of the objections to our questionnaire are ones we ourselves would hold as anthropologists. Questionnaires are, after all, narrow instruments designed to produce large numbers of relatively easily analyzable responses to specific and narrowly defined questions with a limited range of answers from which to choose. Unlike some of our respondents, we do not view questionnaires as "quizzes" with right or wrong answers, as vehicles for educating people about a particular issue, or as instruments for self-analysis. Also, we are not interested in identifying respondents; we separated envelopes that would identify them and blacked out addresses stamped on the form itself. A significant advantage in the use of a questionnaire is protection of anonymity.

The main research tools of anthropologists are not questionnaires but in-depth interviews and observations in the field or "real life" situations. This gives us the shades of gray and the great variety of responses that so many respondents called for. During an interview, people can elaborate in detail, and in the process, they help us rework and expand our questions. On many of the responses to the questionnaire, we sensed the desire of people to be part of an interactive process; to get feedback from their feedback. During field research, observation of actual events enriches our understanding of the context of peoples' actions

# An Art Book That Took Centuries To Create



It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

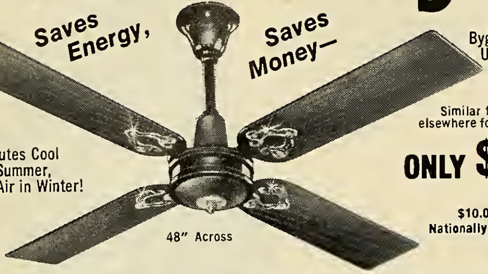
Famous Olde Time 5-Speed
Electric Ceiling Fan



The Charm of a Bygone Era—PLUS Up-to-the-Minute Practicality!

Similar to models selling elsewhere for $199 and more.

ONLY $89.

$10.00 Below Our Own Nationally Advertised Price.

Distributes Cool Air in Summer, Warm Air in Winter!

**LOWEST PRICE EVER!** A nostalgic wooden-paddle fan to grace your casbah. It's quiet-running, energy-efficient, and dramatically decorative. Perfect for home, shop, office.

Ceiling fans have been in use for over a hundred years—And with the energy crunch, they're more practical than ever. In summertime, air conditioners can be set warmer to save electricity, and you'll still get a refreshing cool feeling. In winter, the ceiling fan saves on fuel bills—recirculates warm air downward.

The all-season ceiling fan has metal base, trouble-free motor, weight-balanced, mahogany-finish, wooden blades, stylish brass trim, 5-speed wall-mounted switch. Easy to install; measures 48" across. (UL and CSA listed.)

**Z514SS40 . . . Ceiling Fan** ................$89.00

For the first time, collected in a single volume—the superb bird portraits of Edward Lear.

EDWARD LEAR'S BIRDS
Susan Hyman
Introduction by Philip Hofer

Because his career was cut short by failing eyesight, few people know that the master of limericks and Nonsense Verse was also a master of bird portraiture: Indeed, for sheer beauty, subtlety, and anatomical precision, his portraits rival the best of Audubon.

Now available in a single-volume American edition *for the first time ever,* this rare and stunning collection of 90 illustrations, including 40 in full color, reproduces nearly all of Lear's prints of exotic birds...and, of course, some deliciously witty Nonsense Birds, too.

Now that the secret's out, share it with a friend. It's sure to be the most delightfully surprising gift of the season.

$37.95 at bookstores or order direct, including $1.00 for postage from William Morrow, Dept. PAL-NH 105 Madison Ave., N.Y., NY 10016

and ideas. We certainly miss this when we work with questionnaires—both in designing them and in analyzing the results—and often feel as frustrated as some of our respondents. We recognize, however, that questionnaires are a useful instrument, and the willingness of the many respondents to fill them in showed that they feel the same way.

The 1970 questionnaire was based on field research on the ecology movement, and the rather substantial modification in 1980 was based on research on energy-conflict cases. While it narrowed the range of possible responses, the questionnaire did provoke many comments in the space we provided to elicit such open-ended additions. We could not possibly have conducted personal interviews with so many across so broad an area in so short a time.

One of the most controversial questions was number 17, in which we tried to evaluate the degree to which respondents held positions on what we considered to be an important national debate: the scale of energy technology and development and the level at which decision making about it should occur. Apparently it is not such a big debate after all. Some respondents were troubled with the way we lumped technologies instead of allowing them to choose a specific technology. Perhaps this is why many wondered, quite rightly, why we did not refer to nuclear technology, either fission or fusion, as an energy option. We do regret inadvertently omitting the word "nuclear" in choice 3 of question 17. Nuclear energy advocates were especially unhappy; fifty-eight wrote to point out this omission.

The absence of an opportunity in question 19 to choose overpopulation as the most critical ecological problem was perhaps the next most controversial item. Thirty people made a major point of this.

At least a fifth of the respondents commented in some detail on what they are doing to show their environmental concern. The majority fell into three groups, which we decided to code. People told how they were conserving energy and other resources, how they were working to preserve the environment and protect wild animals, and how they have made food-use changes, either "eating lower on the food chain" or growing more of their own food. Most of the actions reported are basic and rather ordinary,

but their sum total could be important. If, for example, this questionnaire response reflects the number of people who are stretching the life of their older cars, it is no wonder the auto industry is in trouble! Perhaps most interesting, they reported not only how they are making do with less, but also how they are becoming increasingly satisfied with this more frugal life style.

We look forward to seeing the computer results of this questionnaire: to see how they differ from 1970, to see with what attitudes about ecology the respondents begin the 1980s, and to analyze what this may portend. Our report on this will appear in a forthcoming issue. In the meantime, we wish to share with you a sampling of the interesting and provocative comments we received.

### *The Questionnaire*

Thank you for the opportunity, but it's painful to mutilate any issue of *Natural History*. Why could this not have been an insert or a blank page?

The theme of your questionnaire is to link a radical political philosophy with conservation—an unfortunate union and uncalled for.

As with most questionnaires, there is much that falls "between the two stools."

I really enjoy your magazine and am returning your questionnaire, but I do feel that the choices and wording of the questions and the narrow answers inhibit the expression of the true feelings of those of us who must work and live in the real world.

I am under the impression ambivalence or dichotomy in thought seems to catch up with you at times! Good luck!

Very poor exercise. Obviously prepared by social scientists or technically uninformed since questions 15–19 all miss the most important points and thereby force bias toward improper conclusions.

I feel many of your listed answers (like 14–25) . . . are technologically oriented without the human element.

This questionnaire is biased against atomic energy; and pro-pinko, moron rioters, Jane Fonda types, etc.

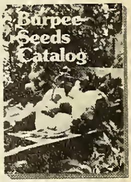
### *What Was Left Out*

I am shocked that a responsible organization would distribute a questionnaire like this with only one answering choice related to overpopulation.

An Ecology Quiz that doesn't mention population? How can this be? What is the sense in "educating" people via a

Burpee's new 1981 Seed Catalog-FREE

**Featuring new exciting vegetable and flower varieties for the home gardener.**



The new 184-page Burpee Catalog is a comprehensive planting and growing guide with over 1800 vegetables, flowers, fruits, shrubs and trees. Plus helpful hints from Burpee's horticulture experts on how to have a more productive garden. Send for your free copy today, and it will arrive in your mailbox in early January.

If you ordered from Burpee last year, you will automatically receive your free Burpee catalog in 1981.

quiz and leaving out the bedrock, basic reason why we are having an environmental movement and an ecological crisis in the first place.

I must protest the exclusion of the nuclear energy option from your list of energy alternatives in question 17. Among the presently viable methods of centralized energy production, nuclear fission is by far the *least* damaging to the environment.

Deregulation and market forces will solve energy problems.

I do these things [question 34 choices] but, I must admit, not primarily for environmental concern reasons.

I believe many persons who traditionally have been concerned about getting value for their money as a side benefit tend to protect the environment.

Does not adequately account for people who actively engage in ecological measures without organization membership.

### *Actions Taken or Considered*

I do not harass beneficial insects.

I hold large tracts of undeveloped land (at great expense).

I've turned down my thermostat. I wear synthetic furs.

It seems as if very few people are *really* interested in conserving. I even use my dental floss over and over again!

I am greatly in favor of modifying our home to make it more energy efficient, but I can't convince my parents.

Deny comfort and save? Okay. But where I live when the energy crunch first came, I and so many others saved electricity that the utility petitioned for a rate *increase* because so many less KWH had been sold, they needed more money. Got the increase too. So I'm stuck with my economies and paying more for them. Do you think I'm lying awake thinking of new ways to cut down?

Your questionnaire inspires me to actually join the Ecology Center in our town—doing instead of talking.

I would appreciate knowing ways to become more involved.

Unfortunately, I am too poor to have much to cut back on.

### *1970 and Now*

I was in favor of the ecology movement at first, but it has reached a point where our economy is being stifled by the movement. We are being reduced to a second-rate country by overly zealous opponents of coal and nuclear power, most of whom know nothing about either. Man is part of nature and has the right to improve his lot (within reason)! Be reasonable, not hysterical.

Ten years ago, I was marching and actively protesting. Now I'm older and don't think marching helps.

All of my environmental activities began in 1952 and ended in about 1970. By then I became convinced that mankind will not see the year 2000, no matter what we do now. It's too late, friends. You should have listened earlier.

### *On Activism*

Our hope is through action by existing organizations—church, state, political—not in creation of divisive splinter groups!

Too many individuals involved in environmental groups have very little technical knowledge about the various subjects they protest. This ignorance creates resentment among individuals who are knowledgeable in the technology involved with energy development and the environment.

Environmentalists are ruining America with their "no-spray" programs.

Let's be careful not to tear the fabric of our society in the name of ecology.

Are you trying to promote anarchy?!?!?!

We are a nation of LAWS. If you don't agree, please leave.

I find organizations to be as political and full of hot air as the opposition.

I would become an activist if my immediate environment was threatened by energy companies.

### *Eco-Philosophy*

I would like to state that this industrial society is doomed. The future is hopeless. What constantly amazes me is the amount of optimism. Do people have children because of optimism, or do they just need pets?

The poor nations won't wait for solar power.

Homo sapiens is a brilliant but doomed flash-in-the-pan.

Our problem is not really a shortage of energy sources. It is a shortage of faith in our ability to find alternate sources.

We have been given the stewardship of plants, animals—the environment. We must not use immoral techniques of "use and enjoyment." The central problem therefore is to determine what is a relationship of morality with the environment God has given us for our use and enjoyment.

This questionnaire overlooks the fact that all our problems are caused by the same basic attitude: personal unwillingness to subordinate personal rights to the general welfare. ☐

# Man, The Promising Primate

*The Conditions of Human Evolution*

Peter J. Wilson

How and why did animal nature become human nature? Writers in the field of human evolution have generally shied away from this most intriguing and fundamental question. In this new book, Peter Wilson confronts the problem through a bold application of logic to existing evidence on such basic human adaptations as promises and taboos, self-conscious thought, objective reasoning, symbolic kinship, and ritual behavior.

"A brilliant book, full of original insights and stimulating ideas."
—Ashley Montagu $12.95

# Splendid Isolation

*The Curious History of South American Mammals*

George Gaylord Simpson

In this book America's leading paleontologist traces the origins and histories of a group of animals that has intrigued scientists for centuries.

"In addition to the pleasure of pondering the lost mammals with so luminous a guide, this book provides many charming drawings, reconstructions of the animals based on the fossil record but literally fleshed out by the considerable talent of the artist, Judy Spencer."—*The New York Times Book Review*
43 illus. $17.50

# A World Like Our Own

*Man and Nature in Madagascar*

Alison Jolly Photographs by Russ Kinne

This book is a nature-lover's delight. Over 150 enchanting photographs of Madagascar's unique flora and fauna highlight a sensitive and eloquent description of life on this unusual island continent, where the economic and social needs of its human population are putting its rare wildlife precariously on the verge of extinction.
$29.95

# Cosmos, Earth, and Man

*A Short History of the Universe*

Preston Cloud

"A lively and thought-provoking account of the world we live in, how it got to be the way it is today, and what the future may hold."
—*American Scientist*

"An unequivocal *tour de force*, a major work that should be read by all who genuinely care about their planet."
—*The Chronicle of Higher Education*

# Chance Riches

*Perhaps our world really is only the result of randomness*

**by Stephen Jay Gould**

In literature, the idea of randomness is often coupled with chaos, lawlessness, or disorder to conjure up a vision of ultimate terror. In the *Essay on Man*, Alexander Pope evokes the image of an entire universe falling apart if its lawful order should ever be broken.

Let earth unbalanc'd from her orbit fly,
Planets and suns run lawless thro' the sky;
Let ruling angels from their spheres be hurl'd,
Being on being wreck'd, and world on world;
Heav'n's whole foundations to their center nod,
And nature tremble to the throne of God.

Pope's facile and hopeful solution simply banished the very idea of chance by a decree of faith:

All nature is but art unknown to thee;
All chance, direction which thou canst not see;
All discord, harmony not understood;
All partial evil, universal good.

Chance also got Darwin into trouble more than 100 years later when he granted it an important place in his evolutionary theory. Many critics, impelled by a knee-jerk negativism toward randomness, made no attempt to understand the strictly limited role that Darwin had awarded it. They argued: Darwin must be wrong; nature is so harmonious, animals are so well designed. This order cannot be the work of chance.

Darwin would not have disagreed. He constructed his theory in two parts, letting chance prevail in the first but strictly excluding it from the second for the conventional reason that chance could not, in his opinion, yield the order so prevalent in our world. In Darwin's theory, populations must first develop a large amount of heritable variation to provide raw material for the later, directing action of natural selection. Darwin viewed this pool of variation as random with respect to the direction of adaptive change—that is, if a species would be better off at smaller size, variation tends to arise with equal frequency at sizes both larger and smaller than the current average. The raw material for evolutionary change—and the raw material only—arises by a process of random mutation.

Natural selection then enters for the second part, and it acts as a conventional, deterministic, predictable directing force. Natural selection fashions the raw material of variation by preserving and fostering individuals that vary in adaptive directions. In our hypothetical population, small members will, on average, rear more successful offspring. Slowly, but inexorably, the average size of individuals in the population will decline.

Darwin expressed himself with admirable clarity, yet critics have been misunderstanding this fundamental point for more than a century, from the Rev. Adam Sedgwick (Darwin's geological mentor, not a dogmatic and antiscientific theologian) to Arthur Koestler. The litany is ever the same: Darwin must be wrong; order cannot arise from chance. Again, Darwin never said that it could. Chance only produces raw material; natural selection directs evolutionary change.

Evolutionary theory is now stirring from the strict Darwinism that has prevailed during the past thirty years or so. While critics have not seriously challenged Darwin's mechanism on its primary turf of explaining adaptation, they have rallied around a claim for pluralism. Must all evolutionary change be viewed as adaptation and ascribed to natural selection? Randomness has become a central focus for the critics because Darwin's strict dichotomy seems to be breaking. Randomness may not act only in generating variation; it may be an important agent of evolutionary change as well. The specter of chance is now truly intruding where Darwin's critics had falsely detected it before. Given both the surpassingly poor reputation of randomness in general (including the fear that it often generates), and the specific Darwinian tradition of limiting its role to the production of raw material only, this development in evolutionary theory is both exciting and, to many, disturbing.

I should enter some disclaimers, if only to reduce disturbance. Randomness is making its bid as an agent of evolutionary change, but it is not threatening natural selection in the realm of adaptation. The beauty and aerodynamic efficiency of a bird's

# Clearing the Nation's Air

## What the chemical industry is doing to help clean up the air you breathe

**Today, almost all of our industry's plants meet or exceed Environmental Protection Agency clean air requirements. But we're not stopping there. Here are some of the ways we're helping America breathe easier:**

### 1. Committing billions to clean up

The chemical industry is investing more than any other U.S. manufacturing industry in fighting pollution, according to the U.S. Census Bureau. Since 1976, we've doubled our investment in air pollution control equipment. By the end of 1979, this commitment exceeded $2.6 billion. We are also investing millions of dollars in environmental research. The expenditures for one research program alone are expected to exceed $9 million by the end of 1980.

### 2. Upgrading plants and processes

New plant construction includes sophisticated equipment and technology. Older, existing plants are being refitted with additional equipment to improve emission control and meet environmental requirements. We're also finding ways to recycle emissions to create useful raw materials.

### 3. Trapping particulates more effectively

A scrubber at one company helps trap more than 1,300 tons of particulate sulfur each year. Electrostatic precipitators help reduce fly ash emissions by nearly 100 percent. "Baghouses," which operate like household vacuum cleaners, also help keep dusts and solid particles from contaminating the air.

### 4. Capturing vapors with new technology

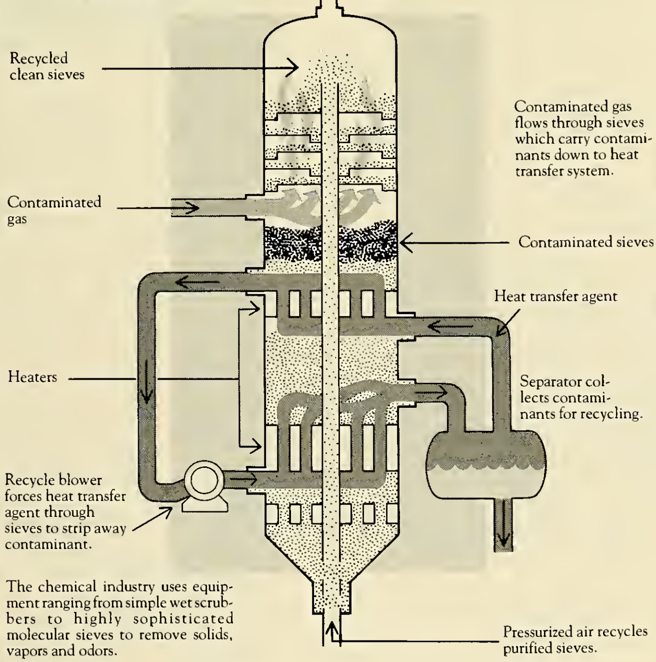
Research is helping us find new and better ways to control gaseous wastes. For example: a highly specialized molecular sieve recovers waste sulfur dioxide from the vent gas of sulfuric acid plants for recycling into the acid-making process. Special incinerators help control odorous gases. We've created compounds which can trap specific kinds of pollutant molecules.

### 5. Getting more employees involved

We have more than 10,000 employees whose sole job is to operate, maintain and monitor pollution control equipment. And we add to this number each year. At one facility, employee programs encouraged ideas which helped eliminate 75,000 tons of air pollutants each year.

*For a booklet that tells more about what we're doing to protect the environment, write: Chemical Manufacturers Association, Dept. GL-11, P.O. Box 363, Beltsville, Md. 20705.*

Molecular Sieve Process
To Fight Air Pollution



Clean, treated gas
Recycled clean sieves
Contaminated gas flows through sieves which carry contaminants down to heat transfer system.
Contaminated gas
Contaminated sieves
Heat transfer agent
Heaters
Separator collects contaminants for recycling.
Recycle blower forces heat transfer agent through sieves to strip away contaminant.
Pressurized air recycles purified sieves.

The chemical industry uses equipment ranging from simple wet scrubbers to highly sophisticated molecular sieves to remove solids, vapors and odors.

wing, the grace and good design of a fish's fins are not lucky accidents. Also, I use the specific meaning that "random" has long maintained in evolutionary theory: to describe changes that arise with no determined orientation. I do not use it as a general metaphor for chaos, disorder, or incomprehensibility (more on this later).

Evolution operates at three major levels: populations change as the frequency of certain genes increases or decreases among their members; new species arise by the splitting of descendant populations from their ancestors; and evolutionary trends occur because some species are more successful than others in branching and persisting. Randomness is challenging the determinism of natural selection as a cause of evolutionary change at all three levels.

*The genetic structure of populations.* When natural selection operates in its usual way, genetic variation is reduced: the fit arise, in part, by the elimination of the unfit. The total amount of genetic variation in a population should represent a balance between the addition of new variation by mutation and the removal of unfit variants by natural selection. Since we have stores of data on rates of mutation and selection, we may predict the upper limit of variation that a population can maintain *if* selection acts upon all genes.

Techniques for measuring the amount of genetic variation in natural populations have only been available for the past fifteen years. Their first and primary result came as a surprise to many geneticists: most populations maintain too much variation for the usual claim that all genes are scrutinized by natural selection.

To be sure, natural selection does not always eliminate. In some cases, it may act to increase or maintain genetic variation. The most common mode of maintenance is called "heterozygote advantage." Suppose that a gene exists in two forms, a dominant *A* and a recessive *a*. In sexual species, each individual has two copies of the gene, one from each of its parents. Now suppose that the mixture, or so-called heterozygote *Aa*, has a selective advantage over either pure form, the double dominant *AA*, or the double recessive *aa*. In this case, selection will preserve both *A* and *a* by favoring the heterozygote *Aa* individuals.

But even these modes of preserva-

tion have their limits, and many geneticists feel that populations still maintain too much variation for selective control. If they are right (and the issue remains under intense debate), then we must face the possibility that many genes remain in populations because selection cannot "see" them, and therefore cannot either mark them for elimination or remove other variants by favoring them. In other words, many genes may be *neutral*. They may be invisible to natural selection and their increase or decrease may be a result of chance alone.

Since "change of gene frequencies in populations" is the "official" definition of evolution, randomness has transgressed Darwin's border and asserted itself as an agent of evolutionary *change*. (This process of random increase or decrease of frequency is called "genetic drift." Contemporary Darwinism has always recognized drift, but has proclaimed it an infrequent and unimportant process, mostly confined to tiny populations with little chance of evolutionary persistence. The newer theory of neutralism suggests that many, if not most, genes in large populations are maintained by random factors.)

*The origin of species.* Species are defined as populations that are reproductively isolated from all others. Placed in contact with other populations, a true species will maintain itself as a separate evolutionary entity and will not amalgamate with another population by hybridization. The key question for the origin of new species then becomes, How does reproductive isolation evolve?

In the traditional view, an ancestral population is split by a geographical barrier (continents may drift apart, mountain ranges rise, or rivers alter their course, for example). The two descendant populations then evolve by natural selection to fit the local environments of their separated places. In due time the populations become so different that they will no longer be able to interbreed, should they reestablish contact. Reproductive isolation is a byproduct of adaptive evolution by natural selection.

During the past decade, the exclusivity of this mode has been challenged by a variety of new proposals advocating an interesting twist or reversal of perspective. They all argue that reproductive isolation can arise rap-

idly as a result of historical accidents with no selective significance at all. In this case, reproductive isolation comes first. By establishing new and discrete units, it provides an opportunity for selection to work. The ultimate success of such a species may depend upon a later development of selected traits, but the act of speciation itself may be a random event.

Chromosomal speciation, the most popular of these models, deserves (and will soon receive) a column in itself, but for now, merely a sketch and an example. Taxonomists have discovered that many groups of closely related species do not differ much in form, behavior, or even general genetic composition. But they do display outstanding differences in the number and form of chromosomes, and these differences produce the reproductive isolation that maintains them as distinct species. An obvious, and old, hypothesis would suggest that each new species arises when a major chromosomal change occurs by accident and manages to establish a new population.

But this hypothesis suffers an obvious difficulty: the major change arises in a single individual. With whom shall it breed? The hybrid offspring of this mutant and a normal member of the population will almost surely be at a strong selective disadvantage. The mutation will therefore be swiftly eliminated.

Recent work on the structure of populations indicates that some reasonably common forms of social organization might facilitate the origin of new species by rapid and accidental chromosomal change. If populations are "panmictic," that is, if each female has an equal chance of breeding with each available male, then the chromosomal mutant cannot spread. But suppose that populations are subdivided into small groups of kin that breed exclusively with each other for several generations. Suppose also that these kin groups are harems, with a dominant male maintaining several females, and with brother-sister mating among the offspring.

If a chromosomal mutation arises in the dominant male, all his children will carry both the mutant (from their single father) and the normal form (from their various mothers). They will probably be at a strong selective disadvantage relative to normal offspring in other harems. But this may not matter, especially if they have limited contact with other groups. The

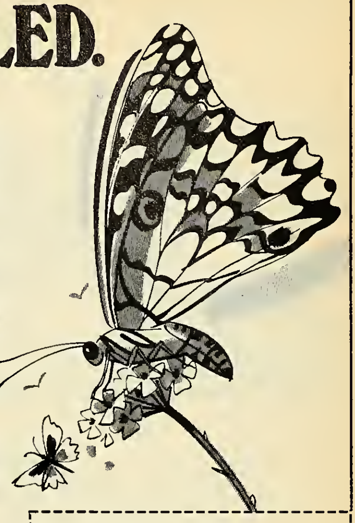
offspring may die at a higher rate, but we only require that a few survive to mate with their similarly afflicted siblings.

One-fourth of these second generation offspring will be "pure" and contain two copies of the chromosomal mutation. If they can recognize and mate preferentially with each other in the next generation, all offspring will be pure mutants and members of a new species already (if they continue to mate with each other and if any hybrid offspring with normal forms suffer a strong selective penalty). The new chromosome is selectively neutral; it provides neither advantages or disadvantages in itself. By establishing itself rapidly and accidentally in a small group, it permits the origin of a new species, again by chance. The new species may require substantial adaptive retooling for its subsequent survival, but this is a different, and later, matter.

My colleague Guy Bush, of the University of Texas, tells me that horses provide, circumstantially at least, a strong case for chromosomal speciation. They all maintain the harem structure of kin breeding. Their eight living species (two horses, two asses, and four zebras) all look and act pretty much alike, despite some outstanding differences in external color and pattern. But their chromosome numbers differ greatly and surprisingly, from thirty-two in one of the zebras to sixty-six in that paradigm of the unpronounceable, Przewalski's wild horse.

*Major patterns of rise and fall in the history of life.* Many readers might be willing to accept chance at the smaller levels. A bit of slop for some "invisible" genes within populations, an accidental species here and there. But surely conventional reasons rule the grand ebb and flow of major groups in the history of life. Trilobites must not be as good as the "advanced" arthropods, shrimps, and their allies that now populate our seas. The hordes of brachiopods from times past must have been pushed out by other creatures, clams in particular, that look like them but work better. Dinosaurs must have been bad at something that mammals can do. At this level, natural selection must reign and life must improve.

The key to recognizing the essential fallacy of this argument lies in the facts of mass extinction. If groups slowly replaced other groups, some



UNSPOILED.

There are few places left on earth that are unspoiled. Sri Lanka is one of them. Once known as Ceylon, Sri Lanka has Asia's best game preserves. 200 species of animals, 425 kinds of birds and hundreds of square miles of leopard, elephant and sambur.

The wild flowers of Sri Lanka include a dazzling display of orchids. And where else could you find 600,000 acres of tea gardens on misty mountains?

There are 75 ways you can tour Sri Lanka. Ranging from 3 to 21 days. Accommodations begin at $5. Deluxe sells for $45. Never has your dollar worked harder. From shopping to sightseeing.

In our ancient cities, you can enjoy frenetic festivals that reflect the unspoiled nature of a culture which dates back 3,000 years.

Whether your visit is pleasure, business or a convention, our unspoiled country will spoil you. Just one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color flyer and tour digest that includes special airfare.

A handsome collection of wildlife paintings and a self-portrait of the man who created them...

Observations of Wildlife

by PETER SCOTT

With a Foreword by H.R.H. The Duke of Edinburgh, K.G., K.T.

Sir Peter Scott—recently named Master Wildlife Artist 1980—has achieved fame as a painter of wildlife, as the founder of the Wildfowl Trust, and as one of the world's leading conservationists. Many of Scott's finest works are included here along with some fascinating pages from his sketchbooks, and in the text he discusses his efforts to save the earth's natural heritage. With 100 illustrations, 36 in full color. $19.95

A Cornell/Phaidon Book

At fine bookstores or from
CORNELL UNIVERSITY PRESS
P.O. Box 250, Ithaca, New York 14850

Detail from Age of Reptiles

Dinosaurs and Mammals from Yale

The original 110-foot "Age of Reptiles" mural in the Great Hall of the Peabody Museum took four and a half years to complete and won the artist, Rudolph F. Zallinger, a Pulitzer Prize. The mural depicts thirty dinosaurs in six successive eras of earth history. The 60-foot "Age of Mammals" mural presents the fauna and flora of the Paleocene to the Pleistocene era. Beautiful full-color reproductions of these unique masterpieces are available in two sizes. The larger format—over 9 feet long—is a lithographic print on a heavy, durable paper. The smaller version (6 feet long) is printed on glossy paper. Illustrated guidebooks are available for each mural.

To order your copies of these beautiful reproductions, fill in the coupon below and send with your payment to:

gaining in species over millions of years while others lost just as steadily, a scenario of selective control might seem irresistible. But most groups disappeared during the episodes of mass extinction that have punctuated the history of life. This fact is not news. It has been acknowledged for decades but explained away with an assumption that differential mortality at extinctions must have a selective basis. The groups that roared (or even squeaked) through a holocaust must have survived for a reason. They were the tough guys, the good competitors. But some recent data on the extent of mass extinctions must call this comforting explanation into question.

The granddaddy of all extinctions occurred about 225 million years ago at the end of the Permian period. (We don't know why, although the coalescence of all continents at about the same time must have set the basic stage.) By wiping out many groups, permanently debilitating others, and allowing some to pass through relatively unscathed, this great dying set the fundamental pattern of life's diversity ever since. But how profound was the Permian extinction? An old and familiar figure states that half the families of marine organisms (52.0 percent to be exact) perished at that time. But families are taxonomic abstractions. What does 52 percent of families mean for species, nature's real units? (Inconsistent taxonomic practices and an inadequate fossil record prevent the counting of species directly. Families, as bigger units, are harder to miss.)

We can be sure that a removal of half the families requires the death of a much greater percentage of species. A family is not gone until all its species die, and many families contain tens or hundreds of species. The extinction of most individual species does not wipe out a family, just as, for example, the random excision of a single entry in a telephone directory rarely removes the name entirely—you'd have to bump off a lot of Smiths. How many species must die before 50 percent of families are gone?

David M. Raup of Chicago's Field Museum has recently considered this question (*Science*, vol. 206, 1979, page 217). The problem is not so easy as it might appear to be. If all families contained about the same number of species, then a simple formula would suffice. But variation is enormous. Many families contain only a single species. In this case, removal of the species also wipes out the family. Phone books contain their Zzyzzymanskis as well as their Wongs. Other families contain more than 100 species. We must know the empirical distribution of species per family before we can make a proper estimate. And we cannot construct an empirical distribution for Permian families because we cannot count the species directly.

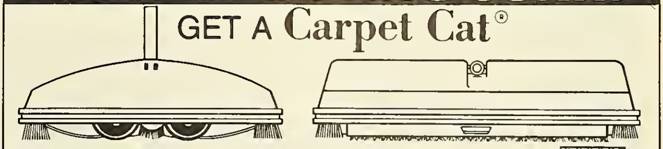
Raup therefore made tabulations for a group that we do know well, the echinoids, or sea urchins. Echinoids include 894 species distributed into 222 genera and 40 families. How many species must, on average, be removed at random in order to eliminate 52 percent of the families? Raup considered this question both empirically and theoretically and came up with the astounding figure of 96 percent. If the rest of life maintains a distribution of species within families similar to the echinoids—and we have no evidence for major differences in the pattern—then the Permian debacle might have wiped out all but 4 percent of species.

Since estimates of living species in the late Permian range from 45,000 to 240,000, a removal of 96 percent would leave but 1,800 to 9,600 species as guardians of life's continuation. Moreover, as Raup argues, we have no strong evidence, despite intensive and specific search for it, of selectivity in the Permian extinctions. The debacle did not seem to favor any particular kind of animal—bigger creatures, inhabitants of shallow water, more complex forms, for example.

I am not entirely persuaded by the 96 percent figure. Echinoids may not be a good model for all of life. More important, Raup is assuming that the 52 percent figure is not artificially inflated by biases in the fossil record. We know, for example, that late Permian marine sediments are relatively rare and we may be missing some families that lived then simply because we have so few places left to look for them. Nonetheless, even the most conservative figures indicate a removal of 80 to 85 percent of all species.

I think that we must therefore face an unpleasant fact. If anywhere near 96 percent of all species died, leaving as few as two thousand forms to propagate all of later life, then some groups probably died and others survived for no particular reason at all. There are few defenses against a catastrophe of

TIRED OF BUYING JUNK?
GET A Carpet Cat®



The CARPET CAT is built with care by people who make nothing else, for people who believe household appliances should last a lifetime. We also think appliances should be noiseless, convenient, pretty, efficient and require no electricity.

If you feel the same way, you're going to love a non-electric CARPET CAT floor and carpet sweeper. We believe it is the lightest, strongest, most efficient and convenient appliance of its type on earth. In the past 6 years, thousands of commercial users worldwide (airlines, hotels, restaurants, etc.) have confirmed our belief by demanding only our floor sweepers. A CARPET CAT weighs under 3 pounds, is only 9 inches wide and works as well on a bare floor as it does on carpet. It picks up sugar, sand, pet hairs, paper clips, ashes and much more. Who really needs a vacuum cleaner?

Yes, it looks like an old-fashioned "carpet sweeper" (except it is far smaller and about ⅓ the weight), but there the similarity ends. The CARPET CAT is patented and based on entirely new technology. Its natural hog bristle brush will outlast synthetics by about 3 to 1. It should last a lifetime if properly cared for in ordinary household use. The CARPET CAT'S baked enamel surface wipes clean with a damp cloth. Horse hair corner brushes clean right up to the wall, and the whole sweeper can be hung up in 2 inches of wall space. EVERY PART IS REPLACEABLE AND CARRIED IN STOCK.

If you can find any other sweeper that can make the above claims, BUY IT. We are sure you can't, so we want you to try our CARPET CAT.

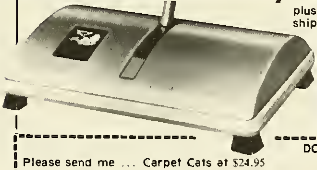
Pick up unexpected messes in seconds.

Clean stairs quickly and easily.

Reach hard-to-get-at-places.

THE CARPET CAT: *Only* $24.95
plus $3.50 for ship./hand.

NO NOISE, NO HOSE, NO ELECTRIC CORDS



**30-DAY MONEY-BACK GUARANTEE**
If you decide the CARPET CAT is unsatisfactory FOR ANY REASON, simply return it to us within 30 days and we will refund the entire purchase price. You can't lose. **DORSAY, 142 MacArthur Ave., Dept. 625229, Garfield, N.J. 07026**

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers…rain forests, mountains, and tundra…seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

Shadow of the Hunter

Stories of Eskimo Life
RICHARD K. NELSON

These stirring tales – all fiction but based on a collage of what is real – follow a group of Eskimo hunters and their families through the cycle of the Arctic year. They celebrate the humor and endurance of a people whose genius is for survival in a land of challenge and adversity. $12.50

University of Chicago Press

such magnitude, and survivors may simply be among the lucky 4 percent. Since the Permian extinction set the basic pattern of life's subsequent diversity (no new phyla and few classes have originated since then), our current panoply of major designs may not represent a set of best adaptations but a group of fortunate survivors.

If we must admit randomness as an important agent of evolutionary *change* at all levels, what shall we make of it? Shall we surrender to despair and proclaim the history of life both chaotic and unknowable? Such a solution might embody Pope's equation of chance with disorder, but it would represent a great misunderstanding of the meaning of randomness, for two reasons.

First, chance may represent a good description of events at one level but not imply that the events are truly uncaused. Take the classic random event, a coin flip or the throw of a die. I imagine that each flip has a determinable outcome if we could (as we cannot) specify all the multifarious factors that enter into it—height above ground, force of the flip, initial side up, angle of first contact with the ground, for example. But the factors are too numerous and not under our control; an equal chance for each possible outcome is the best prediction we can make in the long run.

Perhaps the Permian extinction worked like a set of dice with few winning outcomes. Each species became extinct for a conventional local reason—this pond dried up, that estuary became too salty or suffered an invasion of a particularly efficient predator. But the reasons are so numerous and so beyond our ken that an equal chance for the removal of each species becomes a good prediction for the overall outcome.

Only in this way could many of the inventors of probability theory stomach their own creation, for they were conventional believers in deterministic causation and convinced theists unwilling to debar purpose from the world. Charles Bell, author of a famous work on the human hand as a reflection of God's wisdom through its intricate design, wrote in 1833:

> We say, in common parlance, that the dice being shaken together, it is a matter of chance what faces they will turn up; but if we could accurately observe their position in the box before the shaking, the direction of the force applied, its quantity, the number of turns of the box, and the curve in which the motion was made, the manner of stopping the motion and the line in which the dice were thrown out, the faces turned up would be a matter of certain prediction.

This explanation may be comforting, but I think we must face a second possibility. Perhaps randomness is not merely an adequate description for complex causes that we cannot specify. Perhaps the world really works this way, and many happenings are uncaused in any conventional sense of the word. Perhaps our gut feeling that it cannot be so reflects only our hopes and prejudices, our desperate striving to make sense of a complex and confusing world, and not the ways of nature.

What solace, then, can we have if solace we need. An answer, I believe, lies in rejecting another traditional belief, Pope's false equation of chance with a host of fearful cognates: disorder, chaos, lawlessness, unpredictability, and destruction. For contrary to popular belief, random means none of these. It may not, in the case of Bell's dice, imply a lack of causation. And even if it does in many cases, the result of a random process is not necessarily unpredictable disorder.

Random processes can yield highly predictable order. We have an elaborate theory for predicting the results of coin flipping, the archetypical random process. Suppose we flip six coins at once, over and over again. We can predict how many times the most common result of three heads and three tails will occur, and how many times the rare event of all heads or all tails will arise (one in sixty-four for each or one in thirty-two for either).

Admittedly, this is predictability of a different order. It works only for repeated trials in the long run. We can assign a probability to each individual flip, but we cannot determine a specific outcome. Nonetheless, the end result is ordered and predictable. Does not this kind of randomness offer sufficient comfort against the threat of chaos? Does it not even make for a more intriguing world? After all, it is this kind of chance that gives our own lives, and the course of human history, so much richness and interest. Call it by its older names of fortune or free will, if you like. Shall we deny a similar richness to the rest of nature?

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

PRIVACY
BEGINS
AT HOME

Personal privacy.

Everyone wants it. Everyone believes in it. And with so much personal information being stored in computers and other files, it's been of continuing concern to us at IBM.

So, a number of years ago we began to examine how personal information was being handled in our own house.

Actually, our record was pretty good. But it wasn't perfect.

We discovered that we were collecting some information about people which didn't really relate to their jobs. And we concluded that one excellent way to protect people was to collect less information about them.

So, we purged our files of non-essential data. And we stopped asking job applicants things such as age, where a spouse worked, credit references, etc.

We ask only what we need to know to run IBM, and only people who need to know it can see it. Information that's stored in computers is further protected by electronic safeguards built into the system.

What we've done so far isn't the answer for everyone.

But it begins to deal with the question. IBM®

*A few years ago,* The Harvard Business Review *published an examination of the program to safeguard personal privacy inside IBM. If you'd like a copy, write to:*

*The Classic Car Museum presents*

# The world's great classic cars silver miniatures

*The complete collection of officially recognized international classics — each portrayed in brilliant micro-detail*

Shown actual size.

---

*You can acquire these superb sterling silver miniatures — at just $9.50 each — by entering your subscription now.*

---

At first glance, your eye is attracted by the captivating glow of silver. Fascinated, you look closer . . . and the lines of an automobile begin to take shape. Then, you place the silver miniature under a magnifying glass — and there, in remarkably clear and precise detail, is one of the world's great classic cars!

This is the excitement that awaits you in every issue of *The Official Classic Cars Silver Miniature Collection*, as you discover the intriguing world of the minted miniature. A world that combines the beauty of solid sterling silver with the fascination of meticulous detail in the tiniest area . . . and the precision of a perfectly formed yet minute work of craftsmanship.

Issued by The Classic Car Museum and produced by The Franklin Mint, this extraordinary new collection will consist of 63 such carefully crafted miniatures. Each will portray – with *complete accuracy and authenticity* – one of the world's greatest, most beautiful and most distinctive luxury automobiles. And, to assure its rarity, the collection is being made available *solely* by direct subscription, and *only* for a limited period of time.

### The finest and most luxurious cars ever built

The classic car has been officially defined by The Classic Car Club of America as a "fine and distinctive American or foreign car built between 1925 and 1948." Yet out of the thousands of cars that have been produced over the years, *only 63 marques* qualify as true classics. And *each* of these marques will be represented in this collection by one notably distinguished model. Among them will be:

*The 1928 Isotta Fraschini Landaulet Cabriolet*, Italy's most coveted luxury car – and a favorite of wealthy European families.

*The 1927 Bugatti Royale*, often called the "thoroughbred" of the motoring world. A perfect combination of craftsmanship, outstanding design and mechanical excellence.

*The 1929 SSK Mercedes Benz.* A real eye-stopper because of its elegant styling – and distinguished for its performance.

*The 1939 V-12 Packard.* Originally owned by the famous actor Errol Flynn, it features a leather top, horse-hide upholstery, fur flooring, hydraulic brakes and concealed aerial.

And such equally famous marques as the Lincoln, Bentley, Auburn, La Salle, Marmon, Peerless, Stutz, Chrysler, Renault, Talbot, Mercer – *every one of the 63 officially recognized international classics.*

### Flawlessly crafted works in miniature

Each superb sterling silver miniature will recapture, with astonishing accuracy and exacting detail, the special features that set one historic car apart from all others. You will actually be able to see and identify every one of the spokes on the wheels of the 1934 Duesenberg. The ornate hood ornament on the 1926 Rolls-Royce Phantom I. The windshield wipers on the 1938 Lincoln Coupe. Even the different car *emblems* can be clearly seen!

So that the design of each car can be fully appreciated, moreover, the silver miniatures will be minted in an unusual *oblong shape*. This will allow every car to be displayed in *two* different ways: from the front *and* from the side.

To assure complete accuracy, The Franklin Mint obtained permission from the owners of the cars represented to examine these great cars at first hand. Thus, each silver miniature is a *totally authentic* portrayal of one of the great classic cars.

### Special magnifier included

To enable subscribers to study each silver miniature in close-up detail, *a special magnifying glass* will be sent at no additional charge with the first shipment. This precision magnifier is mounted on a stand for easy and effective use. And it's fully collapsible as well, so it can be safely stored in its own protective cover when not in use.

Furthermore, each subscriber will receive a handsome collector's case, custom-designed to house and protect all the silver miniatures. This finely crafted case provides a convenient and attractive means for displaying the collection – and enjoying each individual miniature.

### A miniature treasure in silver . . . at a guaranteed price

You will be able to build the complete collection of silver miniatures conveniently – and at surprisingly low cost. Each month, beginning in January, you will receive one new miniature for your collection. The price for each sterling silver miniature is just $9.50. And this favorable price will be *guaranteed* to you for the entire subscription period – a most significant guarantee in these days of constantly fluctuating prices.

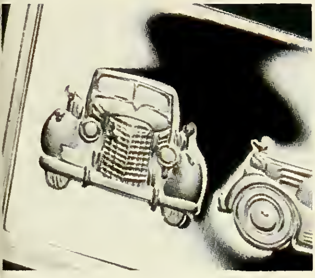
By authority of The Classic Car Museum, *The Official Classic Cars Silver Miniatures* will be issued in limited edition and by direct subscription only. The number of complete sets to be issued will be permanently limited to the exact number of subscriptions entered by the end of 1980.

### Subscription deadline: December 31, 1980

Whether you are an admirer of beauty in silver . . . a person who is intrigued by intricately detailed works of art in miniature . . . or a devoted car buff, this collection

will provide great pleasure and satisfaction for you and your entire family, throughout the years to come.

To acquire *The Official Classic Cars Silver Miniature Collection*, you must mail the application at right by December 31, 1980. No payment is required at this time – but be sure to act by December 31st at the very latest.



1938 Cadillac Convertible silver miniature illustrated above is approximately five times actual size to show fine detail.

# Ireland's Bountiful Bogs

*Long a source of fuel and building materials, Ireland's bogs are also an archeological treasure house*

by Sharon Bohn Gmelch and George Gmelch

You stand looking out over a gently undulating sea of reeds, sedges, moss, and heather dotted by small islands of water. In spring this "sea" shimmers in green and gold; in summer, white cotton sedge flutters over its surface; in autumn it is mantled in russet and red. You move and the ground quivers underfoot. Only the scraw, the upper crust of fibrous turf and living vegetation, prevents you from sinking. Bog is 96 percent water; whole milk contains more solids.

Bogs cover three million acres, or roughly one-seventh, of Ireland's land surface. Found in almost every county, they are especially common along the western seaboard and in the broad plains of the midlands. Ireland's greatest natural resource, the bog is a source of fuel, building materials, and

Ronny Jacques, Photo Researchers

other products. But as a reminder of Ireland's poverty-stricken past, when the bog was nothing yet everything, it is also the country's most verbally abused feature. A "bog trotter" is a country bumpkin. To be a "sod" is to be thick and ignorant.

Since prehistoric times, turf from the bog has been cut for fuel in treeless parts of Ireland—in upland areas and along the windswept western coast. In other areas it was not commonly used until the sixteenth and seventeenth centuries when the British systematically cut down Ireland's remaining native forests: in the sixteenth century, to make military operations against elusive Irish "rebels" easier and to clear the land for farming and colonization by English and Scottish planters loyal to the British Crown; in the seventeenth century, for profit. The new landlords sold timber for use in the housing, shipbuilding, iron-smelting, and leather industries. Irish lumber also went to Welsh coal mines for pit props and to the Spanish and French wine trade for barrel staves. By 1700 the forests had been replaced by grass and weeds, and the land was used for rearing sheep and cattle. Turf became vital for domestic heating and cooking all over the country. It also became important in early industry. In the eighteenth century linen bleachers and brick makers used huge quantities of turf as fuel.

The basic methods of hand cutting, or winning, turf from the bog have changed little over the centuries. As soon as the crops are planted and dry weather begins, usually in April or early May, neighbors and family groups enter the bog to begin work. Traditionally, when almost all the land was held in common, the work was cooperative—neighbors gathered voluntarily to work one day for each of their number in turn. Today, each family has its own turf bank, or cutting face, but two or three families often pool their labor. Some manage to cut a year's supply of turf in two long days of work, but most people spend a week at this task.

Before any turf can be dug, the bog or section of bog has to be drained by digging channels to the nearest stream or brook. Then the cutting face can be opened. First the surface scraw, or parings, of coarse grass, heather, and moss is removed. Typically, a broad spade and sharp knife are used

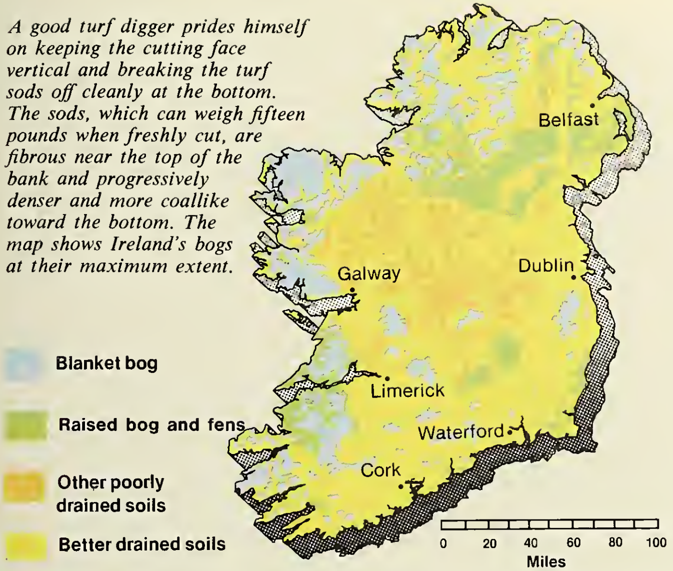
*A good turf digger prides himself on keeping the cutting face vertical and breaking the turf sods off cleanly at the bottom. The sods, which can weigh fifteen pounds when freshly cut, are fibrous near the top of the bank and progressively denser and more coallike toward the bottom. The map shows Ireland's bogs at their maximum extent.*



Joe LeMonnier

to peel back and cut the scraw. In some areas the scraw is burned to make its removal easier, but this practice is risky since fires can easily burn out of control. Permits are required in areas bordering government forestry projects.

Turf diggers now cut the prepared turf bank vertically from the top, using a method known as underfooting and a specialized spade called a slane (*sleán* in Irish Gaelic). Most slanes have a triangular wing set at right angles to the bottom of the narrow blade so that a complete sod can be detached with each stroke. While the exact shape and style of slane vary from one part of the country to the next—there are at least twenty regional styles—the one uniform characteristic is its light weight. Since a single water-saturated turf sod can weigh up to fifteen pounds when cut, slanes are made as light as possible. In some deep, lowland bogs, turf diggers use a different method, called breasting, in which they face the bank and cut horizontally into its side.

Most of the work is done in silence. Digging is hard, and no one wants to waste energy on talk. An experienced slanesman works with rapid precision, slicing the turf into uniform sods and rhythmically pitching them out of the bank. Great importance is attached to "keeping a straight face," that is, keeping the cutting bank vertical, and a poor digger is referred to as a clod cutter. Pride is also taken in ringing, or cleanly breaking, the turf sods off at the bottom. This is hardest to do when cutting the first layers of turf, which are looser and more fibrous. As the lower levels of the bog are reached, the turf becomes progressively darker, denser, and hotter burning. Freshly cut turf has the appearance and consistency of black butter. Ideally, a season's supply should contain both quick-firing top turf and coallike bottom turf.

Under favorable conditions, experienced slanesmen can cut a ton of turf in a single day. The freshly cut sods are caught by a barrow-man, who spreads them in a single layer on the surface of the bog immediately next to the cut or takes them by barrow or, more commonly today, by tractor and sledge to a special area, or spread field. There they lie for two weeks to dry in the wind and sun. The second stage of the drying process begins when the sods are propped against one another in footings, small pyramids designed to catch the wind. This work is traditionally done by women and children. A few weeks later, the sods are reversed, or turnfooted. During June and July they are further turned and stacked into larger piles, called rickles and clamps, for more drying. By August the turf has dried to about 30 percent water content and acquired a watertight skin. It is now ready to be collected, transported home, and stacked for a final time. Once, the custom was to stack the winter's supply of turf against the gable end of the house to help insulate the home and shelter the turf from the rain. A well-built stack, however, is designed with the outside row of sods tilted downward so the water runs off; this repels the rain while allowing the wind to enter.

In some parts of the country, low-lying bogs too wet to cut with a slane are won by molding or kneading the turf into balls. Alternatively, the wet turf is spread on the surface of the bog, marked with grooves, and later cut with a spade and dried through the usual process. No matter how it is done, hand winning turf is time-consuming, hard work. For every ton burned, more than seven must be cut and spread to dry and shrink. Nevertheless, measured against today's fuel prices and energy needs, the clean-burning turf is an inexpensive fuel for country and city dweller alike. A pole, or perch (an old English land measure roughly seventeen feet long by ten feet wide), of bog in the Dublin Mountains can be leased for less than £10 a year. Thus, a family can cut its entire year's fuel supply for about twenty-four dollars.

With its sweet-smelling turf fire burning continuously day and night, the open hearth was at the heart of traditional Irish country life. Meals were prepared in cooking pots suspended from a wooden or iron fireplace crane. Clothes dried and people and ailing animals warmed themselves in front of the fire. Before the development of chimney flues, open turf fires were especially effective in heating homes. Turf smoke was no doubt a problem, despite the draft-regulating mechanism of the double doors found in most traditional homes, but the low furniture kept heads below the smoke. Moreover, the smoke and heat helped keep the thatch and roof timbers dry in a notoriously wet climate, which is one reason the ceilings of traditional Irish homes are open to the rafters. Wooden or stone seats were built next to the hearth, the fireside seat being the place of honor. Stories were told around the turf fire, and omens of the future were glimpsed in the way ashes fell and cooled. Once the fire went out, the soul supposedly went out of the people of the house.

The importance of turf as a fuel has increased with the industrial exploitation of the bog. In 1934, the

Gordon Johnson, Photo Researchers

Turf Development Board was formed and began cutting turf with large, combinelike machinery, primarily in the raised bogs of the midlands. During World War II, all coal was diverted to industry, and the entire country depended on turf for fuel. Huge piles were dumped in Phoenix Park for Dubliners to use, and the country's trains ran on turf. In 1946, a semistate body, Bord na Mona (Irish Turf Board), was organized to meet Ireland's energy needs. Although it is a commercial enterprise, the Bord receives capital loans from the government and is obliged to take national energy needs into account. Today, it controls 170,000 acres of bog, employs more than 5,500 people, and produces more than five million tons of fuel annually. Turf-fired power stations supply about a quarter of Ireland's electricity.

Bord na Mona has developed a highly mechanized system to harvest turf. Ninety percent is harvested in the form of milled peat. First, drainage ditches, four to five feet deep, are dug the length of the bog at intervals of forty-five feet. To let the water run off naturally, the bog is left for several years. When harvesting time arrives, eleven such parallel fields are worked as a single production unit. To shorten the drying time, a milling machine with a large, spiked drum slowly scrapes the surface of the bog to a depth of a half inch, leaving a layer of powdered turf. When this has dried it is then turned over by a machine known as a spoon harrow. In good weather, the turf may dry in less than a day, compared with many weeks for hand-cut sods.

When the turf is dry enough, a twin-bladed ridging machine scrapes it into a ridge in the center of each field. Each ridge is lifted by a mechanical harvester and carried by conveyor belt to the ridge in the adjoining field until all have been stockpiled in the central field. The stockpile is then covered with sheets of plastic. When turf is needed during the winter, the covering is removed, a temporary railway track is laid alongside the pile, and the turf is loaded for transport to the power station or briquette factory.

The entire milled-peat process takes three days, although rain at any time will cause a delay. In a typical season, mid-April to late September, twelve crops of turf can be won. Each cycle

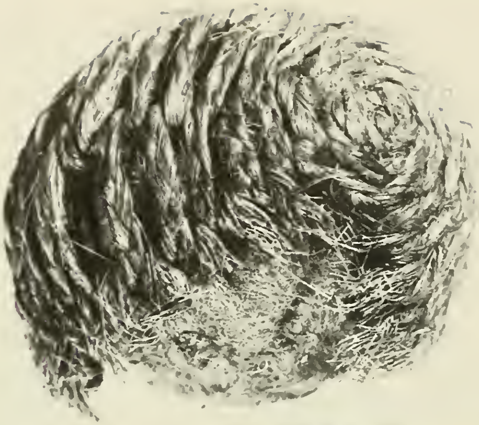
National Museum of Ireland

yields about six tons per acre. After the Soviet Union, Ireland is the world's largest producer of turf and such turf products as peat moss and turf briquettes. Owing to the great difference in land area, however, the gap in production between the two countries is large. It is said that more dried turf is blown off Soviet trains on their way to distribution centers than Ireland produces annually.

But the bog is more than a source of fuel. For centuries it has provided building materials and shelter. Until the turn of the century, Ireland's landless poor built houses of turf sods, much like those of the American prairie. The census of 1841, just before the Great Famine reduced Ireland's population by nearly a third, estimated that 40 percent of the country's 8.5 million people were living in one-room turf-and-mud cabins. During the famine itself, people seriously ill with infectious diseases, such as typhoid and diphtheria, were isolated in hastily erected, cone-shaped fever huts built of turf, with entrances "scarcely large enough for a dog to crawl through." Sweat houses, heated with turf fires and sealed with turf doors, were once commonly relied upon for cures. Usually, they were corbelled stone structures, but sometimes they were made entirely of turf sods or excavated into the side of a turf bank. Bog water was also believed to have medicinal properties.

Starting in the sixteenth century and lingering into the nineteenth, milch cows were taken to pasture on mountain bog each summer. Some family members, usually youths, went with the cattle and lived on the bog in temporary booley huts (from *buaile,* or "milking place") made of turf sods and boughs and roofed with long strips of closely grazed scraw, which had been peeled off the bog, rolled onto a stick, and carried like a carpet to the hut site. Some huts were circular in shape; others were square or rectangular. The latter had two opposite-facing doors through which the cows apparently passed one by one to be milked inside, a feature still found in many stone farmhouses in the west of Ireland. The booleys were often built in clusters, forming a temporary village where the inhabitants milked cows and sheep, cut turf, and made butter, which they stored in the bog. Seasonal nomadism greatly increased



*Left: This hair ball, found in a bog in County Limerick, was probably used in sporting events by the early Irish. Below: In the past, land was held in common and work in the bogs was cooperative. Today, although each family has a separate cutting face, several families, and generations, may share the work—and the relaxation.*

National Museum of Ireland

the capacity of small Irish farms. Fields near the house could be used for crops or hay from May until October, when the cattle were away on summer pasture. At the end of the summer, the booley houses could be dismantled and used for fuel and building materials.

Surprisingly, the bog is also a source of wood. Preserved tree limbs and trunks, the remains of the forests that once covered the country, are abundant in Irish bogs; the most common species are pine, oak, and yew. From the mid-seventeenth century, rich and poor alike were dependent on bog wood for furniture, roofing timbers, flooring, wainscoting, carts, boats, and all manner of domestic and farm equipment.

To locate the wood, Irishmen walked out on the bog in the early morning before the sun had dried the land. Wherever the dew or frost was thin or absent, the ground was probed with a bog augur, a long iron rod. Once the size and soundness of the timber had been determined, a trench was dug and the ebony-colored, iron-impregnated wood was laboriously raised with ropes and chains. Today Bord na Mona views bog wood as a major problem and spends the entire winter removing it from the bog so that the machinery will not be damaged when work begins in the summer. The wood must be dragged away or chewed up *in situ* by a machine known as a stump miller.

In the past, pine found in the bog was especially valuable. Resinous pine splints could be used in place of candles and torches. Pine wood was also

made into rope. Straight-grained pieces were cut into long strips and hammered into stringlike shreds that were then twisted together to form long strands. When the strands were sufficiently long, they were twisted together to form strong yet supple two- and three-ply rope. Bog-deal rope was used to cord wooden beds and chair seats, to lash roofing timbers, to tie down thatch roofs in windy areas, to secure hay and corn stacks, to make burden ropes, halters, tethers, traces, and straps for back baskets.

In addition to preserving wood, the bog is Ireland's most important source of archeological remains—a storehouse of tools, weapons, ornaments, and ceremonial objects. The finds include stone axheads and querns, flint arrowheads and microliths, brass dishes, wooden bowls, pottery, bronze sword blades and leather-covered shields, boats, plank roadways, house remains, and ancient field boundaries. Bord na Mona employees are instructed to watch for artifacts in the bog and are given a bonus when they make a find. In 1977 an eleventh-century bishop's crosier, said to be on a par with the Cross of Cong and the Shrine of Saint Patrick's Bell (masterpieces of twelfth-century Irish metalwork and design), was spotted glinting in the sun in Lemonaghan bog by a Bord na Mona worker. Earlier this year, a monastic find of great significance was made. Hidden in a bronze bowl beneath the bog at Derrynaflan, County Tipperary, were a richly decorated chalice, paten, paten stand, and wine strainer. According to Brendan O'Riordain of the National Museum of Ireland, the pieces date to the eighth or early ninth century. The Derrynaflan Paten, now at the British Museum to be cleaned, matches, in the richness and sophistication of its ornamentation and design, the Ardagh Chalice, an example of Early Christian metalwork that is one of Ireland's most important national treasures.

Colman Doyle, Source

The most interesting finds, however, are undoubtedly the bog people—bodies found in remarkable states of preservation. The earliest well-documented discovery of a bog person anywhere in the world comes from Ireland. In 1781, in a small bog on Drumkeragh Mountain, County Down, the body of a very small woman, assumed to have been Danish, was found lying on a layer of gravel under a thick bed of turf. The body, its head facing the east and its feet turned toward the west, was still clothed in the garments worn at death: a skirt made of skin, a finely woven and decorated cape, a veil of light fabric, and a woolen blanket. Since that first find, at least twenty more bodies have been recovered. In all cases it was the acid in the water, combined with low temperatures and the absence of oxygen, rather than any preservative in the turf itself, that tanned the skin and organs and so preserved them for centuries.

Less spectacular perhaps, but equally curious, are the numerous wood, cloth, and skin containers filled with "bog butter." As much as 100 pounds has been found in a single cache. There are many references from the seventeenth and eighteenth centuries to the Irish practice of burying butter in the bog to store and ripen it, thereby strengthening its flavor. Some folklorists, however, believe the practice predates the introduction of Christianity to Ireland in the fifth century and has a less utilitarian origin. According to E.E. Evans, past professor of geography at Queen's University, Belfast, butter was originally buried to appease the powers of evil and assure an abundant flow of milk from the cows in the pastures. Surviving folktales and stories are full of the magical properties of butter. In the west of Ireland lumps of butter were thrown into the lakes and springs through which the cattle were driven in order to restore the animals to health. In the last century, farmers took it to fairs and sold it as grease for cart wheels. When found today, the butter, which has the consistency and smell of ripe, crumbly cheese, is supposed to be sent to the National Museum in Dublin, along with other archeological finds.

Bogs are also the repository of other information about Ireland's past—pollen, seeds, and insects. From these, botanists, geographers, and zoologists have been able to construct a chronological sequence of Ireland's landscapes and fauna. This sequence has helped explain the origin of the bogs.

According to geographers such as A.R. Orme of the University of California at Los Angeles, Ireland has two main types of bog—the raised bogs of the central lowlands, which make up one-third of the country's bogland, and the blanket bogs of the western seaboard and uplands. Bogs began developing in Ireland's vast central plain about 10,000 years ago, after an improvement in climate resulted in the retreat of glacial ice. The landscape left behind was strewn with glacial debris. The hollows among the debris had impermeable floors of silt and clay and were filled with meltwater. On high ground, a subarctic tundra vegetation of lichens, dwarf birch, and willow grew, followed by forests of pine, yew, and oak. Aquatic and marsh plants grew along the lake margins, trapping inflowing muds. Slowly a layer of poorly decayed marsh plants built up to the level of the water table. The surface was colonized by sedges and grasses. In some areas trees also invaded the surface, creating in time a layer of wood-peat in the bog. But more often the water table simply rose as the marshes themselves obstructed drainage. Layers of decaying plant debris accumulated, forcing the marsh up and beyond the lake margins. Surface plants found it more and more difficult to reach down and extract nutrients from the soil beneath the growing bog. Beginning about 7,000 years ago, they were eventually replaced by sphagnum moss, which could thrive on nothing more than surface rainwater. As the growth of sphagnum moss caused the entire bog surface and water table to rise into a dome of spongy vegetation, a raised bog was born. Today, raised bogs range in area from a few acres to many square miles and average twenty-five feet in depth.

In the uplands and along the west-

Right: On the raised bogs of the midlands, more than five million tons of fuel are harvested mechanically each year. Turf from these areas will be gone in forty years; the land will probably be reforested or used for grazing.*

Dan Budnick, Woodfin Camp and Associates ern seaboard, bogs developed much more recently, roughly 2,500 to 4,500 years ago. In many areas they grew on a previously wooded landscape that was disrupted by Neolithic and Bronze Age farmers. Bog can be seen overlying the stumps of trees and covering field walls, graves, and even homestead foundations. According to some scientists, human activity played the leading role in the development of bogs. After the forests were cleared, the land was cultivated to the point of exhaustion, and a hard layer of impermeable iron and clay minerals gradually accumulated. Above this layer, drainage was impeded and marsh plants began to invade the abandoned and now waterlogged farms. Blanket bog then grew in much the same way as the raised bog of the central lowlands, except that black bog rush replaced sphagnum moss as the dominant plant in the upper levels of the bog.

Other scientists ascribe greater importance to the role of climate, especially the wetter conditions of about 2,500 years ago. Today blanket bogs average six to eight feet in depth and are best developed in areas with more than 250 days and 50 inches of rain a year. After heavy rains, bog lying on steep slopes can become unstable. Bog flows, engulfing sheep, farmlands, and roads, have occurred in several parts of the country.

What role will the bog play in the landscape and culture of Ireland in the future? The remaining life of the raised bogs now being worked by Bord na Mona is estimated at forty years. When all the turf is gone the reclaimed land under the cut away bog will be added to the nation's resources. In scale and potential it ranks with Holland's polders and the reclamation of England's fenlands. The two most likely future uses of this land will be for reforestation and as grassland for cattle and sheep. The first bog to be cut by the Bord has already been planted in Sitka spruce and Contorta pine and now supports a thriving young forest. Vast areas of mountain bog, however, will remain to be cut by hand in the traditional way for generations to come. Parts of the bog have already been designated as wildlands and will be preserved intact for the future—a reminder of, and storehouse of information about, Ireland's past. □

# INTRODUCING THE NEW WORLD CAR

### ENGINEERING TEAMS FROM AMERICA AND OVERSEAS JOIN FORCES TO CREATE A NEW CAR WITH BETTER IDEAS FROM AROUND THE WORLD

Top engineers drawn from the worldwide resources of Ford Motor Company teamed up to create Escort.

They pooled their expertise ... compared, tested, evaluated, experimented—to come up with better ideas. The result: a high-mileage car built in America to take on the world. Escort will be made in America for American drivers ... with other models built and sold overseas.

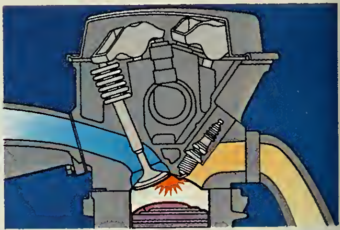
### HIGH MILEAGE THROUGH ADVANCED TECHNOLOGY

Escort's fuel efficiency comes from highly efficient new power teams, the use of special weight-efficient steel, refined aerodynamics and other new and better ideas, not less car. In fact, Escort has the room of a compact (based on EPA Volume Index).

| | EPA EST MPG* | EST HWY* |
|---|---|---|
| **ESCORT** | 30 | 44 |
| **EVEN HIGHER GAS MILEAGE THAN THESE LESS ROOMY SUBCOMPACTS.** | | |
| VW RABBIT (GAS) | 28 | 42 |
| TOYOTA COROLLA H/B | 28 | 39 |
| HONDA ACCORD | 27 | 36 |

*Applicable only to sedans without power steering or air conditioning. For comparison. Your mileage may differ depending on speed, distance, weather. Actual hwy mileage and Calif. ratings lower. Excludes diesels.

### ONE OF THE MOST POWER-EFFICIENT ENGINES AVAILABLE IN AMERICA



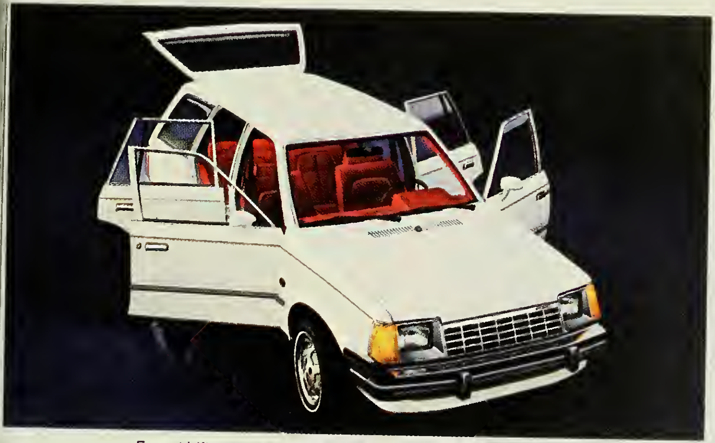
Escort's advanced-design compound valve hemispherical head (CVH) engine focuses the incoming combustion charge for power efficiency. Result: high mileage plus power for freeway driving.

And Escort has a new manual transmission with fuel-efficient fourth gear overdrive standard.

### FRONT-WHEEL DRIVE AND FOUR-WHEEL INDEPENDENT SUSPENSION

Escort has front-wheel drive ... four-wheel fully independent suspension ... rack-and-pinion steering ... stabilizer bar and new all-season steel-belted radials. And Escort makes use of a special steel—high-strength steel—along with other weight-efficient materials, for high mileage. Plus Escort offers a special all-new fast-cooling air-conditioning system.

FORD ESCORT



Escort Liftgate...4 doors and wagon room when you need it.

**DRIVE A WORLD CAR**

Whether you buy or lease, see your Ford Dealer now to order your Escort ...3-door Hatchback, 4-door Liftgate —ten choices in all—even a Squire wagon option. And remember to ask about Ford's Extended Service Plan.

**EVERY ESCORT HAS ALL THESE FEATURES *STANDARD***

- Front-wheel drive for traction.
- Fully independent four-wheel suspension for smooth road-holding.
- New-design compound valve hemispherical head (CVH) engine.
- Fully synchronized manual transmission with fuel-efficient fourth gear overdrive (automatic available).
- Rack-and-pinion steering.
- Bucket seats...scientifically contoured for comfort.
- Front stabilizer bar.
- All-season steel-belted radials.
- Lifeguard Design Safety Features.
- AM radio. (May be deleted for credit.)
- Electro-drive cooling fan.
- Pin slider disc brakes.
- Self-adjusting clutch.
- Front-wheel bearings need no periodic adjustment.
- Hideaway luggage compartment.
- Fold-down rear seat for extra cargo.
- Rectangular Halogen headlights.
- Flash-to-pass headlight control.
- Handy European-style wiper-washer fingertip control lever. And more.

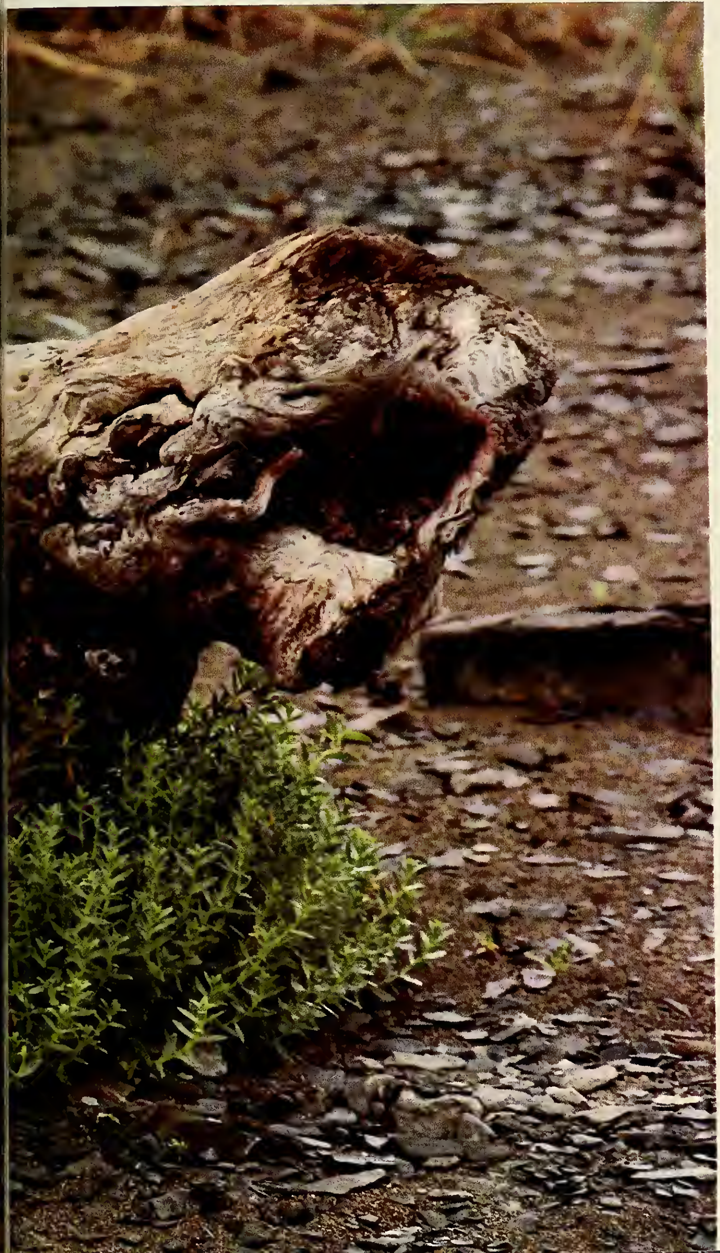
# Fox Hunting

*Whatever the type of prey, the red fox has a way of hunting it. But mostly, this canid hunts like a cat*

**by J. David Henry**



The fox stopped suddenly, thirty yards in front of me. Turning broadside on the deer run, it lifted its head and perked its ears. Then it slowly stalked off the trail, testing each foothold, careful not to break a twig or rustle a dry leaf. With its eyes fixed on small movements in the grass, the fox froze, then slowly coiled into a deep crouch. It waited, adjusted its feet, then lunged and catapulted over a low shrub. While in the air, it beat its plumelike tail several times to the left to turn its body slightly in that direction. It landed as gracefully as it had launched itself, its forepaws touching down where the grass had been moving moments before. It had tried to pin a mouse to the ground, but the prey had escaped into a burrow, one of many escape hatches that punctuate a mouse's home range. After a brief search, the fox returned to the deer run and continued along it, searching for other prey.

What I had just witnessed was by now a familiar sight to me. Every day for a month, I had been observing red foxes from dawn to dusk as they eked out their living in the northern forest. I was ten pounds lighter now and finally fit enough to keep up with these lithe carnivores. This autumn was my sixth year of studying free-ranging foxes, and during this time I had seen them hunt more than four hundred times. The locale for my study was Prince Albert National Park, a 1,500-square-mile wildlife sanctuary located in the boreal forest of northern Saskatchewan. The park, one of Canada's largest, preserves a northern landscape, an area that

*The long, thin canine tooth protruding from the mouth of this scratching red fox is an example of a catlike feature. By pressing its canines into the prey, the fox can easily disable its intended meal.*

blends sphagnum muskegs with chapellike aspen and spruce forests and serpentine jack pine eskers. One-third of this area is water—large oval lakes interconnected by a maze of meandering creeks and rivers. The forest that grows in this area is part of the taiga—the northern coniferous forest that stretches across the continent from Newfoundland to Alaska. The red foxes found within the park have been protected from hunting and trapping for more than fifty years and as a result have lost their shyness of humans. I found that with the right combination of physical endurance and assiduous patience, I could follow and observe these flame-colored predators as they raised their pups and made a living.

My research on red foxes is only one of numerous field studies on free-ranging carnivores completed during the past decade. Wolves, lions, hyenas, cougars, coyotes, and lynx have been studied, to mention only a few. When these studies are compared, certain interesting patterns emerge. An understanding of these patterns clarifies many aspects of the hunting behavior of the red fox.

The studies show that wild cats (felids) and dogs (canids) use dis-

*Similar to cats, the red fox has a glistening layer of connective tissue on the innermost sheath of its eyeballs. This tissue layer, or tapetum lucidum, reflects light back out of the eye.*

tinctly different hunting strategies: felids are generally built for stealth and bursts of speed; canids for endurance and moderate speed. Felids stalk close and make surprise attacks. Canids approach prey openly, outdistance it during a long run, and finally pull it down. Consequently, the hunting adaptations of felids are different from those of canids. Cats have evolved soft foot pads for stalking, a fine sense of balance for a motionless posture during the stalk, and hooked retractile claws and great coordination in the forelimbs for capturing prey. In order to make their killing bite effective, cats have evolved short muzzles, strong jaw muscles, and daggerlike canines. Dogs possess different morphological specifications. They have evolved adaptations for speed and endurance that help them in cursorial hunting. In addition, certain canids show highly developed social behaviors that allow packs of these hunters to overpower and kill large animals. Predation by members of the dog family generally is not based on stealth but on the detection, testing, and running down of weak or vulnerable animals. Dog packs also dispatch their prey in a manner different from cats. They kill by repeated biting, mainly at the prey's hind end. When the prey is weakened from these wounds, the pack eviscerates the animal and commences feeding.

There are interesting exceptions to these general evolutionary patterns. For example, the cheetah is a cat that hunts in a doglike manner. On the African savanna it approaches prey openly, pursues it in a fast run, and finally knocks it over. As a result, the cheetah shows both structural and behavioral convergent evolution with canids: it has evolved an elongated, doglike muzzle; long legs and a deep chest; blunt claws and thick, hard foot pads—all adaptations for speed and capturing prey on the run.

The lion is another exception since it practices communal hunting. George Schaller, who studied lions on the Serengeti for four years, calls it "the most sociable cat." In this aspect it resembles the wolf and African hunting dog. The adaptive value of communal hunting seems to be the same for all three predators, namely, more efficient searching for prey, plus the abilities to capture large prey and defend the carcass against other predators that may try to steal it.

The lion and the cheetah show that ecological selection pressures can cause a species to deviate from the hunting strategies typically shown by its taxonomic family and evolve hunting strategies similar to another taxonomic group. When I began studying the red fox, I wondered where in these patterns the fox would fit. Basically, I set out to find out what kind of predator the red fox is.

A highly successful species, the red

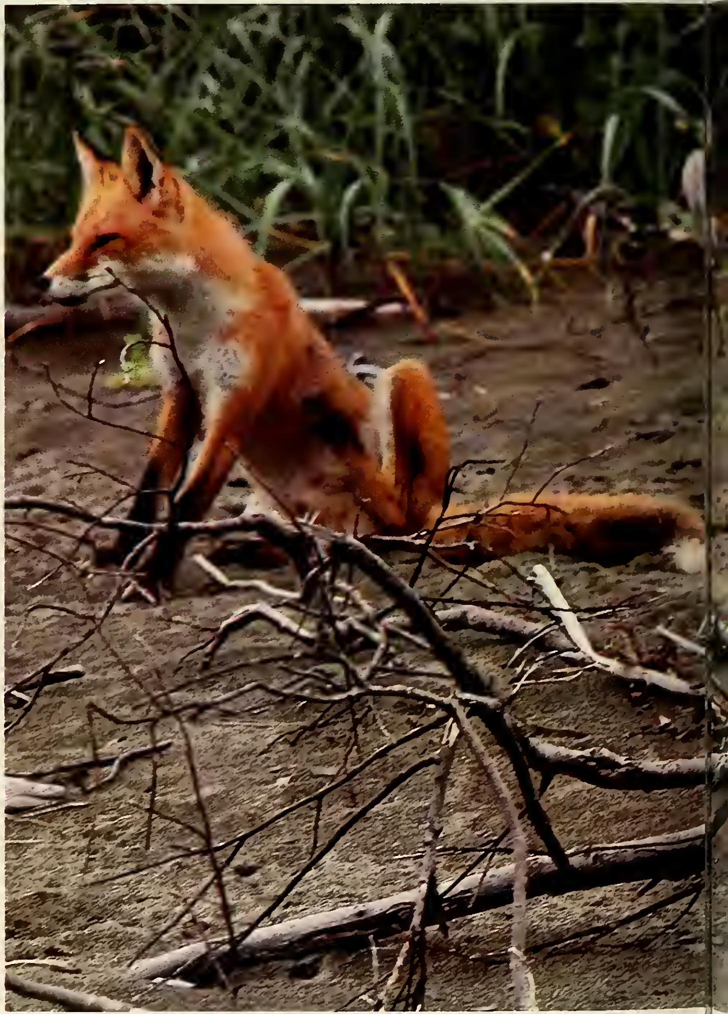
*Engaged in play, two pups become entangled while their mother remains alert and on guard. Pups, like kittens, hiss and spit at each other and at anything that approaches the den area.*

fox (*Vulpes vulpes*) is distributed throughout much of North America, Europe, Asia, and Africa, and has been introduced into Australia. Its food habits have been recorded in many locales. These studies consistently show that the red fox is not only a predator but also an opportunistic omnivore. It takes whatever food is most readily available, whether it be bird eggs, garbage, carrion, insects, or berries, but it usually relies on a few animal species as its real staples. Lagomorphs (rabbits and hares) and small rodents are generally the main items in the fox's diet.

The fox is not a miniature version of the wolf. Wolves are usually social pack hunters, while the red fox is a solitary predator. It hunts alone because of two intertwining conditions. First, the prey it catches are only large enough to feed one. Second, the best way to hunt these small prey is to stalk and use a surprise attack. Consequently, as the fox evolved into a specialized predator of small prey, it became progressively more solitary and like the smaller cats in its hunting behavior.

The fox's prey are not without their own defenses, which include alert vision, sensitive hearing, quick escape behaviors, camouflage coloration, stings, quills, and fetid sprays. In the ongoing evolutionary contest between predator and prey, both contestants are constantly evolving new adaptations to thwart the interests of the other side. In essence, predators and prey run an "arms race," with the prey developing new and improved mechanisms of defense and the predators in turn acquiring techniques to overcome these defenses. Over eons of time, this competition has led to the evolution of graceful, skilled predators and equally graceful, alert prey.

In the boreal forest the fox hunts animals that use four distinct sets of antipredator defenses. Consequently, the fox must use a different hunting strategy to capture insects, small bur-



rowing mammals, birds and tree squirrels, and snowshoe hares.

In a typical hunt for ground insects (crickets, grasshoppers, and beetles), and occasionally moths and flies, the fox travels along until it detects the prey in nearby grasses or on the forest floor, then casually walks over, bites down, and eats the insect. Usually it is as simple as that. Sometimes, however, the insect hops or flies away and the fox must search for it by poking its muzzle into shrubs or stamping one of its forefeet on the forest floor where it suspects the insect might be. After prodding the insect to move, the fox tries to locate it from small movements or rustling sounds. Interestingly, foxes were never observed using a foot-stamping action to crush an insect nor have I observed them using it in any other kind of hunt. Because these insects rarely show effective escape behaviors, the red fox exhibits a casual demeanor while hunting them. The fox's other prey offer more challenging contests.

The second strategy in the fox's hunting repertoire is used to capture voles, mice, ground squirrels, pocket gophers, and chipmunks—in short, any small mammal that escapes predation by fleeing into a burrow or under an object such as a rock or log. In the boreal forest, foxes usually hunt such prey while traveling along game trails, rabbit paths, hiking trails, or the edge of roadsides. The foxes hunt from these pathways apparently for two reasons. First, if the trail is wide enough to let in sunlight, dense vegetation grows adjacent to it and small mammals are frequently abundant. Second, foxes appear to use trails for quietness. The fox must approach the prey without being detected. If the fox makes a sound, such as cracking a dry twig, the prey will either crouch motionlessly, making detection difficult, or flee down a burrow or under a log.

The hunt begins with the fox walking down a trail. When it suspects a prey is adjacent to the path, the fox turns perpendicular to the trail, lifts its head and neck high, and stares intently. This elevated head posture is so characteristic of small burrowing mammal hunts that I termed it "head and neck in mousing position." A fox showing this head posture is almost always hunting.

If the fox cannot locate the prey, it may use a number of search tactics. For example, it may lower its head and sniff, trying to locate the prey from its scent. Or the fox may lift its head and rotate it, cocking it first one way and then another. These small head movements place the fox's ears at slightly different distances and angles from the sound. Henrik Österholm, a Scandinavian biologist, has shown that captive red foxes can locate a small rustling sound within one degree of its true location.

Alternatively, the fox may stalk to get closer to the prey. When stalking, the fox lowers its head and crouches down slightly. It moves slowly, carefully putting a forefoot down lightly on a spot and occasionally bringing it back up and choosing again. It tries to make as little noise as possible. To further reduce noise, the fox puts its hindfeet exactly where its forefeet had been.

After stalking for several yards, the fox assumes head in mousing position, and when it has located the prey, it crouches deeply and then lunges, arcing through the air. At the end of the lunge, the fox tries to pin the prey to the ground. Then it may dispatch the prey with several quick bites to the body or carry it off to a safe area where it plays with the prey like a cat with a mouse.

The fox's lunges are normally short (two to six feet), but they can be impressively long. I have observed red

foxes catapult fifteen feet through the air from a standing start and capture the prey. By way of comparison, the coyote, which is a third or more larger than the fox, has been observed to perform hunting lunges that are only eight feet or less in length. Foxes also show a preference for hunting the downhill side of trails. They may do this because by lunging downhill more area is placed within their reach. After observing several impressive downhill lunges, I made careful measurements and found that these foxes were airborne for a distance of up to twenty-five feet. Several adaptations, including proportionately long legs and a relatively light body weight, allow it to lunge these distances. The slender, long-legged silhouette of the red fox is a reflection of the adaptations that help to increase its hunting effectiveness.

When hunting birds and tree squirrels, red foxes rarely lunge; instead they stalk close to the prey and then charge in a crouched, dashing run. While I have observed more than a hundred instances of foxes hunting birds and squirrels, the foxes were rarely successful. In spring when these prey species are raising their young, they may be more vulnerable to fox predation, but on a year-round basis, birds and squirrels usually do not form a staple item in the fox's diet.

Foxes do not search for these arboreal prey but rather hunt them whenever they encounter them on the ground. When it spots a bird or squirrel, a fox immediately crouches so low that its belly almost touches the ground. Its neck is held horizontal, ears alert, and it remains motionless while staring intensely at its quarry. Then the fox "slink runs" at the prey, starting with a stalking pace, changing into a trot, and finally into a gallop. The fox maintains its low crouched posture throughout this charge. The last part of the slink run is a horizontal-thrust jump. It ends with the fox trying to catch the prey with a bite. The forepaw stab that foxes use to capture small burrowing mammals is not used to capture birds or squirrels.

A fox will sometimes hunt tree squirrels by stalking them in a curious stop-and-start manner. When stalking a squirrel in this way, the fox carefully watches the squirrel and tries to synchronize its movements with the prey's. Each time the squirrel faces away from the fox and begins to forage, the fox takes several quick steps in a deeply crouched posture, but freezes the instant the squirrel stops moving. The net effect is that the fox can mask its movements by synchronizing them to the movements of the squirrel. The fox appears tense and catlike when performing this synchronized stalking.

There is an interesting comparison between this type of stalking and the way a red fox stalks small burrowing mammals. The emphasis is different in each case. When stalking the small burrowing mammals, the fox puts its feet down slowly and is careful not to make any noise, but it moves its head about freely, alternately searching for a quiet route and then looking at the place where it suspects the prey is. On the other hand, during bird and squirrel hunts the fox may make little rustling sounds as its feet move across the ground, but it is always in a deeply crouched posture and its head and eyes are fixed on the prey as though tied to it by some invisible cord. These two stalking techniques appear designed to exploit different weaknesses in the antipredator defenses of different prey. In small mammal hunts the fox's stalking minimizes auditory cues that might alert the prey. During bird and squirrel hunts, stalking minimizes visual cues, while small noises are masked by the synchronization of the fox's movements with those of the prey.

Red foxes hunt rabbits and hares by stalking, followed by a "hell bent for leather" pursuit. This is the fourth hunting strategy that red foxes of the boreal forest show. In a typical hunt of a snowshoe hare, the fox crouches low to the ground and stalks slowly toward the prey while staring intently at it. Detecting the fox, the hare suddenly bolts and flees through thick cover while the fox follows in a bounding gallop. When it gets close to the hare, the fox attempts to bite it in the leg or rump. Frequently, at this point the hare will suddenly change direction. By zigzagging, it tries to

increase the distance between it and the fox. These actions may be repeated and the chase may cover a considerable amount of ground: the fox comes close; the hare zigzags and runs off in a new direction. Finally the hare either escapes into a briar patch dense enough so that the fox cannot follow or the predator gets a bite-hold on the prey. If the latter happens, the fox quickly pulls the hare off its feet and both collapse to the ground. The fox then quickly stands on its quarry, pins it to the ground with one or both forepaws, and bites it in the neck or head. Foxes are able to dispatch hares and rabbits quickly, perhaps because of the prey's slender neck and fenestrated skull.

There can be little doubt that the red fox is a bona fide member of the family Canidae. It shows all the diagnostic anatomical features that place it firmly in this taxonomic group. Evidence from the fossil record also confirms that the red fox is a canid. Yet many aspects of its hunting behavior are so catlike that I was struck by the possibility of convergent evolution between foxes and cats. Consequently, I conducted a search for features shared by red foxes and various small cats. This produced interesting results and has led to a new hypothesis concerning fox evolution.

Foxes and cats share numerous convergent features. For example, many fox species have long, catlike vibrissae on both the muzzle and the carpal (wrist) joints. These vibrissae are proportionately longer in these foxes than in other canid species. Field observations suggest that these whiskers function as tactile organs so that the muzzle vibrissae might help to guide the fox's capture and killing bites and the carpal vibrissae might assist the fox during stalking.

Foxes also exhibit proportionately long, thin canine teeth that resemble the long, daggerlike canine teeth commonly observed in cats. Many predators, once they have a small prey in their jaws, shake their head vigorously in order to immobilize and kill the prey. But red foxes and cats do not often show this behavior. Instead, they press their long canine teeth into the prey and keep exerting pressure until they damage the prey's central nervous system.

Red foxes also have catlike paws. For example, red foxes can flex and partially retract their front claws so that they are in fact semiretractile. Furthermore, the toe and foot pads of the fox are small and the rest of the foot is soft and covered with hair. I believe that these features not only reduce heat loss during winter but also function as adaptations for stalking by making the fox's feet more touch sensitive.

Convergent evolution between the fox and cat, however, is most striking in the anatomy of their eyes. Both animals exhibit a vertical-slit pupil and a highly developed tapetum lucidum. The tapetum lucidum is a glistening layer of connective tissue that has evolved on the innermost sheath of the eyeball. It reflects light back out of the eye and causes the eyes of foxes and cats to occasionally glow a luminous dull green even though no strong light is shining into them. This glistening membrane acts like a mirror behind the retina so that light passes over the retina twice instead of once. Using analogous photographic terms, the tapetum lucidum and vertical-slit pupil represent the evolution of a light-multiplying device with a shutter that can stop way down to accommodate bright sunlight.

Foxes also show many catlike features in their behaviors. For example, red foxes and gray foxes show a lateral threat display. A fox threatening with this display stands broadside, arches its back, erects its fur, and then charges broadside at the opponent in a stiff-legged gait. In addition, many of the fox's vocalizations are catlike. Like kittens, fox pups hiss and spit at each other and at disturbances. Adult red foxes exhibit a variety of high-pitched social calls that range from a short mewing cry to a loud, high-pitched alarm scream.

However, it is during hunting that the actions of a red fox most strongly resemble those of cats. For example, when hunting birds and squirrels, the fox—like a cat—stalks with its belly almost touching the ground or slink runs from cover to cover, crouching and waiting for its chance to ambush the prey.

What explanation is there for this convergent evolution between foxes and cats? Before a theory is offered, I must briefly examine the evolutionary history of these carnivores. Most paleontologists agree that canid and felid carnivores evolved from a common ancestral group, the miacids, approximately forty million years ago. These miacids were small weasellike or civetlike carnivores. They had an elongated body, a long tail, short limbs, and frequently, semiretractile claws. They were probably forest dwellers that preyed on insects and other small animals. Using this information, a theory can be advanced to explain the convergent evolution observed between foxes and cats. I suggest that foxes of the genus *Vulpes* differentiated early from the rest of Canidae and retained certain of their miacidlike characteristics, for example, a long tail, small foot pads, semiretractile claws, and long vibrissae. While the rest of the Canidae family evolved in a different direction, the foxes went on to show convergent evolution with Felidae and developed catlike hunting equipment in their morphologies and catlike hunting strategies in their behavioral repertoires. This convergent evolution is expressed to varying degrees among fox species and may be most strongly expressed in the red fox.

What ecological selection pressures would cause foxes to evolve in this way? As many food habit studies show, foxes in general and the red fox in particular hunt many of the same kinds of prey as small cats. To escape both fox and cat predation, their prey probably use similar antipredator devices. To capture their prey, foxes and cats have evolved a number of convergent features. Both have a well-developed tapetum lucidum and vertical-slit pupil for good nocturnal vision; long vibrissae; long, thin canines and the lack of head shaking for an effective killing bite; a fine sense of balance; soft, hair-covered feet; and quick reactions—all of which facilitate stalking and a surprise attack.

Consequently, the red fox, and perhaps other fox species, are as much exceptions to the canid taxonomic lineage as the cheetah and lion are to felid lineage. The red fox is a member of the Canidae, but because it hunts the same prey as small cats, the red fox has evolved to become a very catlike canid. □

*Rodents, rabbits, and hares are the staples of the red fox's diet in Prince Albert National Park, but foxes also eat a wide variety of other items, including birds, berries, insects, and carrion.*

# Welcoming the Wind

*Distinctive architectural forms tap desert winds for power and comfort*

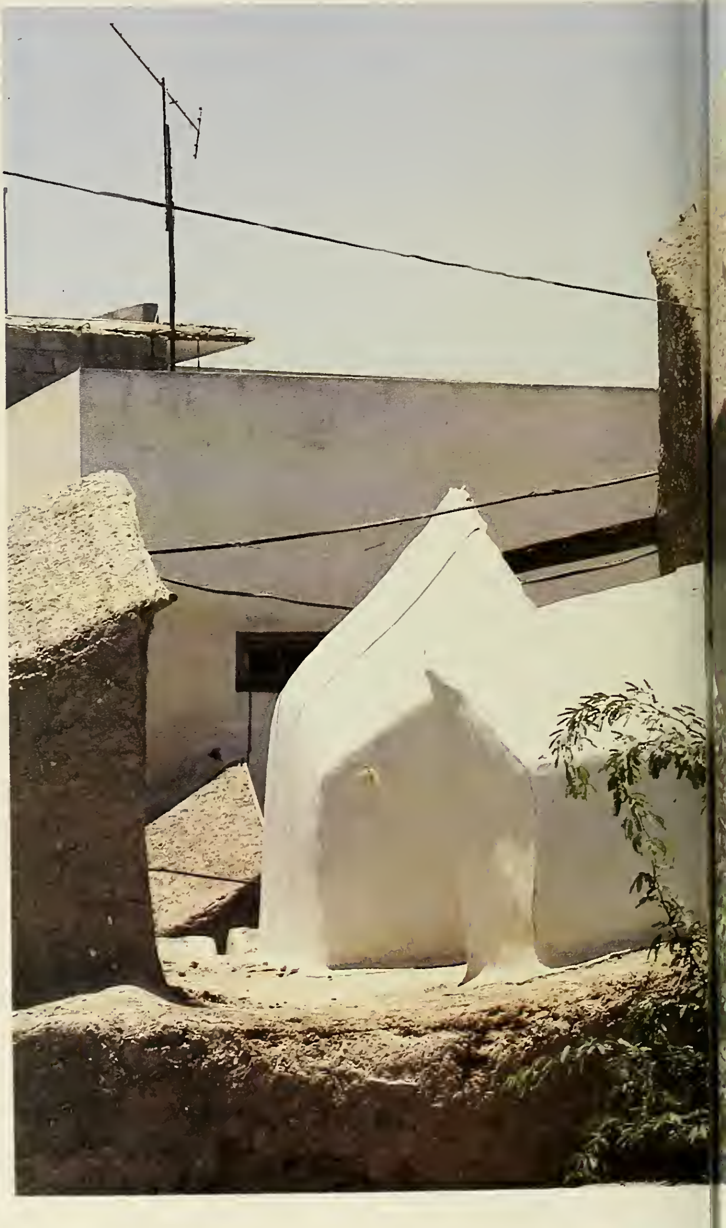
**by Jean-Louis Bourgeois**

From zephyr to tempest, the wind has many moods. Most architecture shelters us from it. But in some regions of the world, intriguing forms of traditional architecture welcome the wind.

The wind blows hard in western Afghanistan. Sweeping south from the Kyzyl-Kum steppes of inner Asia, a torrid gale known locally as the "wind of 120 days" and "the wind that kills cows" occurs almost daily from June through September. Often reaching 100 miles an hour, this wind blows hardest in Seistan, a dry, hot region that extends across Afghanistan's southwestern border into Iran.

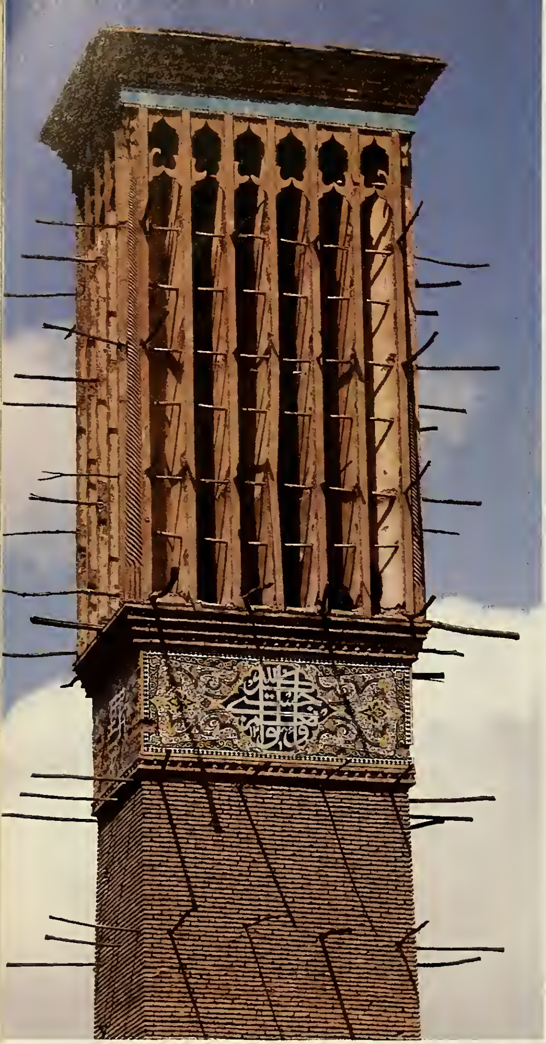
Seistanis turned their local meteorological scourge into a benefit. They were the first people to channel the wind's wild energy into work. During the ninth century, or before, Seistanis invented the windmill. They were perhaps inspired by horizontal, wind-driven prayer wheels, which whirled in Tibet and Mongolia at least as late as one hundred years ago. The sails of the initial Seistani mills almost certainly rotated horizontally like the millstone, thus bypassing the need for a gear to translate vertical into horizontal torque.

Not until the late twelfth century did windmills—with the familiar, vertically rotating sails—appear in Eu-



*The wind catcher is a simple but effective device that admits a refreshing breeze indoors. Its design and orientation are tailored to local meteorological conditions. In Tatta, a large town in the Sind region of southern Pakistan, wind catchers (shown here from the back), rise from roofs to swallow a southwest wind. Blowing from the sea, the cool wind, dried by its travel over the intervening desert, brings relief during the hot months of April through June.*

Carollee Pelos



Bruno Barbey, Magnum

*Above: In regions that lack a prevailing summer wind, many buildings are cooled by wind towers, which range from simple to grand. This one, in southeastern Iran, bristles with scaffolding poles, left in place to facilitate repair. The tall slots accept light breezes from any direction. At night, if the air is still, the tower acts as a ventilator. Air warmed in its mud-brick shaftways escapes upward, drawing cooler night air into the building through doorways and windows. Right: Horizontal windmills, such as these in western Afghanistan, recall the earliest windmills, invented more than one thousand years ago in the nearby region of Seistan. Rising from the domed mud-brick roof of the lower story, a mill's shaft bears sails of matted grass. The upper story is open at the back and on half of the side that faces the wind. The closed half of the front shields the returning sails. When the wind is fierce, additional mats are placed in the wind slot to keep the sails' speed down so that the millstones will not burn and blacken the flour.*

rope. And not until the late sixteenth century did they reach La Mancha, in central Spain. Probably because their whirling sails were new and strange to Cervantes, windmills outraged the gallant Don Quixote.

Early windmills prompted not only comical pique but also admiration and even wonder. Of Seistan, "the land of wind and sand," a tenth-century chronicler writes, "there is no place on earth where people make more use of the wind." A thirteenth-century commentator even compares the Seistanis' power over the wind to that of the early wind-master Solomon, the first person in legend to travel—with his entire court—on a flying carpet. Today, working horizontal windmills have almost disappeared, superseded by diesel-powered mills.

In the late nineteenth century, a local ruler in central Iran tried to import the horizontal windmill. At considerable expense, he built a huge mill to raise water. But the mill never pumped a quart—local winds were far too light to turn its sails. This mismatch of regional wind and vernacular wind device is rare if not unique. The rule is an exquisite pairing, best shown in traditional structures using the wind, not for energy, but to cool.

The strength of a region's wind governs the form and size of openings both to receive the wind and to vent it. In and near Seistan a powerful wind blows from a single direction, and the area's wind scoops are small and, facing into the wind, look northwest. Small ventilators are needed only over kitchens. Upper Egypt's prevailing summer wind is mild, so ventilators—which help draw the breeze through a building—yawn at least as large as the quite large wind catchers. In fact, in the latter region, free-standing porches actually face away from the wind, their back walls pierced by relatively small openings. The flow of air over and around the porch creates a low-pressure area within that pulls air through the openings. The reverse orientation would not allow sufficient venting to prevent the air inside from going stale.

In Iran's central plateau and along the Persian Gulf, torrid temperatures and light breezes have inspired thermal ingenuity. Wind towers—tall to reduce the admission of dust—are topped by slender openings up to thirty-five feet high. The giant slots, connected to individual passages within the tower's shaft, function alternately as intake and outlet. Facing all four quarters, they can harvest the slightest, most fickle breeze. After sundown, should the wind die, the heat stored in the tower's mud bricks warms the air, which—being less dense than the cooler surrounding night air—rises. This creates a draft that pulls a refreshing night breeze through doorways and windows.

In southern Pakistan, in a portion of the Sind region's flat desert, a southwest wind blows from April through June. Dry, steady, and cool, it is a blessing, arriving with the area's most brutal heat, when the daily maximum temperature averages 105 degrees Fahrenheit. The wind is moderate, so wind openings are large and ventilators infrequent. In a typical village hundreds of wind catchers reach high into the sky like giant periscopes, to clear the "wind shadows" of neighboring rooflines. They all turn their backs to the winter wind, which blows from the opposite quarter and is not needed indoors in cool weather.

Like that of most indigenous architecture, the history of lower Sind's wind catchers is obscure. Local tradition states only that their use is "very old." Their first written Western notice seems to have been by an English traveler who, visiting the city of Hyderabad in 1815, observed that wind catchers occurred on every house "from the governor's palace to the lowest hovel."

Southwest of Hyderabad, the large town of Tatta boasts wind catchers on the great majority of its houses. Most consist of just three flat planes and an anchoring post. But there are interesting variants. Sometimes, wind catchers do not rise from the roof but are incorporated into a building's highest story. Many are double or quadruple, the east–west axis two or four times the north–south axis. In a few cases, the ratio can be as much as seven to one. Below this type extends a long, narrow "wind room" whose entire ceiling is a wind catcher.

An elegant, twenty-year-old house in Tatta boasts a wind room twenty-eight feet long. On its lee wall, four windows and two doors can be opened in any combination to regulate the flow of air into two bedrooms and through them out to an open court and its wide colonnade. In the colonnade's four walls are twenty-one doors with transoms. Eleven wind catchers and two ventilators cool the entire house. Kitchen and toilets—and their odors—are to the lee of all bedrooms.

All wind catchers have a metal grate to prevent entry into the house via the roof. Except for the very large ones above wind rooms, all also have trap doors. Propping these at different angles governs the amount of air admitted. In winter they are shut. In multistoried houses, a shaft conveys the breeze to rooms on lower floors.

Wind-catcher technology runs the gamut from traditional to industrial. In many wind catchers, a base of sun-dried mud brick supports a deflecting plane of wood, the whole sheathed with a layer of mud mixed with dung and straw. More modern ones have a base of kiln-dried bricks, a plaster sheath, and a deflecting plane of corrugated steel supported by a wooden frame. The most modern ones are entirely concrete.

Another type of traditional air conditioning is used from northern India through Iran. A suitable local bush is woven into a loose, thick mat or packed into a frame, placed outside a window or door, and continuously or repeatedly drenched with water. A breeze evaporating the water can easily cool a room 15 degrees. In Indian cities, a special electric fan may replace the breeze. The entire appliance, a clever wedding of traditional and modern technology, is called a "desert cooler."

Architecture to catch a cooling wind is very old. Ancient Egyptian houses featured triangular wind devices. At least 1,200 years ago wind scoops caught the sea breeze on buildings in Peru. As rising fuel costs make industrial air conditioning prohibitively expensive, age-old ingenuity may come to the rescue. Meteorologically appropriate areas of the world would do well to adopt specific wind devices—ecologically sound forms of air conditioning at once cheap, efficient, and often beautiful. ☐

*The typical rooftop wind catcher in Hyderabad, in southern Pakistan, is elegantly constructed of two supporting planes and a third, deflecting plane, set at an angle and anchored by a post. A trapdoor can be adjusted to reduce or cut off the flow of air to the rooms below.*

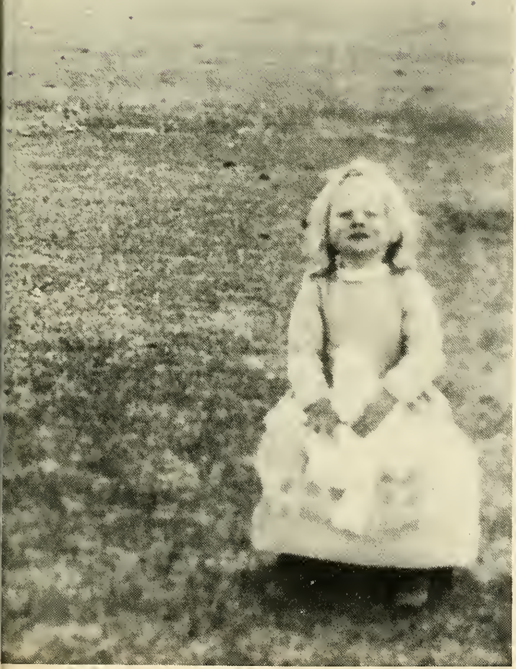
# No Fuel Like an Old Fuel

*Plains pioneers were quick to learn the virtues of "buffalo wood"*

**by Roger L. Welsch**



John Janovy's popular book, *Keith County Journal,* based on his observations as a field biologist in one of the sandhills counties in western Nebraska, opens with an essay on termites. This strikes plainsmen as peculiar, because termites eat wood, and there are no trees to speak of in Keith County. Still, termites have lived there for millenniums despite the lack of trees. Termites persist because they are adaptable, and in the case of Keith County, termites have come to live in and eat cow chips. Before that it was buffalo chips, and before that God only knows.

The Plains pioneers of the late nineteenth century found a land so sparsely populated with trees that guidebooks for various overland trails could instruct travelers to go westward "to the tree." My children have pointed to Colorado's mountains and asked me, "Which one is Pikes Peak, Dad?" but no child on the trails of the Great American Desert had to ask, "Which tree, Dad?" One great cottonwood that grew on the banks of Nebraska's Platte River gave its name to a town that clustered to its shade—Lone Tree. Eventually, that tree was hacked to pieces by travelers who, after two weeks' journey, apparently recognized that if their children were ever to grow up remembering what wood looked like, some had better be taken along. As novelist Wright Morris later wrote in his *Works of Love,* it appeared that forests, strictly speaking, were not going to be a part of the Nebraska landscape.

When white settlers first came to Indiana, the region was heavily forested—perhaps by as much as 60 percent—primarily with hardwoods such as oak, walnut, and hickory. Farther west, Illinois was roughly 40 to 50 percent forested; Iowa 18 percent. In the Plains state of Nebraska, trees covered only 3 percent of some 77,000 square miles. Forestation was concentrated along the eastern border, in the Missouri River valley. Some oak and walnut grew along eastern Plains streams, and pockets of cedar lay hidden in low, wet swales. On the islands of the Platte River, cottonwood, ash, and cedar found shelter from the annual, ravaging grass fires. But other than that, there were very few trees.

What trees there were, were grabbed up by the earliest settlers, who understandably wanted to build houses as God had meant houses to be built—of logs. But two or three houses per thousand square miles and the trees suitable for construction were used up. Younger trees were cut for railroad ties or for fuel. My guess is that by 1880 Nebraska was closer to 1 percent forested than 3 percent.

So the folk architects of the region turned for construction materials to sod, baled hay, skins, and used railroad ties. The houses could not be built of newly felled wood because there was none, nor of stone because there was none of that either, nor of brick because there was nothing with which to fire it. Even where there were log buildings on the Plains, there were no chimneys. Generations of women had cooked over open wood fires in brick and stone fireplaces and ovens. Now there was not only no more cod or cabbage or potatoes but there was also no fireplace. To be sure, the cast-iron cookstove was to the open fireplace what a microwave is to a cookstove, but the change, even if for the better, was disconcerting.

Even more traumatic was the change in the fuel used for cooking. Those same German, Norwegian, and Czech women who had for centuries scolded their men and children about wearing field shoes into the house, thus tracking bits of manure into the sanctified living quarters, were now reminding those husbands and children not to bother coming in unless they brought with them a good load of manure. Brought that manure into the kitchen, mind you. Like the termites, people had to adapt.

All manner of fuels were used throughout the last quarter of the nineteenth century and the first quarter of the twentieth on the northern Plains. I have collected recipes, for example, that specify the number of corn cobs to be added at intervals during the cooking process in a cast-iron stove. In "Little Old Sod Shanty on the Claim," the homesteading bachelor sings:

> When I left my Eastern home, a bachelor so gay,
> To try to win my way to wealth and fame,
> I little thought that I'd come down to burning
> twisted hay
> In my little old sod shanty on the claim.

Especially designed stoves compacted grass into drums to be fed slowly into the firebox flame. Children were put to work making "cats"—braids of grass tied in an overhand knot. When asked about the health of his wife, one settler replied that what with her carrying in cats and him carrying out ashes, he had not had much of a chance to inquire after her health. Sunflowers were grown for their woody stalks; people even tried to use sod as an uncured peat since it was, after all, primarily grass roots and humus. The remarkable effectiveness of sod, baled hay, log, and railroad-tie houses fortunately mitigated any extreme requirements for heating fuels, but the problem remained critical when it came to cooking fuels.

Earlier travelers on the Oregon and Mormon Trails had also had to deal with the problem. In the song "Crossing the Plains," an obvious veteran laments:

> There's not a log to make a seat along the river Platte,
> So when you eat, you've got to stand or sit down square
> and flat;
> It's fun to cook with buffalo wood, take some that's newly
> born,
> If I knew once what I know now, I'd a gone around the
> Horn!
>
> The ladies have the hardest time, that emigrate by land,
> For when they cook with buffalo wood, they often burn
> a hand
> And then they jaw their husbands round, get mad and
> spill the tea,
> Wish to the Lord they'd be taken down with a turn of
> the di-a-ree.

And the Mormons sang, in "Whoa, Ha, Buck and Jerry Boy!":

> There's a pretty little girl in the outfit ahead,
> Whoa, Ha, Buck and Jerry Boy!
> I wish she was by my side instead,
> Whoa, Ha, Buck and Jerry Boy!
> Look at her now with a pout on her lips
> As daintily with her finger tips
> She picks for the fire some buffalo chips,
> Whoa, Ha, Buck and Jerry Boy!

The process was simple enough. Bess Jacobsen wrote to me in a personal letter her memories of gathering cow chips on the Plains:

> I wish I had a dollar for every C.C. I "forked" into a wagon, unloaded, and stacked.... We started out with a wagon, old

*In the late 1890s, cow chips were dutifully collected by the sons of George Dew, a pioneer rancher in Cherry County, Nebraska.*

tub, and a couple of yards of rope, and a pitchfork. We would drive out on the range where the cattle had grazed. After the chips dried on the hot sand for a few days they were like dry wood. We would tie one end of the rope to the tub and the other end around our waist, fork up the chips, throw them in the tub, when full, empty them into the wagon until we had gathered a good load.

Take them home, stack them igloo fashion until the stack was almost as high as the house. That way they stayed dry all winter, as we used them from the bottom of the stack. Altho they burned very fast and it took a lot of them, they sure gave off a lot of heat. They didn't have an unpleasant odor, just about like burning grass, which they were.

The qualities of buffalo chips had been discovered in the mid-nineteenth century. The chips burn evenly, hotly, and cleanly, with little smoke and no odor. But it was the idea of the thing. Mari Sandoz evoked the times in her novel *Old Jules*:

> Different as these Kinkaiders were, they were united by two common bonds. They all wanted a railroad; still held meetings, consumed enormous amounts of chewing tobacco and time, and went home optimistic. The other was as most bonds are: a common need. Fuel. With no tree closer than the Niobrara River or the brush of the Snake, little money, and wretched roads over twenty to forty miles of sun-drenched or snow-glazed hills to the nearest railroad, wood and coal were out of the question. Cow chips were the solution. Most of the settlers had lost all the qualms that curse the fastidious long before they reached the hills. Barehanded they took up the battle, braving rattlesnakes, which upon acquaintance failed to live up to their reputation for aggressiveness. City women encased their still-white hands in huge gloves and, with a repugnance no extremity could completely erase, endured the first few weeks somehow. The music teacher wore gloves to the last.

Nebraska State Historical Society

It was also Sandoz who later noted that before long it was only the most fastidious woman who bothered to dust off her hands between stoking the stove and mixing the biscuit dough. Little wonder. Charlie O'Kieffe, in his *Western Story*, wrote as follows "for the edification of housewives who may never have cooked with buffalo chips":

> Stoke the stove, get out the flour sack, stoke the stove, wash your hands, mix the biscuit dough, stoke the stove, wash your hands, cut out the biscuits with the top of a baking powder can, stoke the stove, wash your hands, put the can of biscuits in the oven, keep on stoking the stove, until the biscuits are done.

Gathering cow chips or buffalo chips quickly became a way of life. Children gathered chips on their way to school and on the way home. The ardent suitor courted, not with a box of candy or a bouquet of posies, but with a bushel basket of chips, a sure key to the practical maiden's heart. It was reported that Nebraska girls could be identified by their overdeveloped right toes, which resulted from their hooking chips and turning them over to see if they were "done."

An old-timer told me that late one fall, when there was still not sufficient fuel gathered for the cruel Nebraska winter, he and his brother were confronted by their anxious father. The father thought that to increase the supply of chips perhaps the boys should gather some that were not fully "cured." "Boys," he asked, "are you getting them 'close' enough?" "Dad," the elder brother responded, "some of them are so close they're still warm."

Sylvia Grider, a Texas folklorist, has told me that the formula in that state is "flat and white, not round and brown."

Family and community contests were invented to encourage the understandably reluctant children at their task. In Enders, Nebraska, I was told by one homesteader's child that in his family, the child who brought in the biggest cow chip during the annual fall cow-chip harvest would get a silver dollar. After a dismal sequence of failures, he determined to win the contest by thinking well ahead. During the summer he gathered a formidable quantity of very fresh cow pies and fashioned a single gargantuan cow flop that would have put Paul Bunyan's Babe to shame. He rolled the seasoned cartwheel proudly home that fall, fully expecting to take the prize, only to find that the unappreciative family not only disqualified him from that year's contest but never trusted his entries from that point on and to this day will not buy life insurance from him.

As was the case with the multitude of miserable burdens inflicted on settlers of the northern Plains, chips too became the nucleus for a storm of esoteric jokes. I am not at all sure whether the survivors managed to laugh or the laughers managed to survive, but the close association is undeniable.

Euphemisms for the fuel were meant less to disguise the true meaning than to point quite explicitly to the repugnance of the situation. Chips were called cow wood (as in *bois de vache,* corrupted to "bushwa"), Hereford lump, Nebraska oak, Kansas coal, platters, and flop. Some observed that this was a wonderful land indeed where the cows cut the wood and the output of the family Bossie was measured less in gallons of milk or percentage of butterfat and increasingly in cords. Cooking with manure was said to eliminate the need for pepper. The Nebraska Federal Writers Project files contain a story from Grant Tibbles, who homesteaded south of North Platte, Nebraska, in 1888:

> Once I'd been three days in the canyons after fuel and my grub was gettin' low. I built a fire by moonlight out of cowchips and was sittin' there eatin' my supper when I dropped a piece of biscuit. I didn't want to waste it so I carefully picked it up and popped it into my mouth. Lordy, how I sputtered and spit. In the moonlight old cowchips is about the same color as biscuit.

A canon of esthetics developed, as in this account by James J. Lynch of Cherry County, in the archives of the Nebraska State Historical Society:

> The heavier the grass was where the load was dropped, the better the chip was for burning, and especially the seasons had much to do toward their value for burning: those in the fall where the cattle had access to eat the abundance of plums that grew along the creeks in those days, had much to do with their value. When you found a chip that was about half plum pits you had a very much desired burning article. Those chips burnt just like coal and generated a very hot fire and lasted far longer than the ordinary chip.

Joe Lansden, The Herald-Democrat, Beaver, Oklahoma

Joe Lansden, The Herald-Democrat, Beaver, Oklahoma

*A Great Plains community that celebrates its pioneer heritage is Beaver, Oklahoma, home of the annual World Championship Cow Chip Throw.*

Just as the song "Little Old Log Cabin in the Lane" could be adapted to Plains conditions by being changed to "Little Old Sod Shanty on the Claim," where there was no water the song "The Old Oaken Bucket" could be made appropriate to the new geography with heartfelt—if marginally literary—revisions:

A Ballad on Nebraska Fuel

How dear to the eyes in the land of Nebraska,
Where coal can't be bought and wood isn't found,
Where ozone is fresh as it is in Alaska,
Are the big piles of cowchips that lie on the ground—
The fire-kindling cowchips, the hash-cooking cowchips,
The corn-saving cowchips that's scattered around.
How ardent we seize it, with eyes that are glowing,
And say to ourselves that it cooks very well
And then when we're waiting and punching and blowing,
How rich are the fumes that arise to the smell!
The needful old cowchips, the odorous cowchips,
The hash-cooking cowchips so rich to the smell.
When we think of old woodland with hills that are "yaller,"
Where folks must be taught to toddle around,
We turn with disgust from its "aguery" pallor right back
Where both climate and cowchips are found—
The soggy old cowchips, the rich-scented cowchips,
The hash-cooking cowchips that out here are found.
When crops are a failure and stock is a-dyin',
And corn for our fuel cannot then be found;
When hauling our water, we're freezing and crying,
How welcome the cowchips that out here are found—
The genuine cowchips, the bonafide cowchips,
The pure-blooded cowchips that out here are found.
In this glorious country with water below us:
Where ozone in short takes the top off the ground;
Where hail storms benumb us and blizzards o'ercome us,
Are the soul-cheering cowchips that lie on the ground—
The time-honored cowchips, the homesteader's cowchips,
The fume-giving cowchips that lie on the ground.

(From the files of the Nebraska State Historical Society. Originally published in the September 13, 1934, *Hooker County Tribune* with the notation that this "melodious blank verse was found recently in the family Bible of the Hugh Elliot home northeast of Thedford and then thought to be a half century old. It bore the initials R. W. L.")

Prescott Webb devotes not a single line of his classic *The Great Plains* to cow chips. James Olson's *History of Nebraska* gives them a scant short paragraph. Frederick Jackson Turner writes of barbed wire and windmills but ignores the cow chip. It is, to be sure, a sensitive subject for a serious scholar, and yet without an appropriate consideration of the humble cow chip, one can understand neither the history nor the folklore of the Plains frontier.

# Ice Sheets and Ice Melts

*Sea level rises and falls as enormous blankets of frozen water wax and wane, changing the face of the land*

**by Cesare Emiliani**

There are floods and floods. Some, like the great floods of the Huangho (Yellow) River in China that killed almost a million people in 1882 and almost four million in 1931, are produced by unusually rapid snow melting or heavy rains. Others are produced by a sudden rise of sea level (by so-called tidal waves, which have nothing to do with tides), by submarine earthquakes, or by storms such as hurricanes. Examples of the latter are the Galveston flood of September 8, 1900, which killed 5,000 people, and the floods of August 1960 that hit Bangladesh and killed 10,000 people. Still other floods are the result of the collapse of natural or artificial dams or of landslides that end up in a lake, causing its water to overflow.

A spectacular example of the collapse of a natural dam was that of the ice tongue that dammed the fossil Lake Missoula during the last Ice Age about 14,000 years ago. The sudden draining of the lake resulted in the formation of the "channeled scablands" in southeastern Washington state, a landscape similar to that observed on Mars, which, apparently, was also produced by giant floods. An example of a landslide ending up in a lake is the one that filled up Lake Vajont, an artificial lake in northern Italy, on the night of October 9, 1963. Water flowing over the dam inundated the villages below and killed 1,800 people.

All these floods, destructive as they proved to be, were local. Although different giant floods, occurring at different times and in different places, may have been woven into the legend of a universal flood (for example, the deluge described in the Old Testament), a truly universal flood, affecting all coastal areas of the world at the same time can be produced in only two ways: by raising the floor of the ocean or by melting the ice on the land.

There have been times during the geologic past when large portions of the continents were covered with shallow seas. Geologists recognize two periods when flooding of the continents by the sea was particularly widespread: one during the late Ordovician, about 450 million years ago; the other during the late Cretaceous, about 80 million years ago. The late Ordovician marine invasion (or transgression, as geologists call it) was the largest flood of all. In the United States, only present-day Minnesota and Wisconsin, western Montana and northern Idaho, and small areas in Colorado and the Southwest, remained above water. All the rest was flooded. In late Cretaceous time, much of the West and the southern states were below water. These great transgressions resulted from global changes in the topography of the deep-ocean floor, most likely from the development of global submarine ridge systems. The system that broke up the supercontinent of Pangaea 180 million years ago is still active today. The Mid-Atlantic Ridge is part of it.

Submarine ridge systems take tens of millions of years to develop. Heated by the decay of radioactive elements and isotopes, rocks in the interior of the earth expand and overturn like a slow-boiling mass of porridge. A single overturn may take 200 million years. When hot rocks are brought up close to the earth's surface, heat does not escape continuously. Rather, the crust slowly swells up and then cracks, permitting seawater to penetrate it. As the water penetrates, heat is rapidly removed and the crust settles back until sufficient heat accumulates to start the process again.

The slow rise and more rapid sinking of the sea floor along the mid-ocean ridge system result in the sea slowly advancing onto the land and more rapidly withdrawing. Geologists studying marine deposits on land are familiar with these "sedimentary cycles." The sea may take several million years to advance on land and only a couple of million years, or less, to withdraw. Because vast areas of the continents are low lying, the sea can advance deep within a continent.

While marine transgressions and regressions produced by topographic changes on the ocean floor are very slow processes, much more rapid global movements of the sea can be produced by the waxing and waning of ice on land. During much of its geologic history, our planet has been free of ice. Only four major epochs of glaciations have occurred during the past billion years: in the late Precambrian period (about 600 million years ago); in the late Ordovician (about 450 million years ago); during the Carboniferous and the Permian periods (from 300 to 250 million years ago); and during the late Cenozoic era (from 15 million years ago to the present). The present ice epoch is still in progress, as shown by the huge ice sheets in Antarctica and Greenland.

Glaciation occurs when continental masses are at or near the poles. In Permian times, for instance, South Africa was located right on top of the South Pole and was surrounded by South America, Madagascar, India, Australia, and Antarctica. This great continental mass, called Pangaea, accumulated a huge ice sheet that grew and shrank in size many times during its 50 million years of existence. The repeated waxing and waning caused the sea to advance and retreat many times over low-lying continental areas, including much of the American in-

# New York on 45¢ a week

**No, we don't have a magic cure for inflation, but we do have something that can help you live better, save money, and put more excitement into your life.**

**It's New York Magazine (now including Cue) ... and you can have it delivered to your home for only 45¢ a week.**

NEW YORK
N

Nobody knows New York like *New York* Magazine. It's our reason for being: to bring you all the excitement and glamour, and to help you get more out of the world's most exhilarating city.

Let's take a short "tour" of *New York* and see how you can benefit from each information-packed issue.

**The Urban Strategist**
Need we do more to show you how *New York* can help you survive—and thrive—in the Big Apple than list a few recent articles: *Eating Smart: Great Dinners for Two for $50 ... Finding a Good Dry Cleaner ... What Every Stage Parent Should Know ...* and *Tenant Power*—your legal rights on everything from plumbing to co-oping to sleep-in lovers.

**New York's Writers**
*New York* has a bright style all its own and each one of *New York* Magazine's writers has a brilliant style to match. From Pete Hamill on *Spaldeen Summers* to Julie Baumgold on *Nixon's New Life in New York* ... John Ashbery's *The Glory of Picasso* ... Alan Rich on *Music: Kolodin vs. The Met—The Right Rake, The Wrong Muck* ... and Michael Kramer's *The National Interest: The Old Garth Magic.*

**People in the News**
There's no shortage of newsmakers in the city, and nobody covers them like *New York* in articles such as *The Best Doctors in New York ... The Men Who Own New York ... Arts and Crafts With Andy Warhol ... The Most Powerful Rabbis in New York ...* and *The Mysterious Mogul of Lincoln Center.*

**Theater and Movie Reviews**
John Simon, David Denby, and William Wolf are our aisle sitters for plays and films. Their lively, no-holds-barred reviews will help you decide which ones you should rush to see and which ones you should quietly forget.

**Fashion**
The newest styles, the latest look—you'll learn about them from John Duka as he previews the spring and fall fashions for men and women. And he'll keep you on top of the trends with such articles as *Flat Feet* and *Just Fur Fun.*

**Investigative Reporting**
There's no beat too offbeat for our writers, who dig deep for stories like *The Board of Ed Squanders Millions ... The Phone Company's Phantom Taxes ...* and *The Ambulance Chase.*

**Living in New York**
Nobody knows better what interests New Yorkers than *New York*. That's why we cover such subjects as *The Costs of Going Co-op: Can You Afford to Buy? ... Twelve Public Schools That Really Work ... Living in Tight Spaces ...* and *Seventeen Drugs to Keep you Happy, Healthy, and Sane in the Eighties.*

**Legal Aid**
*New York* zeros in on such knotty problems as *The Express Warranty—Protection When You Buy Anything ... Patients' and Passengers' Rights ... Auto Suggestions—How to Deal With Those Repair Shops ...* and *Your Rights in a Cab.*

**Best Bets**
You'll be a step ahead of the crowd on what's new, what's happening, and where to go ... like color-Xeroxed New York postcards that say "Wish you were here" ... Chinese grass whisk brooms ... lessons on how to start a play group ... and French biscuit boxes.

**Restaurants**
From Gael Greene's and Raymond Sokolov's trips to the heights of haute cuisine to the down-to-earth delights of "The Underground Gourmet," *New York* is a constant source of gastronomic ideas ... including such "must save" roundups as *An Almost Perfect Bistro ... Gifts From the Sea ... French Fare at Fair Prices ...* and *Country Dinners.*

**Food and Wine**
*New York* knows you don't always eat out, so we're there with a helping hand for at-home dining and entertaining with such timely tips as *Where to Buy Fresh Pasta ... Veal: The Great White Hoax ...* and *Specialty Meat Markets* (they'll do everything but light the oven) ... Alexis Bespaloff covers the world of wine from Auslese to Zinfandel, with an eye to finding "best buys."

**Cue Listings**
*New York* includes Cue, giving you a complete guide to entertainment, the arts, and dining every week. There are movie, theater, radio, and television listings, plus sections on music and dance, art, nightlife and other events around town.

**Potpourri**
Rounding out the New York style are reviews of books ... home furnishing news ... "Intelligencer" ... "Sales & Bargains" ... plus the unexpected. (That's definitely part of our style.)

We think once you've read *New York* you'll agree that there is no other magazine quite like it. And now you can have it delivered to your home each week at the basic rate of 29 issues for $12.98, only 45¢ a week. You save 80¢ a week off the $1.25 newsstand price.

*To order your subscription, mail the attached card today. (If card is missing, fill in and mail coupon below.)*

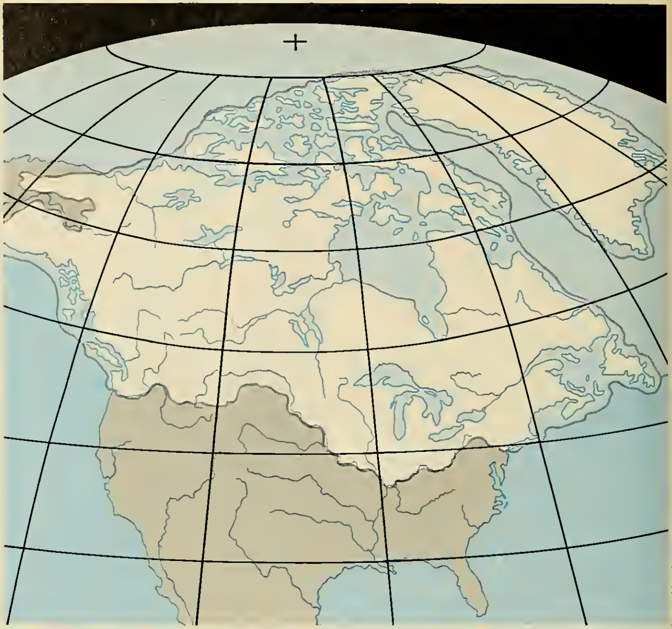
*During the last glacial maximum, some 20,000 years ago, sea level was about 300 feet lower than at present and a sheet of ice almost two miles thick covered vast areas of the North American continent.*

**The Laurentide Ice Sheet**



Joe LeMonnier

terior, which then had an equatorial position. Vast marshes formed in the interior where poor water circulation led to the preservation of decaying vegetable matter. With time, the layers of decaying matter became coal that now constitutes our largest energy resource.

As Africa and the other continental masses slowly drifted to their present positions at lower latitudes, Antarctica drifted to the South Pole. The present ice sheet began forming on Antarctica about 40 million years ago, but did not reach the shores of that continent until about 16 million years ago. There it has been sitting like a giant ice cube, chilling the entire ocean and keeping the temperature of the abyssal and deep water close to freezing. The abyssal fauna had to adapt to this new condition; those animals that couldn't, are not alive today. Meanwhile, the northern continents kept drifting northward until, today, they are jammed against each other around the North Pole.

About 4 million years ago, the Central American isthmus rose from the sea and blocked the exchange of water between the Pacific and Atlantic oceans. The result was a dramatic decrease in the amount of warm Atlantic water entering the Arctic and the appearance of ice in the surrounding lands. An ice sheet developed over Greenland at that time and has apparently been maintained there since. This further cooled the high northern latitudes and ice began appearing over both Canada and Scandinavia.

Ice forms under specific conditions of temperature, landscape morphology, and precipitation. A glacier is like a slow river: ice accumulates where snow falls and flows to areas where snow may not fall at all. The ice front is maintained when there is an equilibrium between the rate of ice flow and the rate of ice melting. This equilibrium is dictated by many different parameters, including the precessional, or wobbling, motions of the earth's axis that cause the seasonal amount of solar radiation falling at high latitudes to change with time. The result is a periodic advance and retreat of the ice. Ice retreated from Canada and Scandinavia between 14,000 and 6,000 years ago but in both areas small glaciers and icecaps have re-formed during the last 5,000 years.

The water to form ice on land can only come from the sea. The formation of ice on land, therefore, lowers sea level, and when it melts, sea level rises. If all the ice now present on earth were to melt, sea level would rise about 200 feet, enough to flood the Mississippi Valley all the way up to Memphis. During the last glacial maximum, about 20,000 years ago, sea level was about 300 feet below the present, and vast areas of the continental shelves of the world were dry land. The Bering Strait was also dry, permitting humans to walk from Siberia to Alaska and populate the New World.

The story of the advances and retreats of ice on the northern continents since the Central American isthmus was formed has been revealed by the study of deep-sea sediments. The shells of tiny animals and plants living in the surface water of the ocean accumulate in these sediments. If conditions were to change (if, for instance, temperature were to decrease because of an ice advance on the continents), the type of shells accumulating on the ocean floor and the isotopic composition of their carbonate material would also change. The study of these changes has shown that there have been about thirty periods of ice advance and retreat during the past three million years, roughly one every 100,000 years.

The process of ice growth is very slow, taking most of the 100,000 years' time from glaciation to glaciation. This is so because the growing ice cools the ocean, and the cooler, denser water sinks and is replaced by warmer water. The process of deglaciation, on the other hand, is very rapid: because ice meltwater has low salinity and density, it floats and can be rapidly heated by the sun. The melting of ice on a global scale, as during a period of deglaciation, is the most rapid way we know of to produce a global transgression, or a universal flood. The last one followed the last deglaciation and peaked between 12,000 and 11,000 years ago.

The amount of ice covering the North American continent during the last glacial maximum 20,000 years ago was truly phenomenal. Consisting of the huge Laurentide sheet to the east and the smaller Cordilleran sheet to the west, the total ice sheet was larger than that covering Antarctica today. Needless to say, environmental conditions on the continent then were vastly different from those of today. By analogy with contemporary Greenland and Antarctica, the thickness of the Laurentide ice sheet must have been some two miles. The greatest thickness was over Hudson Bay, but the ice was almost as thick as far south as the northern shores of the Great Lakes. Growth of the ice sheet through snowfall must have been very vigorous because of its relative proximity to the warm waters of the Gulf of Mexico and the western North Atlantic. Melting along the southern margin must have been equally vigorous in order to maintain equilibrium. Most of the Laurentide ice sheet drained down the Mississippi Valley, with the Missouri, Mississippi, and Ohio rivers contributing to the lower Mississippi Valley vast amounts of the muddy water that emerged from under the ice sheet.

Because of its high density from the heavy load of fine sediment particles abraded by the ice from the bedrock, the ice meltwater was capable of carrying pebbles as large as a fist all the way down the Mississippi Valley to Louisiana. Transport of these coarse materials was enhanced by the drop in sea level, which caused the rivers to cut into their own beds and resulted in a steeper downriver gradient. Sediment transport must have been particularly great in the late spring and summer, following the seasonal melting of winter snow and ice, and flooding must have been common.

The fine sediment left on flood plains was picked up by the wind and strewn over vast portions of the midcontinent, forming the deposit known as loess. Windstorms were probably common during the glacial maximum because of the steep temperature gradient between the ice sheet to the north and the warm seawater to the south and southeast. In the west, great lakes draining adjacent mountain glaciers were formed. These lakes, covering large areas of Utah, Nevada, southern Oregon, and eastern California, are now dry. Only the Great Salt Lake in northwest Utah remains, a small remnant of the much larger Lake Bonneville of glacial times.

A mass of ice the size of even a small glacier acts like a viscous fluid. Molasses, for example, will pile up on a table top as long as you keep pouring it. But once you stop, the

mound that you may have managed to make in the middle of the table rapidly flattens as the molasses flows out and drips to the floor. The Laurentide ice, and the Cordilleran and Scandinavian ice sheets as well, behaved in a similar way after the last glacial maximum. What apparently happened is that the surface seawater in the northern North Atlantic froze, resembling the Arctic of today, and in the process substantially reduced the supply of moisture to the ice. The ice began thinning out and melting along its leading edge, but its surface remained large because the ice kept flowing outward. Twelve thousand years ago about 70 percent of the water locked up in the ice sheets had returned to the ocean, raising sea level approximately 200 feet, from about 300 to about 100 feet below the present level. The ice front, however, still lingered in southern Wisconsin.

After the ice thinned, it began to retreat, producing a rise in temperature. With the warming, the pack ice on the northern oceanic areas disappeared and the supply of moisture was increased. The residual ice sheets were by that time not only very thin but also topographically depressed. In fact, the great mass of ice that had previously existed over the northern continents had depressed the surface of the land by many hundreds of feet through its own weight. Renewed precipitation from the oceans tended to wash away the residual ice rather than rebuild it to its original dimensions of thickness and area. In the North American midcontinent, this glacial meltdown produced giant floods down the Mississippi Valley and into the Gulf of Mexico. Waning ice, however, lingered in both Canada and Scandinavia until about 7,000 years ago, after which the last residue disappeared and the surface of the ocean rose to its present level.

The 300-foot rise of sea level that occurred between 17,000 and 7,000 years ago brought about an encroachment of water on previously dry areas of the continental shelves of the world. Mastodons once roamed the shelf off eastern North America as far out as 125 miles. It is a safe guess that humans, too, inhabited the now drowned shelves of the world. As seawater began rising, humans and animals had to retreat. On steep shorelines, like those around the Mediterranean, displacement inland was minimal. But where the shelves are broad and the slope is gentle, as off the east coast of North America and around the Gulf of Mexico, displacement inland was widespread.

The ice did not melt at a uniform pace. Scientists from the universities of Rhode Island, Miami, and Cambridge, England, noticed that the fossil shells of marine protozoans in certain sediment layers in deep-sea cores from the Gulf of Mexico were greatly depleted in the heavy oxygen-18 isotope. This indicated that the surface seawater where the shells grew was also depleted. That could only have happened if huge floods of ice meltwater had suddenly invaded the Gulf of Mexico. Using radiocarbon dating, scientists at the University of Miami were able to establish that this event took place about 11,600 years ago.

How big was the flood? The isotopic data, together with hydrological and oceanographic considerations, indicate that it was very large indeed. Considering that the volume of the Laurentide ice sheet at its maximum was equivalent to about 900 cubic miles of water, that three-fourths of it drained into the ocean from the Mississippi Valley during deglaciation, and that deglaciation took about 10,000 years, it is possible to calculate that the average yearly discharge of ice meltwater was about 400 cubic miles. To this amount we must add whatever additional precipitation dropped on the Laurentide icecap and the Mississippi Valley below during each year. If we assume that it was essentially the same as today, 135 cubic miles of water must be added, bringing the total Mississippi discharge during deglaciation to about 500 cubic miles, or almost four times the modern rate.

This was the average yearly discharge between 17,000 and 7,000 years ago. We know, from direct observation, that during a so-called fifty-year flood (a flood so large that it occurs only once in fifty years) the Mississippi can discharge as much as three times its total yearly average, or about 400 cubic miles of water. Applying the same ratio to the period of deglaciation, we estimate that a giant flood may have carried as much as 1,600 cubic miles of water, bringing the yearly total for a flood year to 2,000 cubic miles of water. Worldwide, the corresponding rise of sea level would still be very small (about one inch per year) but if the Cordilleran and Scandinavian ice sheets

were melting at comparable rates, sea level rise could have easily been twice as much. On the gently sloping shelves of the world, the sea would have been seen to advance inland 300 feet in a single year or, more appropriately, in a single summer when the snow and ice of winter melt.

At the peak of the last glaciation, Florida was a dry, windswept plateau with such steppelike vegetation as grasses and bushes. Since sea level was 300 feet below the present, one could have walked from Miami over Biscayne Bay to Miami Beach or Key Biscayne, and from there offshore for a mile or two. Then there was a rather steep, rocky slope, and about 300 feet down, a stormy sea would have been seen pounding dead coral reefs. Florida is built largely of porous limestone rock. Because sea level was lower, the water table was also lower, and little water would have been seen on the surface of the peninsula. Rain was immediately absorbed by the ground and found its way to the deep-water table through cracks and fissures, some of which were enlarged to become broad caverns.

In west-central Florida, southeast of Sarasota, there is a circular pond with a diameter of about 260 feet, called Little Salt Spring, that its few visitors thought was a small, tranquil lake. In 1959, an amateur underwater archeologist discovered that the center of the pond had no bottom. Instead, there was a circular opening, some 65 feet across, that gave entrance to a huge underwater chamber. Subsequent explorations showed that the chamber was almost 200 feet deep, was shaped like an inverted funnel, and had a broad circular ledge about seventy-five feet below the opening. These explorations (by Carl Clausen, a prominent underwater archeologist associated with the University of Miami) eventually focused attention on Little Salt Spring.

At the beginning of deglaciation, 17,000 years ago, when sea level stood about 300 feet below the present, Little Salt Spring was a dry cavity about 150 miles from the coast. As ice melted, sea level rose and the water table rose too. When the bottom of the cavern became flooded, Little Salt Spring became an attractive watering hole for nomadic Indian tribes. Twelve thousand years ago, the water level was just below the ledge in the cavern.

Underwater excavations indicate that the ancient Indians used Little

The Rubáiyát of Omar Khayyám

This is a complete recording, delivered by Louis Zoul, of Edward Fitzgerald's 5th version, and is the cumulative effort of three men of genius.

It is followed by a few comments and comparisons, and also Pedro Calderon de la Barca's The Dream Called Life and Life is a Dream.

Lastly, beginning with Hamlet's soliloquy, there is some of Shakespear's best.

Among the kudos we've received, this came from a professor in Ethiopia: "It is beyond compare!" A Brooklyn lady wrote: "I play it over and over. It is my treasure." While from Canada a gentleman requested: "Because the record is such a beauty, send another one."

Salt Spring not only as a source of fresh water, still a rare commodity on the dry limestone plateau, but also as a natural trap for corralling game. A picket fence made of two-foot-long wooden stakes surrounds the opening to the cavern. The stakes may have been used to support branches and thus hide the opening. Game was chased down the steep slope of the basin into the dark water below. There was no possibility of escape. The Indians, lowering themselves from the edge of the cave opening with ropes, would swing onto the ledge and from there capture the helpless animals.

The ledge has yielded bones of an extinct ground sloth, a rabbit, a wood ibis, an extinct bison, and a young mastodon. A giant tortoise shell surrounded by pieces of charcoal was found upside down. An artificially pointed wooden stake, still in place, had been driven through the animal's heart. The tortoise was then cooked on the spot. Only a few square feet of the ledge have been excavated so far, for the extremely dangerous work must be carried out under artificial light in about seventy-five feet of water.

The giant floods of about 12,000 years ago down the Mississippi Valley caused the water table to rise and chased humans off the ledge. Within 2,000 years the water level had risen to the opening at the bottom of the pond. Indians continued to live on the floor of the basin, to build fires and eat deer. Water continued to rise, and in another 1,500 years it reached the present margins of the pond. Because the water table was high, water was abundant on the Florida peninsula and Little Salt Spring was abandoned. Within 500 years, however, or about 8,000 years ago, the water level at Little Salt Spring began falling again and the Indians came back. The basin was once again the site of intense human activity.

The new wave of Indians lived in a village next to the slough, a swampy area adjacent to the pond, and buried their dead—often with branches of aromatic plants and objects and tools of wood, shell, and bone—in the soft muck of the slough and the basin. There are at least 1,000 burial sites at Little Salt Spring.

About 5,200 years ago, the water level begin to rise again, flooding the basin once more. The oxygen-poor environment of the muck in the bottom of the basin and the slough proved

an excellent preservative of the wooden tools. Hence, Little Salt Spring, once believed to be an insignificant pond among the thousands that dot the Florida plain, has turned out to be a major North American archeological find. Its story is intimately related to deglaciation on the northern continents and the accompanying sea-level change. We hope radiocarbon dating of the sediment covering the cavern ledge will help us pinpoint the rapidity of the rise of sea level that accompanied the great floods down the Mississippi Valley.

Along Bayshore Drive in Miami there is a 125,000-year-old rocky cliff in which the sea long ago carved deep notches. These notches are several feet above the highway. If we take into account the long-lasting sinking of the Florida Peninsula, it turns out that when the notches were formed, sea level was eighteen feet higher than it is today. The most likely explanation for the higher sea level is that some of the ice covering West Antarctica must have melted.

Scientists have estimated that if the ice of West Antarctica, a system of mountain ranges covered with thick glaciers, were to melt today, enough water would be provided to raise sea level about twenty feet. The last time the ice of Antarctica melted, 125,000 years ago, the low-lying coastal areas of the world, including all of south Florida, were flooded. At that time the world was at the peak of an interglacial age, the time between glaciations when world temperature is highest. Today, conditions are exactly the same: isotopic analysis of deep-sea cores shows that world temperature has risen as high as it was 125,000 years ago. But so far, West Antarctica has not melted.

Will it melt before renewed glaciation lowers sea level once more? To answer this question, scientists are now conducting a series of elaborate field observations in and around West Antarctica. The results to date have been rather contradictory. Some say that the West Antarctic ice sheet is unstable and in the process of collapsing; others say that this is not so. Whatever the case, the history of deglaciation of the Laurentide ice sheet and, in particular, its apparent collapse 11,600 years ago, as shown by the giant floods down the Mississippi Valley, may provide us with a glimpse of what could happen if the West Antarctic sheet goes. □

Buck Winter's Worst and really Enjoy It!
WARM PLAID LINED!
A Deluxe pair of Slacks!

Haband's
**Flannel Lined Winter Slacks**
only 21.95

**NOT A NECESSITY, BUT WORTHWHILE LUXURY!**

The outer fabric is tight woven windbreaking polyester and cotton poplin. A great all-weather quality cloth. And on the inside, they're completely lined, from waist to cuffs, with the softest, warmest, most comfortable all-cotton plaid flannel fabric that ever kept you warm and dry!

Permanent Press to hold their knife-like crease. Machine wash and dry, of course! *(We wouldn't ask you to worry about something like that!)*

In Navy or Tan, but you'll want both! Designed for bitter outdoor weather, there's no law that says you can't wear them indoors too, especially during a fuel crisis!

Order now! At Haband's inflation-fighting low price, combined with the wintry forecast and fuel uncertainty, we know these slacks won't be in stock for very long!

# Cloudy . . . with a Chance of Rain

## by Gerald Carson

The Rainmakers, by Clark C. Spence. *University of Nebraska Press; $15.95; 181 pp., illus.*

When the merciless sun boils down for weeks on end on the western states that early maps called the Great American Desert; when the corn leaves curl and sicken and even the willows and cottonwoods droop, then farmers and cattlemen scan the sky and anxiously watch the quote board for commodity futures on the Chicago Board of Trade.

Because the desire for rain is primitive and elemental, people, according to their nature and culture, pray, ring church bells, swear, grasp at folkloric theories about precipitation, and extend a credulous welcome to a class of entrepreneurs known as rainmakers. For years Clark C. Spence, a professor of history at the University of Illinois, has made it his scholarly avocation to collect material relating to this bizarre but neglected area of human gullibility. His sources are scattered newspaper and other ephemeral reports, manuscript collections in historical societies, the National Archives, and the U.S. Weather Bureau, and his book is the first full-length treatment of the subject.

The period covered takes notice of some ideas that have come down from antiquity, but extends for the most part from the early years of the nineteenth century down to the time of World War II, when lack of conclusive evidence discouraged the belief in the possibility of forced precipitation. Yet for a century and a half, mystics, spiritualists, flat-earth believers, Bible-text searchers who found in Leviticus 26:4 that they would receive "rain in due season," and outright opportunists all eagerly sought for some method of extracting at will the elusive moisture of the earth's atmosphere. Often they were men with magnetic personalities and an intuitive grasp of popular psychology, skilled in generating spectacular publicity.

A few individuals in good scientific repute advanced theories and claimed successes, men of the caliber of James Pollard Espy (1785–1860), an early meteorologist, and Joseph Henry (1797–1878), physicist and first secretary and director of the Smithsonian Institution, who instituted a system of weather prediction and made original contributions to the knowledge of climatology. Even the granger railroads, with an eye on freight traffic, offered farmers and townsmen suffering from the "drought mentality" financial support and solutions of their own; but they offered above all, hope. The majority of rain "professors" were simply smooth-tongued swindlers, members of the "plug hat" fraternity with a well-honed knowledge of the law of contracts, who employed techniques of persuasion that had been successful in peddling trees and nursery stock, patent gates, lightning rods, vanity books, upright pianos, and medical nostrums.

Professor Spence classifies the rainmakers on the basis of their speculative theories and their motivation. The confidence men were interested in money; the scientists wished to place the study of climatology upon a firmer foundation. Common to all was the belief that artificial means might be invoked to compel the atmosphere surrounding the earth to give up its content of moisture at a time and place chosen by the farmers of the Great Plains or the hydraulic miners of California. Various hypotheses for coaxing rain from reluctant clouds included the possibility of controlling the upward convection of warm, moist air; of jarring showers out of the sky by setting off explosions; of sowing rain clouds with a combi-

# QUARTZ

## Today begins a revolution.

## The Contax 139 Quartz: At last, 100% precision.

**World's first Quartz controlled camera.** The long awaited compact Contax 139 Quartz is here. A unique 35mm SLR, employing a consistently accurate quartz oscillator for unprecedented precision. A quartz accuracy working within the camera extends to all of its electronic accessories. Never before has a camera enjoyed this extreme level of exactness.

**Two independent SPD metering systems in one.** The metering systems use an ultra-sensitive prism sensor for normal exposures and an instantaneous response film plane sensor for flash photography.

**Exposure memory for critical metering.** Conveniently located Auto Exposure (AE) control locks exposure settings to get the best possible exposure in unusual lighting situations.

**Speed-of-light "pulse" viewfinder display.** Quartz accuracy readout uses 16 bright LED's for full-information on all modes of exposure including flash, the AE control and battery status. And the exposure preview automatically turns off after 10 seconds.

**Exclusive Auto Winder for easy control.** The functional design of this 2 fps winder allows for stable and comfortable handling. It also features a convenient vertical shutter release.

**Perfect flash exposures with the TLA-20 Auto Flash.** A through-the-lens Direct Flash Control system provides exact exposures at any aperture and total accuracy with any lens accessory, including bellows.

**A dramatically innovative Carl Zeiss lens.** A 7-element Planar T* 50mm f/1.7 lens is standard. And Zeiss, renowned for optical excellence, offers a full line of lenses including: the Vario-Sonnar T* f/3.5 40 to 80mm zoom; the S-Planar T* f/2.8 60mm macro; the "Olympia" Sonnar T* f/2.8 180mm telephoto, and more.

**And the technological revolution continues.** An LED flashing Quartz self-timer with reset capability; feather-touch electro/magnetic shutter release; infrared and radio remote control units as well as 200 other highly sophisticated accessories.

See this exciting revolution at your local Yashica/Contax dealer.

Harper's Weekly, *October 24, 1891*

nation of chemicals, among them liquid ammonia, brine, carbon dioxide, salt, sulfuric acid, and other exotic substances. Since the popular technical wonder of the nineteenth century was electricity, many inventors and theorists attempted to influence the aquiferous cloud cover by taking electricity out of the atmosphere—or putting it in.

Among the empirical notions that surfaced in the shadowy world of "pluviculture," as David Starr Jordan, naturalist, university president, and a skeptic, termed it, was the self-serving belief that plowing and new settlements would increase the rainfall and that steel rails and telegraph wires would also help. In years when rainfall was above normal, optimists declared that the climate was undergoing a permanent change in the direction of heavier precipitation. Down into the twentieth century it was held that rain follows battles, although it was an awkward fact that military campaigns are usually launched in good weather and that it was bound to rain sometime. So artillery fire produced rain: *post hoc, ergo propter hoc.*

Spence discusses in detail many persuasive rainmakers who emerged from obscurity and through studying almanacs and watching the barometer learned how to "make hay" in a dry year. The author conscientiously gives each his due. Two may be mentioned as specimens of the type: Allen Dorman, a Missourian who manufactured a laxative, produced artificial diamonds, published his own poetry, and claimed fifteen rainmaking successes for his Continental Rain-Making Company; and Charles M. Hatfield, self-styled "professor" and former sewing machine salesman, who made a good living out of his secret chemical method and a run of good luck until the drought-stricken thirties washed out the market for his services.

Somewhat higher on the social, or at least the economic, scale were Arthur Brisbane, an important editor and thinker in the William Randolph Hearst publishing empire, who recommended in 1910 that the U.S. government scatter liquid air or perhaps finely powdered lime in the atmosphere, and Charles W. Post, the multimillionaire cereal manufacturer (Postum, Post Toasties, and Grape Nuts). Post had interviewed many Civil War veterans; he believed in the concussion method and fought several "rain battles" in 1911 and 1912 on the Staked Plains of Texas and at Battle Creek, Michigan. Post had no interest in advancing scientific knowledge. He just wanted to prove he could impose his will upon the clouds. The cannonading at Battle Creek was followed by a real gully washer. But as the Weather Bureau pointed out, it rained that same day from the Great Lakes to the Pacific Ocean.

One important topic Spence does not develop is the remarkable absence of any consideration of the consequences of artificial rains. The effects upon vegetation, animal life, and soil erosion are simply ignored. To make this point compelling: How about mosquitos? The effects upon fish populations? And there is a legal thicket in here somewhere. The power to create rain would presumably include the power to withhold or divert it or to cause water to fall upon those who did not want it, such as spectators at athletic events, horse races, or agricultural fairs.

During the years the author has examined, the U.S. Weather Bureau held consistently that the scientific basis was lacking, that all rainmaking experiments were "entirely futile." Today, cloud seeding is being reappraised by the Department of the Interior as part of an enterprise known as Project Skywater. Questions remain touching upon the immensity of the cloud cover sheathing our planet and the effects of rainmaking on biotic communities. Spence has given us a pioneer work, as much about human credulity as climatology. A sequel would be welcome, bringing the story of artificial precipitation down to the decade of the 80s, including—along with the techniques—the legal problems and the environmental impact.

*Gerald Carson, author and social historian, is a frequent contributor to* Natural History *magazine.*

# Dietary Fiber and Animal Fat

*Differences in nutrition may explain regional patterns in some cancer*

**by Charles D. Gerson**

When we think of medical illness in the developing nations, we think of a long list of exotic and not so exotic diseases. In Europe and America, we are generally thought to be protected from many of the diseases on such a list by our improved sanitation, medical care, and nutrition. Recent reports in the medical literature suggest the opposite—that certain ailments are protected against in Africa and the East but are inadvertently fostered in the West. The main factors at work appear to be nutritional, and one of the anatomical systems most affected is the gastrointestinal tract.

The following story, which illustrates the above paradox, began in eastern Africa, specifically in Uganda. In the early 1960s, several British physicians noted that carcinoma of the colon, or cancer of the large intestine, was distinctly unusual in the Ugandan population. Most notable among those making this observation were Denis Burkitt, a surgeon interested in the incidence and epidemiology of disease in Africa, and Hugh Trowell, who served for many years as a consultant physician at Maherere University in Kampala, the Ugandan capital.

In addition, Burkitt and Trowell noticed that a number of other conditions that were commonplace in England were seldom seen in Uganda. These included diverticulosis of the colon, hemorrhoids, appendicitis, hiatal hernia (a weakness in the diaphragm muscle that separates the esophagus from the stomach), varicose veins, and a constipated bowel pattern. In contrast, in Great Britain and the United States, a gastroenterologist has daily contact with sufferers of these disorders, and in the United States, carcinoma of the colon is the most commonly occurring carcinoma, affecting some 100,000 persons annually.

Many millions of dollars are being spent treating patients with intestinal problems and millions more on cancer research. Burkitt and Trowell realized that Uganda presented an opportunity to deal with preventive measures, always cheaper by far. They were impressed with the effect of geography on disease patterns and felt there must be protective environmental factors at work in Africa. Burkitt was particularly enthusiastic about this idea and his focus was on what Africans are doing that Westerners are not.

There are several dietary differences between the two regions that are obvious to anyone who has ever lived in Africa. The diet there contains much more unprocessed and unrefined fiber, mostly in the form of vegetables. Accompanying this is an increased frequency of daily bowel movements associated with relative softening of the stool. Although not all gastroenterologists agree, many of the Western diseases mentioned above, including diverticulosis of the colon, hemorrhoids, varicosities, and hiatal hernia, could possibly be aggravated by increased pressure within the colon and abdomen, the kind of pressure that may build up in people who are constipated. On this basis, Burkitt formulated the hypothesis that a high fiber diet protected Ugandans from these illnesses by preventing constipation and its associated problems.

This was a provocative idea although subsequent research indicates that it was oversimplified and incomplete. However, like all provocative ideas, it served its main purpose by stimulating epidemiological and biochemical research, mainly in England and the United States. The goal has been to identify the protective elements in societies with a low disease incidence and the injurious elements where the same diseases are common. Whereas Burkitt highlighted the role of fiber as a possible protector, others have emphasized another nutritional difference, namely, that Westerners consume much more animal fat and protein than people in other cultures. In certain illnesses, fiber may be protective; in others, animal fat and protein may be injurious. Over the past decade, research has enabled us to better understand how diet and gastrointestinal disease interrelate.

Before discussing the effects of food fiber on intestinal function, we should understand what scientists and nutritionists mean when they talk about fiber. It is that part of vegetables, fruit, and cereals that resists digestion in the stomach and small intestine and is therefore unavailable as a nutrient source. From the small intestine, fiber enters the large intestine, or colon, where it is either metabolized by bacteria or excreted in the stool.

Most of the fiber of plant cells is found within the cell wall as cellulose, hemicellulose, pectin, and lignin. Part of fiber resides within the cell in the form of mucilages and gums, some of which are natural and some derived from food additives. Most of the substances in the cell wall are polysaccharides, or complex sugars. The main structure of the cell wall fiber is in the form of five-carbon sugars known as pentoses. These sugars have the ability to hold large amounts of water. Within the large intestine, this ability is translated into the creation of a bulk laxative effect and explains many of the attributes of fiber.

The gums and mucilages within the cell, plus the pectin of the cell wall, appear to have different structures and different effects. They consist not only of pentoses but also of hexoses, or six-carbon sugars. The presence of hexoses seems to mitigate against the water-holding ability of this part of dietary fiber. However, the gums, mucilages, and pectin, when given in pure form to humans, have their own particular action. They bind to other foods eaten with them and slow down the exit of food from the stomach to the small intestine. They also bind the bile salts, which are normally secreted by the liver to aid in the absorption of fat, including cholesterol. While these binding effects are not related to the controversy surrounding fiber and lower intestinal disease, there is some experimental evidence suggesting that they may be related to improved control of diabetes and a lowering of blood cholesterol levels.

A number of researchers have been studying the effect of food fiber on the colon. Most of this work has been done using bran, the best and easiest source of food fiber available. However, the societies with high fiber intake generally do not get their fiber from bran or wheat but from vegetables and fruit. In addition, bran appears to have a more dramatic effect on colonic function than other sources of fiber. Nevertheless, some generalizations can be made on the basis of the experiments that have been done with bran.

There are several ways of evaluating how dietary fiber with its bulk laxative effect may influence intestinal activ-

ity. The total amount of feces passed in twenty-four hours (the fecal volume) and the duration of time it takes for a nonabsorbed substance to pass from mouth to anus (the transit time) are two important measures. There is no doubt that both values are markedly different between Africans and the British or Americans.

In Africa, daily fecal volume is higher and transit time is lower. Lower transit time means a more rapid passage. There is generally an inverse relationship between fecal volume and transit time: the more rapid the transit time, the larger the fecal volume. Since the average African daily fiber intake exceeds three ounces and the average Western intake is less than one ounce, fiber is most likely responsible for the different measurements. This is where experiments with bran are applicable.

Bran was administered, usually in amounts of somewhat less than one ounce per day, to volunteer normal individuals in England by several gastrointestinal research units to see its effect. As expected, persons who ate the supplemental bran had a significant increase in their fecal volume and decrease in its transit time. In one study, concentrated fiber from cabbage, carrot, and apple caused similar but less marked changes. In another experiment, eating bran resulted in a reduction of internal pressure within the large intestine. This information supported the concept that fiber can alter colonic function. But the more interesting question is how fiber relates to colonic disease.

While the idea that fiber intake may be related to hemorrhoids, appendicitis, varicose veins, and hiatal hernia is interesting, it is not based on firm data. The concept that colon cancer may also be related to fiber is quite controversial and will be discussed later. The colonic disease that appears to be most clearly associated with fiber, or rather with a fiber deficient diet, is diverticulosis. A diverticulum of the colon is a small pouch, or pocket, that protrudes from the intestinal canal into the wall of the colon. In diverticulosis, a series of these pouches exists. The pouches alone cause no problem but they can become inflamed, a condition known as diverticulitis, and they can also occasionally cause a hemorrhage.

Fifty years ago diverticulosis was rarely diagnosed in Europe and the United States. Today it is a very common condition. Over 40 percent of people over the age of fifty and 60 percent of people over the age of seventy have diverticulosis. The tendency to develop these pouches increases with age. It also tends to occur in those with a constipated bowel pattern and increased pressure within the colonic canal. Presumably the pressure pushes the colonic wall outward in certain susceptible locations causing the formation of the pouches.

Since diverticulosis is a relatively modern disease associated with constipation and increased intracolonic pressure and since fiber intake appears to have been on the decline during the present century, it seems reasonable to surmise that a fiber-depleted diet may be at least one of the causes of diverticulosis. There is some experimental data that suggest this to be true. The incidence of diverticulosis in a group of British vegetarians with a daily diet of about one and a half ounces of fiber was compared with that in a group of normal age-matched controls who ate less than an ounce of fiber daily. All subjects were over forty-five years old. The vegetarians had a much lower overall percentage of diverticulosis—12 percent compared to 33 percent. Eating bran has also been shown to shorten intestinal transit time and reduce intracolonic pressure in patients with diverticulosis.

The cause of this disease used to be misunderstood, and the former medical custom was to treat patients with diverticulosis with a low fiber diet. The first person to see the way to a more rational approach was a British surgeon named Painter. He advocated the therapeutic use of bran in order to prevent painful attacks and forestall progression of the disease. He did this before all the current knowledge was available and should be credited with bucking the traditional approach.

Painter found that a large majority of his patients responded to a dietary treatment of about a half ounce of bran a day. While there was often an adjustment period when abdominal distension and gas were common, most patients had relief of abdominal pain and constipation. Now that we understand what bran does to colonic pressure and function, Painter's approach has gained general acceptance by other physicians.

Of all the diseases that originally attracted Burkitt's attention in Uganda, carcinoma of the colon is the most important. Because it is the most frequently diagnosed cancer in the United States, learning its cause commands a high priority. The infrequency of its diagnosis in East Africa led to questions about its worldwide distribution that have involved epidemiologists, biochemists, and bacteriologists.

One way to evaluate geographical influences on disease is to compare various possible causative factors with disease frequency in different populations. Carcinoma of the colon occurs with much lower frequency among the peoples of Africa, Asia, and South America than among the peoples of Canada, the United States, Great Britain, and northern Europe, with eastern Europeans somewhere in between. While fiber intake in African countries clearly exceeds that in Great Britain and the United States, there are many inconsistencies in the relationship between fiber intake and colon cancer in other countries so that the worldwide correlation is insignificant.

Studies of the relationship between chronic constipation and colon cancer also show no significant association and cast further doubt on the hypothesis that fiber ingestion protects against colon carcinoma. There is no experimental evidence in animal studies with carcinogens that fiber is protective. Detailed reports about colon cancer among Japanese also fail to establish dietary fiber as a possible preventive agent. In Japan, the disease has a very low incidence, but this rises markedly among Japanese who migrate to Hawaii, both among Issei (first generation) and more so among Nisei (subsequent generation) Japanese. This rise occurs without any significant decrease in fiber intake or increase in intestinal transit time.

All of this information suggests that a search be made for a causative component in the Western diet for colon cancer, and there is abundant evidence implicating animal fat as the culprit. In Africa, in addition to high fiber intake, the diet contains a relative paucity of animal fat and protein. In contrast, Western consumption of animal meat is substantial. The number of hamburgers consumed by Americans is fast approaching infinity. If one examines the correlation between colon cancer and animal fat and protein ingestion on an international basis, it is highly significant. An increase in beef consumption paralleled the increase in colon carcinoma among the Japanese in Hawaii.

Two English bacteriologists have provided bacteriological and biochemical evidence that has broadened our understanding of what eating animal fat may do to the large intestine. They collected a series of stool specimens from Uganda, India, Japan, the United States, and Great Britain and measured them for bacteria, cholesterol (derived from animal fat), and bile salts (secreted by the liver when fat is eaten). A number of differences were apparent between the countries with high and those with low colon cancer rates.

The stools of high-risk populations had higher anaerobic bacterial counts, more cholesterol, and more bile salts. The anaerobic bacteria are particularly adept at metabolizing cholesterol and bile salts and, accordingly, their metabolites were also present. Subsequent studies show that the bacteria in high risk populations have a number of other abilities, some of which could conceivably be applied to precarcinogens, converting them to carcinogens. Whether cholesterol or bile salts or their metabolites can act as a carcinogen or cocarcinogen is entirely speculative at this time.

However, additional evidence suggesting the animal fat–colon cancer connection has come from an epidemiologist and a biochemist working in New York City. They compared cholesterol and bile salt excretion among Japanese and Americans and confirmed the British findings. They have also compared excretory patterns in normal Americans, Americans with colon·cancer, and Americans with colonic polyps, considered to be a premalignant condition. Patients with cancer and those with polyps had cholesterol, bile salts, and their metabolites present in much higher amounts than did the controls.

Our understanding of disease causation progresses slowly and unevenly. We sometimes have to fill in one part of a puzzle while leaving certain voids elsewhere. The story presented here is not complete, but it provides an example of what can result from applying a sound research approach to epidemiological observations. Clearly, the improved nutrition of the Western world has some hazards and requires this type of critical evaluation.

*Charles D. Gerson, a gastroenterologist engaged in practice and research at Mount Sinai Hospital in New York City, has worked in West Africa.*

Jack Daniel's
WHISKEY

JACK DANIEL
SQUARE GLASS SET

Mr. Jack Daniel was the originator of the square bottle for his whiskey and always wanted to have a matching square glass. Well, here it is! This hefty square glass (each weighs 14 ounces) is the perfect companion to a bottle of Mr. Jack's finest. The inside is rounded to make drinking a pleasure and the original design is fired on for good looks and durability. My **$15.00** price for a set of 4 glasses (8 oz. capacity) includes postage.

**Send check, money order, or use American Express, Visa or Master Charge, including all numbers and signature.**

(Tennessee residents add 6% sales tax.) For a color catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to above address

# Additional Reading

**Bogs** (p. 48)

*The Bog People: Iron-Age Man Preserved* (Ithaca: Cornell University Press, 1975), by P.V. Glob, translated from the Danish by R. Bruce-Mitford, brings together information about many of the bodies found in bogs throughout northwestern Europe and contains many photographs of them. Glob concludes that many of the bog people may have been sacrificed as offerings to the gods or immolated for the good of the community; others were accident or murder victims. Written by botanists P.D. Moore and D.J. Bellamy, *Peatlands* (London: Elek Scientific Books, 1974) surveys the research being done throughout the world into aspects of mire and peat production. It discusses the ecology and hydrology of peat systems and the use of peat as an energy source, and includes an extensive bibliography. A classic in the field of Irish studies and a thorough review of Irish geography, T.W. Freeman's *Ireland, A General and Regional Geography* (4th ed. New York: Barnes & Noble, 1972), includes information on the different types of Irish bogs. *Irish Heritage* (Dundalk: Dundalgan Press, 1942), written and illustrated by historian-geographer E.E. Evans, devotes a comprehensive, profusely illustrated chapter to bogs. A useful summation of the area's ecology, replete with many photographs, maps, and diagrams, F.F. Darling's *Natural History in the Highlands and Islands* (London: Collins, 1967), contains a chapter on the formation and ecological cycles of bogs.

**Red Fox** (p. 60)

*The Wild Canids: Their Systematics, Behavioral Ecology, and Evolution* (New York: Van Nostrand Reinhold, 1975), edited by M.W. Fox with a foreword by K. Lorenz, is a thorough, illustrated, and indexed review of canid biology. Discussions of the red fox's behavioral ecology in Britain and America, its status in the United States, and its genetics and physiology are among the volume's several interesting articles on red foxes. M. Bekoff and M.C. Wells's "The Social Ecology of Coyotes" (*Scientific American,* April 1980, pp. 130–48) covers the way coyotes, a canid species closely related to the fox, interact with one another and with their environment. This ecological overview explores how the coyote's social organization is a reflection of food resources and the specific behavioral adaptations coyotes seem to make to different food supplies. How coyotes locate and kill prey, the effects of coyote predation, and how the species has adapted to pressures exerted by the environment are also discussed. "Comparisons of Canid and Felid Social Systems from an Evolutionary Perspective" by D.G. Kleiman and J.F. Eisenberg (*Animal Behaviour*, vol. 21, 1973, pp. 637–59), is an in-depth comparison of these two carnivore families. D.W. Macdonald's *Vulpina* (London: Collins, 1977), is an entertaining, accurate children's book about red foxes.

**Wind Architecture** (p. 70)

*Science and Civilisation in China,* volume 4, part II (Cambridge: Cambridge University Press, 1965), by J. Needham with the research assistance of Wang Ling, reviews in detail the origin of the windmill. In his architectural and socioeconomic study *Architecture for the Poor* (Chicago: Chicago University Press, 1973), Egyptian architect H. Fathy describes his approach to extensive reconstruction of housing for the Egyptian rural poor, using materials easily available, such as mud brick, sand, and straw. Fathy discusses forms of Egyptian architecture designed to benefit from climate, including wind catches and screens. "Bastakia Wind-Tower House" (*Architectural Review*, July 1975, pp. 51–53), is a report by P. Jackson and A. Coles on how industrialization threatens Bastakia, the old merchant quarter of Dubai, an area rich in traditional wind architecture. M.N. Bahadori analyzes the sophisticated Iranian wind tower in "Passive Cooling Systems in Iranian Architecture" (*Scientific American,* February 1978, pp. 144–54). Charts detail how different cooling systems use the natural environment to take advantage of Iran's wide range of temperatures. Drawing on examples of indigenous architecture, J.M. Fitch, in *American Building, The Environmental Forces That Shape It* (Boston: Houghton Mifflin Co., 1972), calls for a synthesis between advanced environmentalist theory and everyday architectural design and urges a link between modern architecture and climate.

**Ice Sheets** (p. 82)

For general background on the ice ages, readers should consult J. Imbrie and K.P. Imbrie's *Ice Ages* (Short Hills: Enslow Publishers, 1977), an explanation of the discovery and origin of the ice ages that includes an extensive discussion of temperature changes. R.F. Flint's classic *Glacial Geology and the Pleistocene Epoch* (New York: John Wiley and Sons, Inc., 1947) is a summary of the Pleistocene epoch meant for both geologists and the general reader interested in prehistory. Flint began *Glacial and Pleistocene Geology* (New York: John Wiley and Sons, Inc., 1957) as a revision of his 1947 text, but it evolved into a different book with more up-to-date treatment of some subjects, such as sea-floor stratigraphy and frozen-ground phenomena. C. Emiliani's "Climatic Record in Sediments," an article in the marine sediments section of the *Mc-Graw Hill Encyclopedia of Science and Technology* (vol. 8, New York: Mc-Graw Hill, Inc., 1971), analyzes the temperature record of certain undisturbed Caribbean and Pacific deep-sea cores. In "The Great Flood" (*Sea Frontiers*, September–October 1976, pp. 258–79), he writes about oxygen isotope analysis of sediments as a method of discovering past temperature oscillations, and about the world's largest ice sheet, much of which drained through the Mississippi Valley into the Gulf of Mexico.

UNIQUE, PRACTICAL SEWING PATTERNS. Waterbed sheets—customize yours for 50% retail. Duffle bags—any size. Fabric wallets. Visor organizer. 18 animals, applique/embroider. Brochure 25¢. Dewey Design, NH, Box 2824, Lincoln, NB 68502

FREE, EMBROIDERED CARDINAL PATCH. Two color, colorfast yarn, self-sticking, non-staining adhesive. Attach to clothing over and over again. Enclose $1.00 for shipping and Retail/Wholesale catalogue of 150 Nature and Science items. Museum Products, 3175 Gold Star Highway, Mystic, CT 06355

WALKING STICKS, CANES, Free color brochure. Marchele Co., Dept. NHK, 1123 Broadway, New York, NY 10010

## Music

FREE CATALOGUE. Musical instruments and kits—Harpsichords, Hammered and Appalachian dulcimers, lutes, guitars, etc. HDC, 4419 West Colfax, NH, Denver, CO 80204

## Photo/Optical

BINOCULAR SALES AND SERVICE. Repairing binoculars since 1923. Alignment performed on our U.S. Navy collimator. Free catalogue and our article "Know Your Binoculars," published in Audubon Magazine. Mirakel Optical Co., Inc., 331 Mansion St., West Coxsackie, NY 12192 (518) 731-2610

BIRDERS, NATURALISTS, PHOTOGRAPHERS. Highest quality 35mm slides from the collection of the Cornell University Laboratory of Ornithology. Birds, wildflowers, reptiles, amphibians. Free catalogue. Slides, 159 Sapsucker Woods Road, Ithaca, NY 14850

HUGE DISCOUNTS Nationally Advertised Brands. Binoculars, Spotting Scopes. Orders shipped prepaid. Free price list. Sandan Associates, Box 986, Delray Beach, FL 33444

IT'S ONLY NATURAL. South Cost Custom Color Laboratory produces the finest quality photographic printing possible from your color slides and negatives. Handprinted 8×10 to 20×24 color prints. Call or write for complete information. South Coast Custom Color Laboratory, 2011 State Street, Santa Barbara, CA 93101 (805) 963-5996

WILD-HEERBRUGG M5 Microscope with camera lucida, double iris diaphragm, and measuring reticle. (212) 898-1195

## Post Cards

NATURE POST CARDS—Close-up color photos of birds and animals. Beautiful & educational. $8.35 for 105, all different. (Not retailed to Illinois addresses. Wholesale rates available all states.) Nature Press, 628 E. 20th St., Alton, IL 62002

## Real Estate

FREE! Big Fall—Holiday Catalogue! Over 5,400 country properties described, pictured! Land, Farms, Homes, Businesses, Recreation, Retirement buys! Selected best thruout the U.S. Over 700 offices, 43 states All Across America! Yours Free from the World's Largest! Strout Realty, Inc., 60 E. 42nd Street, Dept. 5390, New York, NY 10017

FREE . . . 296-PAGE CATALOGUE. Describes and pictures over 2,700 farms, ranches, acreages, businesses and town and country homes from coast to coast. United Farm Agency, Inc., 612-U W. 47th St., Kansas City, MO 64112. Ph. Toll-Free: 1-800-821-2599; MO. Res. Ph. Toll-Free: 1-800-892-5785

GOVERNMENT LANDS . . . FROM $7.50/ACRE! Homesites, farming, vacationing, investment opportunities! "Government Land Buyer's Guide" plus nationwide listings—$2.00. Surplus Lands, Box 19107-RY, Washington, DC 20036

## Recordings

OLD TIME RADIO PROGRAMS on cassette tapes. Free catalogue. Cassette Library Center, P.O. Box 5331H, Baltimore, MD 21209

SOUNDS OF THE DEEP. A rare collector series of over twenty actual recordings of marine biological vocalisms from around the world. Only cassette of its kind available. $9.95. G. White, Box 19322, San Diego, CA 92119

## Resorts

MAINE: Remote fly-in XC ski lodge. Outstanding backcountry touring, beginner to expert. Warm comfortable cabins, excellent food, sauna, maximum 10 guests. Little Lyford, Brownville, ME 04414

ST. JOHN, VIRGIN ISLANDS. Two-bedroom beachfront house for rent. Attractively furnished spectacular view. From $400/wk in season, $325 out. Write: Seascape, Box 331, Medina, OH 44256

## Tours/Trips

ADVENTURES with WHALES and WILDLIFE. Observe whales in Baja lagoons and off Maui, Hawaii. Wildlife adventures in Tanzania, Kenya, Zambia and Zaire. Also Andes, Amazon, Galapagos, Nepal, India, Australia, New Zealand and Alaska. 1981 trip preview available. Adventures International, 4421-N Albert, Oakland, CA 94619

ADVENTUROUS SUBCONTINENT, Select Seasonal Tours: Grand India-Nepal Highlight, January Republic Parade. Geeta Tours, 1245 Jarvis, Chicago, IL 60626

AFRICAN EXPERIENCE: KENYA/TANZANIA 1981. Fully escorted. Forum Travel, 2437 Durant, Berkeley, CA 94704 (415) 843-8294

BORNEO, NEW GUINEA, Tribes/Wildlife—BOLIVIA, Llama trek/Jungle; from $4,000; Capers, Box 5489, Beverly Hills 90210

EGYPT 1981: March 4-14. Join small, hardy group interested in Natural Sciences (emphasizing Birds) and major sites of ancient and modern Egypt. Tour planned and led by leading American Ornithologist, Dr. Kenneth Horner. Accompanying lecturer Cairo University graduate in Egyptology. Explore 3 diverse ecosystems: Mediterranean littoral, Nile valley, Red Sea coast. Witness Eurasian bird migration across Sahara (150 species), 115 species native birds and over 100 species wintering. Moderately priced. Departs JFK. Schedule coincides with university Spring breaks. For Details write: "Egypt"—Beach Travel Service, Inc., Box 240, Virginia Beach, VA 23458

FOTO TOURS to world's most photogenic destinations with professional photographer Lisl Dennis, author of "How to Take Better Travel Photos". 1981 destinations: India, Egypt, China, and Tahiti. International Travel Bureau, Box NHM, 380 Madison Avenue, NYC 10017

FREE COLOR PEKING MAP—with the "Official Guidebook of China." Authorized by the Chinese. Everything to see and do. Complete, accurate, indispensible! $10.95 (includes shipping). Sino, Dept. 613, 745 5th Avenue, NYC 10151

FREE! Map/Birdlist—Chiricahua Mountains Area—plus illustrated brochure of our nature lovers' retreat—Cave Creek Ranch, Box F-1, Portal, AZ 85632

HIMALAYAN TRAVEL, INC. Trekking expeditions in the Everest and Annapurna areas of Nepal. Exotic cultures/spectacular mountain scenery. Box 481-NH, Greenwich, CT 06830. Toll free (800) 243-5330

LEG WALLET—For Men and Women. "Safe/Secure" Place for Cash, Credit Cards, Jewelry. Wear awake or asleep. (Beige or Black) $8.00 (2 for $13.00) Falcon, Inc., Box 331, Hialeah, FL 33011

LEGENDARY CULTURES, FASCINATING NATURE: Peru (Ecuador, Galapagos, Amazon), Mayaland (Guatemala, Yucatan, Honduras). Custom trips, reasonably priced. Expert leadership, Forum Travel, 2437 Durant, Berkeley, CA 94704 (415) 843-8294

MEXICAN & CENTRAL EXPEDITIONS by Wayne Hussing, 11120 Raphel Road, Upper Falls, MD 21156 (301) 592-7247—White water Rafting—Volcanic Climbs—Backpacking—Jungle Exploration—Overland Drives, Oct-July

NATURALIST GUIDED FIELD SEMINARS and tours, West Texas and Mexico. Rafting, hiking, backpacking, bus. University or Continuing Education credit as appropriate. Write Education Department, Chihuahuan Desert Research Institute, Box1334, Alpine, TX 79830

## RATE AND STYLE INFORMATION

$1.75 per word, 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# Celestial Events

### by Thomas D. Nicholson

**The Moon** A waning crescent in the morning sky during the first week, the moon becomes new on November 7, and the early crescent should appear in the evening sky by the 10th. First-quarter moon is on November 15, full moon on the 22nd and last-quarter on the 29th. The moon is new again on December 7, and first-quarter is on the 14th. Apogee moon (farthest from the earth) is on November 5 and December 2, perigee (nearest the earth) on November 20.

**Stars and Planets** The evening sky is almost devoid of bright planets this month. The morning sky is something else again. Venus, Jupiter, and Saturn are putting on quite a show, and Mercury joins them late in the month during an exceptionally good morning elongation. Look for the planets in the east at dawn on any morning. If you watch them regularly, you will see their continually changing relationships with the nearby bright stars Arcturus and Spica and with the crescent moon during the first week of November and December.

The sun is among the stars of Libra for most of November. It passes briefly through Scorpius and into Ophiucus before the end of the month. Mercury starts the month in Libra, moves backward (retrograde) into Virgo briefly at mid-month, and then back into Libra where it remains into December. Venus spends all but the last few days of November in Virgo, moving into Libra before December. Mars moves from Ophiucus into Sagittarius, Jupiter and Saturn are in Virgo, Uranus is in Libra, Neptune in Ophiucus, and Pluto in Bootes.

November 1: The star exceptionally close to the moon this morning is Regulus, in Leo. Observers in states along the Canadian border and in Alaska and Canada can see the moon cover Regulus (an occultation) from about 4:30 to 6:00 A.M., EST.

November 1–3: Watch the eastern sky each morning at dawn to see brilliant Venus move between Jupiter (the higher) and Saturn.

November 3: The Taurid meteor shower (about fifteen per hour) is at maximum.

November 3–4: Be sure to see the late crescent moon pass Jupiter, Saturn, and Venus in the dawn sky. The view on the morning of the 4th will be exceptional.

November 11: Mercury ends its retrograde movement and begins to shift east through the stars again.

November 16–17: The famous Leonid meteor shower reaches maximum.

November 19: Mercury is at its greatest distance to the sun's right, a very favorable elongation. Look for it any morning for another week, in the east after dawn, halfway between Venus and the horizon. Saturn and Jupiter (the brighter) are close together above Venus, and the star to Venus's right is Spica.

November 22: The full moon passes exceptionally close to Aldebaran, the bright star of Taurus, at about 5:00 P.M., EST, and separates slowly to the left of Aldebaran after they rise.

December 13–14: The Geminid meteor shower produces up to fifty per hour after midnight.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you face in the other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the evening sky at about 11 to 12 P.M. on November 1; 10 to 11 P.M. on November 15; 9 to 10 P.M. on November 30; and 8 to 9 P.M. on December 15. It shows only planets and moon phases above the horizon at those times.

# The Gamma Ray Mystery

*A possible source of this intense radiation has been identified*

**by Stephen P. Maran**

On about 100 occasions since mid-1967, space instruments have detected strong bursts of gamma rays. The sensitive apparatus currently available reveals that the bursts arrive near the earth about once every three weeks. Until last year, we had no definite information on where the radiation originates, but astronomers have now finally found one source of the mysterious bursts.

The pinpointing of a gamma ray burst was made possible when an exceptionally intense and rapid burst was recorded by nine different satellites and interplanetary space probes of the United States, the Soviet Union, and the Federal Republic of Germany. This event occurred on March 5, 1979.

Gamma rays are a very energetic form of light, with wavelengths shorter than X-rays. They are invisible to the naked eye. Indeed, cosmic gamma rays must be observed from high-altitude balloons or from space since they cannot penetrate all of the earth's atmosphere to reach the ground.

There is a general background of gamma rays that arrive at the earth from all directions at a steady rate, and there also are several known localized, nonbursting sources of the rays, such as the Crab Nebula. However, when a gamma ray burst occurs in a bright flash that often lasts only a few seconds, it briefly outshines all the other incoming gamma rays from the rest of the universe as seen from the earth.

Although not recognized at the time, the first known gamma ray burst was recorded by the U.S. satellites *Vela 4A* and *Vela 4B* on July 2, 1967. These and other satellites of the *Vela* series circle the earth in huge orbits, about 150,000 miles in diameter. From their distant vantage points, the *Velas*—each of which bears an array of sensors to measure gamma rays and other forms of radiation—can detect nuclear weapons blasts occurring above ground on the earth. Supposedly, they could even detect a nuclear bomb set off on the far side of the moon, although this capability has fortunately never had to be put to the test. Intended to monitor international compliance with the Limited Test Ban Treaty of 1963, the satellites provided unexpected dividends through the discovery and subsequent observations of the celestial gamma ray bursts.

In 1972, Ray Klebesadel, a physicist at the Los Alamos Scientific Laboratory in New Mexico, realized that some of the nonnuclear radiation recorded by *Vela* gamma ray detectors on July 2, 1967, and on later occasions was of a celestial nature. Ever since, astronomers have tried to locate the sources of the gamma ray bursts, and astrophysicists have speculated about the processes that generate them.

Progress was frustratingly slow, with an occasional bad lead, despite the enormous strengths of the bursts. According to a fairly conservative estimate made a few years ago, a typical gamma ray burst involves the release of as much energy in a few seconds as the earth receives from the sun during 20 million years. Luckily, the burst sources are much farther away than the sun.

The above estimate was based on the widely held assumption that the bursts come from within our own Milky Way galaxy. The more distant the source of an observed burst, of course, the greater the true energy of the burst at its point of release. Despite the assumption, however, no star or nebula in the Milky Way has been identified as a source of gamma ray bursts.

The basic problem in locating the bursts is this: We have, for practical purposes, two kinds of gamma ray detectors—omnidirectional (or nearly so) receivers and gamma ray telescopes. The omnidirectional receivers (such as the instruments aboard the *Velas*) respond—as their name implies—about equally well to gamma rays from any direction in space. Thus, they record nearly all the bursts bright enough to trigger their detectors. But by the same token, these receivers have no directional discrimination and hence cannot tell where the bursts

come from. Gamma ray telescopes *do* have directional discrimination, but they miss bursts that come from places where the telescopes are not looking. Since we do not know where the bursts come from or even when they will occur, the telescopes are not especially useful for studying them.

To locate the burst sources, astronomers have had to resort to analyzing the times at which each satellite records a given burst with an omnidirectional receiver. Since the satellites are at different locations, a burst traveling from its sources at the speed of light arrives at the various spacecraft at different times. Whichever satellite is closest to the source receives the burst first.

Given a few satellites, the general direction of a gamma ray burst source, defining a localized patch of the sky, can be determined. But it often turns out that two different sky patches are identified by this procedure; one is as likely to contain the source of a particular burst as is the other. Until the March 5, 1979, burst, the eighty-seventh observed since 1967, no sky area found in this manner was sufficiently small to warrant definitive observations with a large optical telescope, and no specific star or nebula was recognized as a gamma ray burst source.

By 1979, however, an "interplanetary gamma ray burst network" had been established, consisting of ten satellites and space probes. Of these, five were in orbit around the earth, one in orbit around Venus, and four were located in interplanetary space. The two network craft that were farthest apart were so widely separated that a ray of light would take more than ten minutes to travel from one vehicle to the other. The scientists responsible for operating the network included physicists at Los Alamos and at space research laboratories in Toulouse, Moscow, and Munich and at the Goddard Space Flight Center in Greenbelt, Maryland, and the University of Maryland in College Park.

In the interval since Klebesadel's discovery, theorists, who at first had proposed very disparate origins for the gamma ray bursts, had almost come to agree that the bursts must originate from neutron stars in the Milky Way; that is, from the tiny, extremely dense, and probably highly magnetized collapsed cores of ancient exploded stars—supernovae.

The most famous neutron star is the pulsar in the Crab Nebula, one of only two of the more than three hundred known neutron stars that can be detected in visible light (as opposed to radio waves or X-rays). The purported gamma ray burst-producing neutron stars are presumably likewise invisible and old enough so that (unlike the Crab pulsar) their surrounding nebulae, produced in the supernovae explosions, would have dissipated into space long ago. Further, not all neutron stars need be radio pulsars or X-ray sources. Thus, even if satellites had measured accurate positions for the gamma ray burst sources, astronomers would not have been very surprised if they found nothing at those locations.

It was thus with considerable interest that I learned last year that the strong burst of last March 5 had come from the direction of the Large Magellanic Cloud, a satellite galaxy of the Milky Way, about 150,000 light-years from the earth. If the March 5 burst (which as observed from the earth was a factor of ten stronger than any previously measured burst) had truly come from that galaxy, then it must have been produced by an event at least 100,000 times more energetic than the previously mentioned estimate of a typical gamma ray burst. For a fraction of a second, the burst must have been as powerful as a quasar.

I first learned this news in a phone conversation with Thomas Cline, a physicist colleague at the Goddard Space Flight Center who is a leader of the interplanetary network scientists. Remarkable as the report was, even more exciting information was yet to come. After a more detailed analysis of the data from the many satellites was completed, the search area was narrowed to a small box on the Large Magellanic Cloud. The box was occupied by a little remarked supernova remnant in that galaxy, known as N49.

Neutron stars form in supernova explosions and gamma ray bursts are thought to come from neutron stars. Thus you might expect astronomers to be pleased by the identification of the March 5, 1979, gamma ray burst with a supernova remnant that, we might reasonably infer, contains a neutron star. However, several different teams of scientists, including some experts on gamma ray bursts, have written papers challenging the discovery.

The dissenting scientists insist that the burst must have come, not from the Large Magellanic Cloud, but from a neutron star somewhere in the foreground, that is, near us in the Milky Way. They argue that it is only coincidence that the March 5 burst came from the direction of N49. And they point out that if so powerful a burst came from a star in the Large Magellanic Cloud, many such bursts should come from stars in our own much larger galaxy, and would appear even stronger to us. Yet, as measured from the earth, the March 5 burst was the most intense ever recorded. As a final point, they claim that a burst as energetic as the one in question must have been (if it came from 150,000 light-years away) simply cannot be generated.

Nevertheless, at least one theory has been proposed that apparently *can* explain the great energy of the gamma ray burst from the Large Magellanic Cloud. The radiation, it is asserted, came from the mutual annihilation of electrons and positrons, tiny particles of matter and antimatter, respectively. The spectrum of the gamma ray burst seems to support this theory. This technical debate seems to me, however, to turn on sophisticated concepts of physics while avoiding the real issue, which is, Do we accept the scientific method or merely pay it lip service?

For cogent astrophysical reasons, the prediction was made that neutron stars would prove to be the sources of the gamma ray bursts. Now we have found that a specific burst can be traced in the direction of a supernova remnant, the likely home of a neutron star. In my view the evidence compels us to consider this prediction at least provisionally confirmed even if we cannot explain the findings. It may make more sense to discard some speculations and calculations than to quarrel with the combined observations of nine separate satellites. Facts, often surprising, are surely more reliable than the products of scientists' imaginations.

UNFORGETTABLE
HONDURAS

Come discover a peaceful Caribbean retreat that's off the beaten tourist path. Honduras is a lush tropical country with gentle people, colorful customs, delectable local cuisine, and a proud heritage just waiting for the well-traveled adventurer. While Honduras also has bustling modern cities, there are still vast unspoiled regions where TV, high-rise hotels and fast food restaurants are unheard of.

From the peaceful Bay Islands, to the ancient Mayan Ruins at Copan, to the sleepy little outlying villages, you'll find Honduras a most extraordinary and enchanting adventure. Come explore the last unspoiled retreat. Come explore Honduras.

Tan sahsa

*"The International Airlines of Honduras." Serving all of Central America.*

**Tan Sahsa's El Camino Maya Vacation, 9 days, $307 plus air fare.** This adventure-filled vacation will take you from the bustling cities of San Pedro Sula and Tegucigalpa to the rolling mountainous countryside. You'll have plenty of time for browsing the marketplaces and taking optional excursions to ancient Mayan Ruins. Price includes hotels (per person double occupancy), taxes, transfers, some meals and a variety of sight-seeing tours.

For information on Honduras tour packages, call your travel agent or mail this coupon.

# Fossil Surgery

Like the rest of us, scientists at the American Museum of Natural History and elsewhere are fallible. Occasionally their mistakes go beyond the dense pages of an abstruse scientific journal and end up on display.

A year ago, curators at Pittsburgh's Carnegie Museum removed the head of their *Brontosaurus* skeleton, which after a long debate they had concluded belonged to another animal, and replaced it with a more delicate skull. The *Brontosaurus* in the American Museum, now subject to capital verdict, will also lose its head as soon as preparators can fix up a good copy of the new Carnegie skull.

*Brontosaurus* lost its head, but *Elasmosaurus*, a huge, long-necked marine reptile, suffered a worse fate. The first paleontologist to describe it placed its head on its tail, prompting a rival colleague to comment dryly that the new creature should have been named *Streptosaurus* ("twisted reptile").

The American Museum's brontosaurus had formed the basis for brontosaurus reconstructions elsewhere, including the Carnegie Museum's. Similarly, the first complete mammoth skeleton, which was mounted in Saint Petersburg, Russia, more than 200 years ago, was the granddaddy of subsequent reconstructions for nearly 150 years. For some unaccountable reason, the original skeleton was mounted with the tusks reversed, so they curved outward and backward, in flagrant contradiction to the arrangement we observe in elephants today. One hundred and fifty years later, Charles R. Knight, an American Museum artist, spotted the twisted tusks in a photograph and set the Russians straight.

Visitors to the Museum can observe the overactive imagination of several early Museum scientists in the fossil jaw of a great white shark, *Carcharodon megalodon*. This creature cruised the early Miocene seas, feeding on bony fishes and warmblooded marine mammals. The largest shark that ever lived, it looked almost exactly like the dreaded great white of today, only bigger.

With a length of forty-three feet and a weight of possibly nine tons, this particular fellow needed no help from Museum scientists to look impressive. Nevertheless, the paleontologists who reconstructed its jaw in 1909 made it nearly twice the size it should have been. They picked the biggest teeth they could find in the Museum's collection, even though a shark's teeth diminish greatly in size toward the back of the jaw. On top of that, they built plaster jawbones that were oversized even in proportion to the big teeth. The result was a maw of truly chimerical dimensions, six feet high and nine feet across. After completing their work, the six proud paleontologists stood inside the gaping jaw for a formal picture. Awed by their own creation, they estimated the creature must have been eighty feet long.

For some time the Museum has known the jaw is inaccurate. Now, John Maisey, a new curator in the Department of Vertebrate Paleontology, wants to do something about it. "The public," he says, "isn't going to like it, but the jaw will have to come down by a third at least. How could such an inaccurate reconstruction have been made if scientists were using live *Carcharodon* jaws for comparison? They let their enthusiasm run away with them."

Maisey, an expert on sharks, continued: "The fossil *Carcharodon* was a first-rate predator. Its descendant, the great white shark, is even warmblooded, which is essential for an active predator."

He turned over a palm-sized fossil tooth in his hand. "Its teeth were supremely adapted to biting and cutting. Scientists performed an experiment in which they shoved an aluminum-and-steel rod down a dead herring and fed it to an eight-foot bull shark. From the tooth dents in the rod they calculated its biting force at 40,000

**Poison-Dart Frogs and Other Friends**

Scientists from the Museum's Department of Herpetology will show live snakes, frogs, toads, lizards, and turtles on *Amphibian and Reptile Day*, Sunday, November 23, from noon to 4:00 P.M. in Gallery 3. They will also bring out mounted and preserved specimens from the collection and talk about the Museum's fieldwork and research in herpetology. *Amphibian and Reptile Day* is free for members, $3.00 for nonmembers.

**Tibet and China**

On the weekend of November 8 and 9, from 2:00 to 4:00 P.M. in the Auditorium, three films on the Himalayas will be shown. Included is C.S. Cutting's 1935 film *Beyond the Forbidden Frontier*, the first footage of life in Tibet. On November 15 and 16, three 1980 films on the People's Republic of China will look at life in three cities: X'ian, Suzhou, and Beijing (Peking). The films are free.

**Asia Live**

The People Center is presenting weekend programs that include dance, music, crafts, and traditional cooking from various regions of Asia: on November 1 and 2, Japan; November 8 and 9, the Himalayas; November 15 and 16, and 22 and 23, China; November 29 and 30, the Near East. All programs are free and run from 1:00 to 4:30 P.M.

**Mount St. Helens**

The Exhibit of the Month is a film that shows some of the recent eruptions of Mount St. Helens and other volcanoes. The film, which runs continuously in the Roosevelt Rotunda, discusses volcanoes and their causes.

**Time and the River**

An exhibition on the geology of the Grand Canyon and Bryce and Zion canyons is on display in Gallery 77. *Profiles of the Past: The Geology of Three Southwest Canyons* explores the geologic history of the Southwest as revealed by the canyons' rock walls. It includes photographs of the canyons, rock samples, geologic maps, and fossils.

**Dance and Music from the East**

Two programs of Asian dance and music will be presented in the Auditorium. On Sunday, November 2 at 2:00 P.M., Japanese dancer Saeko Ichinohe and her pounds per square inch. And *Carcharodon*, remember, was five times bigger than the bull shark.

"These sharks probably went through 10,000 teeth in a lifetime and swallowed many of their own teeth while feeding. They were always teething, which I imagine made them awfully cross."

Various people have posed for pictures inside the fossil jaw, including the staff of the present-day Vertebrate Paleontology Department. As publicity for the movie *Jaws*, Peter Benchley was filmed sitting inside the jaw with a lamp, table, and chair. Unfortunately, if the jaw is remodeled, it may no longer accommodate human beings.

Just as *Brontosaurus* was recently decapitated by the heartless progress of science, so, too, may *Carcharodon* suffer radical orthodontic alterations. Undoubtedly, as new discoveries are made, other reconstructed skeletons in the Museum's collections will undergo drastic surgery.

company will perform modern dances inspired by Japanese dance tradition. On Wednesday, November 5, at 7:00 P.M., the Chinese Music Ensemble of New York will present an evening of traditional Chinese music and some modern Chinese compositions. Beginning two hours before each performance, free tickets will be distributed on a first-come, first-served basis at the first floor Information Desk.

**Prizewinners**

The winning photographs of the 1980 Natural History Photographic Competition are on display in the Center Gallery.

**Scrutinizing Crowds**

The November Members' program will be a lecture by William H. Whyte on his ten-year study of urban spaces. Whyte, author of *The Social Life of Urban Spaces* and "Street Life" (*Natural History*, August 1980), will use slides and film to illustrate how people use New York's streets, plazas, and parks. This program is free for members, $3.50 for non-members, and will be presented in the Auditorium on Wednesday, November 12, at 7:30 P.M.

The World's Finest Miniature $20 Gold Piece

SOLID 22 KARAT GOLD ONLY $20.

*An Official Gold Issue of The Columbia Mint, Washington, D.C. in Solid 22 Karat Gold*

You have a rare opportunity to possess the world's first miniature $20.00 Gold Piece in solid 22 Karat Gold. This piece is minted in the same manner and contains the same fineness of pure gold (.900 fine) as the Saint-Gaudens $20.00 Gold Piece struck by the U.S. Mint in 1908. Each Gold Piece in pure .900 fine gold will be minted from hand-engraved dies capturing even the most delicate detail of the original Saint-Gaudens $20.00 Gold Piece. Individually minted to capture the full three-dimensional relief of this *the most beautiful of all U.S. coins.* Each brilliant pure gold miniature $20.00 Gold Piece is presented in a specially designed collector's case, accompanied by a serially numbered Certificate of Authenticity and a historical account of the Saint-Gaudens' gold coinage.

AVAILABLE FOR A LIMITED TIME!

This exquisitely minted solid 22 Karat Gold (.900 fine) Gold Piece is available exclusively from The Columbia Mint -one of America's private mints - Washington, D.C. The current special price for this Gold Piece is now $20. Due to the extreme fluctuations in the world market price of gold, this price can be guaranteed only until December 15, 1980. Therefore, you are urged to order yours now while the opportunity is before you.

SATISFACTION GUARANTEED

If for any reason you are not completely satisfied with your solid 22 Karat Gold (.900 fine) Gold Piece, you may return it within thirty (30) days for a full refund. There is a strict limit of five miniature Gold Pieces per order. However, you are reminded to act promptly to take advantage of the current special price of only $20. each as *this price can be guaranteed only until December 15, 1980.*

*Midwestern county fairs are a tribute to the traditions of American rural life*

**by Raymond Sokolov**

"As American as apple pie," we say, meaning that this apparently simple dessert is a symbol of the nation. But there is nothing at all simple about either the country or the pie. Needless to say, America has changed radically since early settlers brought their recipes for apple pie with them from Europe. And like all immigrants to these shores, apple pie took on a new nature in the New World. It became our preeminent national dish because in the isolated, primitive farmhouses of colonial America, apple pie was much more than a dessert. Ideally suited to the rugged climate and the low technology of the farms where most settlers lived, the apple pie was a basic means of survival: appetizer, entree, and dessert at winter meal after winter meal in the dawn of the Republic.

On the Ulster County, New York, farm he worked after the Revolution, Michel Guillaume Jean de Crèvecoeur harvested 100 apple trees for his own use, something he would not have done in his native France, and felt obliged to explain when he wrote about his life in a series of letters aimed at an urban European audience:

> Perhaps you may want to know what it is we want to do with so many apples. . . . In the fall of the year we dry great quantities, and this is one of the rural occupations which most amply reward us. Our method is this: we gather the best kind. The neighboring women are invited to spend the evening at our house. A basket of apples is given to each of them, which they peel, quarter, and core. . . . The quantity I have thus peeled is commonly twenty bushels, which gives me about three of dried ones.
>
> Next day a great stage is erected either in our grass plots or anywhere else where cattle can't come. Strong crotches are planted in the ground. Poles are horizontally fixed on these, and boards laid close together. . . . When the scaffold is thus erected, the apples are thinly spread over it. They are soon covered with all the bees and wasps and sucking flies of the neighborhood. This accelerates the operation of drying. Now and then they are turned. At night they are covered with blankets. If it is likely to rain, they are gathered and brought into the house. This is repeated until they are perfectly dry.

Processed in this way, Crèvecoeur's apples would last through the winter—a staple food source that required only an overnight soaking in warm water to be ready for the oven. Apples were at the very center of this pioneer farmer's diet. He wrote: "My wife's and my supper half of the year consists of apple-pie and milk."

Today, two centuries later in our history, no farmer sustains his family on apple pie suppers all winter long. And even if he did, a farmer is no longer typical of American life, for there are too few of them. But farmers are still the guardians of symbolic values and practices sacred to the nation's sense of itself. They are uniquely equipped to continue and preserve our traditions, particularly our food customs, in pristine form because almost without exception, American food customs arose in farmhouses as adaptations to rural conditions. And so, to check on the health of our edible traditions, one goes to the heartland. Since Crèvecoeur's day, the geographical center of American farm life has moved westward, and the best place to observe the ritual of apple pie at its zenith is at a Midwestern county fair with a serious apple pie contest.

Practically the first thing I saw after arriving at the Buchanan County Fair in eastern Iowa was a black bull galloping free as you please in a rampaging circle that ran from the cattle stalls to the livestock judging arena, around to the midway, past the 4-H exhibit hall, and then back to the pickup that had brought him, not fully broken, from the farm. He made several snorting circuits, once or twice dragging a man who grabbed his trailing halter, but causing no harm to him or anyone else except to the Band Boosters, who had to repitch one corner of their tent, which the bull had grazed, before they could resume selling bandburgers (sloppy Joes) and homemade apple pie and ice cream to raise money for the Independence High School band.

Independence, Iowa, is the seat of Buchanan County and the site of its annual fair, a showpiece of old-fashioned agricultural vigor held in the baking heat of late July when the hay is mostly in and the corn and soybeans are not yet ready to harvest. Similar fairs are staged all over the country during this relatively slow time for farmers, each one an individual expression of the quality of rural life in a single county.

The Buchanan fair is no more typical of the status quo of American agricultural life than any other. Indeed, the town of Independence, although small, with fewer than 6,000 inhabitants, has a definite urban feel to it, stemming partly from its proximity to industrial Waterloo, twenty-three miles to the west, and partly from

otographs by Adelaide de Menil

*A rampaging bull is captured before he causes too much damage.*

its past as a milling center and the Midwest's harness-racing capital. Today, however, the beautiful brick Wapsipinicon Mill stands empty, a casualty of gigantism in the grain trade, and all that remains of the Rush Park racetrack is the show barn, restored and converted into a restaurant. Yet from my room at the Rush Park Motel, which is still within the city limits, I could see fields and smell the unmistakable smell of hogs.

Independence is, above all else, the center of a region that, while practicing modern agriculture with its overwhelming emphasis on machines, has managed to hold on to at least some of its human, cultural traditions. People still have the upper hand in Buchanan County. You can see it at the fairgrounds, which gives space to the collection of the county historical society—antique farm tools, an old-time kitchen, and an early blacksmith shop—but does not, as so many fairs do, have displays of hulking tractors and other modern machinery hauled in by salesmen from John Deere and Massey-Ferguson.

During fair week at Independence you can learn something about traditional farm life—and the vanishing species of farm families who still live it—by driving just a short way out of town on the perfectly perpendicular network of crushed limestone roads that link the spacious fields of corn and soybeans springing up in some of the world's richest topsoil. In this immense grid of unparalleled fecundity, a road that cuts across the others on a diagonal is a landmark. And it is shortly after you have turned off at such an oblique intersection that you arrive at the Priebe family's farm.

Meeting the Priebes takes a minute or two, since the whole clan, assembled for dinner, includes Clifford and Wilma Priebe; their married daughter Bonnie, her husband Mike O'Brien, and their little daughter, Marie; 21-year-old Stan Priebe, who will some day take over the farm's several hundred acres; teen-age live wire Cindy; and two children of grade-school age, Celia and Dale.

When the assembled Priebes sit down to dinner (they would call it supper; "dinner" means lunch in the Corn Belt), they eat almost no food they do not produce themselves. The day I visited, the extremely tasty pork roast came from one of their many hogs; this one had been butchered at a local abattoir called a "locker." The sweet corn on the cob was picked fresh and although not quite ripe enough to satisfy the Priebes' refined expectations, it still surpassed most corn that finds its way to Manhattan retailers. The cabbage for Wilma Priebe's tart slaw came from her large kitchen garden. And there were mashed potatoes and fruit jello and a pitcher of creamy raw milk coaxed by hand from the family milch cow. Dessert was, of course, apple pie, with a crust flaky from lard and a tart filling of early Harvester apples picked from a nearby tree and made elegant with cream (see recipe below). As a menu, the meal was mundane, except for the sheer number of vegetable side dishes. But the freshness of the ingredients and the skill of the cook raised it to a high level. At the Priebes' table, one finds mainline American cookery at its best, the food of the farmhouse, splendid there, close to the soil. But when exported in cans or in the recipe files of Midwestern dieticians to institutional dining rooms or to the pages of women's magazines,

this perilously simple cuisine almost invariably becomes second-rate and insipid.

No doubt Wilma Priebe could make a first-class apple pie from supermarket apples in a city apartment kitchen, but the right context can be important for a cook, and it goes a long way toward enhancing the taste of food. Certainly it would be hard to imagine a better context for appreciating pork roast and apple pie with a lard crust than a farmhouse where hogs get loose during supper and little Dale runs out to shoo them back to their pen.

The Priebes, without intending it, are big on context. Unlike many successful Midwestern farmers, they have not eliminated livestock and confined their operation to profitable, relatively undemanding grains. Pork and beef and broiler chickens all prosper on their land. There is a bull called Delbert, a pet mule, and a goat whose milk is used to feed the pet raccoon.

The pet raccoon is not as tame as Cindy Priebe would like it to be, but she hasn't had the time to work with it properly because, she says, she's been too busy with 4-H work. Her club has been emphasizing sewing. The club also puts her in touch with neighbor girls she might not otherwise see too often since she attends a parochial high school in town. Through 4-H camp counseling and other statewide events, she has acquired contacts throughout Iowa, while her brother Stan visited a big farm in Mount Upton, New York, on a 4-H exchange.

On a national scale, 4-H (for head, heart, hands, health) has five million schoolchildren as members; only 25 percent of them, however, live on working farms. Administered under the Department of Agriculture's Cooperative Extension program, 4-H is no longer a supplementary education service reserved for farm kids. There is even a 4-H program in New York County, New York (Manhattan). With the dramatic exodus from farms after World War II, 4-H has moved into nonrural areas because that is where the children are. But in a rural county such as Buchanan, 4-H still functions in the old way and reaches its culmination at the annual fair.

All the livestock shown at the Buchanan County fair is exhibited by 4-H members. Parents may help with the elaborate grooming of the animals, but their children have spent hours and hours working with the cattle and sheep and hogs, feeding them to produce a prize shape and training them to behave properly for the judges.

A 4-H sponsored garden contest was won in 1980 by Sandy Oliphant, who managed to cultivate staked tomatoes, purple beans (they turn green when cooked, but their purple color makes them easy to locate for picking), Concord grapes, black raspberries, zucchini, purple kohlrabi, cabbage, broccoli, cauliflower, acorn squash, pumpkin, bell peppers, cucumbers, and a patch of carrots left unthinned to show children with thumbs less green why thinning is necessary for producing big carrots.

There are 4-H sponsored competitions in almost every imaginable area from house plants to geology to photography, including a "self-determined" class for the recognition of unclassified achievement. The 1980 self-determined winner was a scrapbook compiled over several years by Rachelle Reid, who adopted wild burros from the federal government and recorded the experience in progressively more sophisticated essays written as she and the burros grew older.

In the area of prepared foods, the Buchanan County 4-H conducted judgings in seventeen categories of canned fruit, eleven categories of pickles and relishes, and thirty-three categories of baked goods, ranging from white bread to rhubarb cake. Indeed, the only food event at the fair not sponsored by 4-H is the pie contest, which is run by the Buchanan County Porkettes. Wives of pork producers, the Porkettes volunteer their time to promote the use of pork products. They give food demonstrations with pork in supermarkets. They work with pigskin. And at the fair, under the aegis of Lady Loinette, the nattily skirted and jacketed sow that is their symbol, they superintended the baking of thirty-nine pies. According to official contest rules, every crust had to contain lard, and the contest was judged with meticulous expertise by two home economists and crowned by an auction in the fair's livestock show ring. Local bankers and seed merchants bid hot and heavy, spending $60 and more to get a pie and some good PR in the bargain.

Virtue was rewarded. Wilma Priebe won the blue ribbon in the adult division. Her daughter Cindy took the junior division championship. Their crusts flaked; their fillings fulfilled every criterion of excellence. In one county in Iowa, at least, people are keeping the American heritage in apple pie order.

*Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.*

**Wilma Priebe's Grand Champion Apple Pie**
Buchanan County Fair, Independence, Iowa, 1980

*Crust*

3 cups flour
1 teaspoon salt
1 cup (8 ounces) lard
1 tablespoon vinegar
5 tablespoons water (or milk for golden crust)
1 egg

1. Mix flour, salt, and lard together in a bowl, cutting in the lard with a pastry blender until you produce a crumbly texture like that of uncooked oatmeal.
2. In another bowl, mix vinegar, water (or milk), and egg with a rotary beater. Then blend into the flour-lard mixture a little at a time. Blend well.
3. Divide dough into four equal pieces, enough for two double-crusted, 9-inch pies. This dough rolls easily and will take a lot of handling and still make a flaky crust. Refrigerate or freeze until needed.

*Filling*

3½ cups peeled, cored, and sliced tart cooking apples
1 cup sugar
2 tablespoons flour
1 teaspoon vanilla
⅔ cup half-and-half

1. Combine all ingredients in a bowl and mix together thoroughly. This is enough filling for one 9-inch pie.

*Final Assembly and Baking*

1. Preheat oven to 450 degrees
2. Roll out one of the balls of dough into a circle about one-eighth inch thick. Dust the work surface lightly with flour before you start. Use more flour as necessary to prevent sticking. When you have a circle of dough large enough to fill and slightly overlap the edge of a 9-inch pie pan, transfer the crust to the ungreased pie pan. Trim off excess. Crimp along the edge with tines of a fork or your finger, pressing dough to the flange of the pan.
3. Place apple filling in the pie pan, spreading it evenly over the dough.
4. Roll out another ball of dough as above. Moisten the edge of the bottom crust with a small amount of water. Place the top crust over the pie. Press around the edges. Slash through the crust in a few places or make a small hole in the center.
5. Bake 10 minutes. Then reduce oven temperature to 350 degrees and bake another 30 to 40 minutes, until crust is nicely browned and the apples feel tender when probed with a trussing needle through the top crust. Cool on a rack.

Yield: One 9-inch double-crusted pie, plus dough for a second double-crusted pie

# "This may be the only computer center where one of the job hazards is seasickness."

The Hollis Hedberg, Gulf's own floating computer center.

"This computer center happens to be on the *Hollis Hedberg*," says Gulf Research Geophysicist John McDonald. "It's the only research vessel in the industry that has complete data processing right on board. And that makes all the difference.

"The typical oil exploration ship is equipped only to record raw data from whatever equipment it has on board to detect oil deposits under the ocean floor. Usually they have seismic sounding gear, occasionally magnetometers and gravity meters. The raw data gets sent to an onshore computer center for analysis, and by the time analysis is complete, the ship could be a thousand miles away.

*"On-board computers help you learn a lot more, a lot faster."*

"By contrast, the *Hedberg* has a full complement of recording equipment, including hydrocarbon 'sniffers,' and with computers right on board, we can make a preliminary analysis immediately. If it looks good, we go back for a second look at that location.

"It could take five or six years between the time you find an oil deposit and the time you actually start drilling for oil, so any time we save in exploration puts the country that much closer to a new supply of petroleum.

"It's a real challenge, trying to find that invisible spot under the seabed that's likely to produce oil. But the *Hedberg* is one of the best ways there is of finding it."

OM10
OLYMPUS
MANUAL ADAPTER
AUTO-S
OM F.ZUIKO
OLYMPUS

# Why the Olympus OM-10 should be your first quality automatic SLR.

**1. Ease of operation.** It's this simple: No 35mm Single Lens Reflex camera is easier to use than the fully automatic Olympus OM-10. The genius of Chief Designer Maitani has created a camera so easy, so automatic, that you'll see superb results the very first time you use it.

**2. Great pictures, automatically.** You'll take brilliant 35mm photographs with the OM-10... automatically. Because the OM-10's state-of-the-art electronics set the correct exposure for you, nothing is left to chance. And you're left free to simply focus and shoot.

**3. Off-the-film metering.** OTF sounds deeply technical but it means simply this: The OM-10 measures the light during the exposure *off the film itself*. And it continues to measure and adjust exposure even after you press the shutter release. Olympus made the world's first 35mm SLR that keeps working–automatically–when you need it most.

**4. Room to grow.** When you want the creativity that comes with full exposure control, your OM-10 is ready. With the manual adapter you can select any combination of shutter speed and aperture–to get the exact effect desired.

**5. The right price.** The fully automatic OM-10 offers features unavailable on many of the highest-priced SLR's...features you wouldn't expect at *any* price.

**6. The right size and weight.** Bulky, heavy cameras have caused many people to decide against stepping up to an SLR. These problems don't exist with the OM-10, a camera that's part of the world's first compact 35mm SLR system. Olympus started the move to smaller, lighter, simpler cameras.

**7. Flash exposure indicator.** More valuable technical innovation. A light inside the OM-10's viewfinder tells you if you've taken a correctly exposed photo with your Olympus flash. That's a feature just not found on most cameras.

**8. More room to grow.** Unlike many SLR's, the OM-10 gives you a choice of 33 quality Olympus lenses. These lenses are the same lenses designed for the most expensive Olympus cameras.

**9. The OM System.** The lenses mentioned above are just a part of the remarkable OM System... the world's largest array of compact accessories made to fit a 35mm SLR. From flashes to carrying cases, lenses to auto. winders, more than 300 accessories in the OM System are ready for your OM-10.

**10. Interchangeablity.** If you do decide to move up to an OM-1 or OM-2, you'll be able to take along virtually every accessory–and *all* the lenses–you've bought for your OM-10.

**11. Failsafe electronic operation.** A comprehensive group of safety devices linked to a pair of high-capacity electronic brains make the prospect of spoiled photos and wasted film unlikely. More than a dozen of these safety devices work automatically toward one goal: Helping you take terrific photographs.

**12. The best reason of all.** Because it's an Olympus. Designed from a clean sheet of paper to be a breakthrough in camera engineering, to be an integral part of the Olympus tradition of excellence by design...a tradition we invite you to share. For complete information on the OM-10, see your dealer. Or write Olympus, Woodbury, NY 11797.

**Jack M. Kugelmass** learned of the mostly poor and elderly Jews who live and worship in New York City's forbidding South Bronx from Yoav Levy, the photographer on the story. The two are currently putting together a book on this subject. Researching the article out in the streets was a change of pace for Kugelmass, who had recently received his Ph.D. from the New School for Social Research. His anthropology dissertation on the Jews of prewar Poland was based on published memoirs found in libraries. Kugelmass conducts seminars on the ethnography of East European Jewry at the Max Weinreich Center for Advanced Jewish Studies at the YIVO Institute in New York City. An avid cyclist, he has been studying urban bicycle messengers—as a participant-observer.

An enthusiastic birder and overall student of natural history, **John Kricher** first became interested in the nature of weeds while doing research on the diversity of bird species in a recently abandoned field. He subsequently received his Ph.D. from Rutgers University and is currently associate professor of biology at Wheaton College in Norton, Massachusetts. His present research topics include an analysis of range expansion of several passerine bird species in New England and studies of ecosystem perturbation in relation to chemical compounds. Kricher lives with his wife and a pet collared peccary, which impresses him "both with its intelligence and its ability to thrive in the New England winter."

THE GLENLIVET 12 YEARS OLD SCOTCH WHISKY

Discover more.

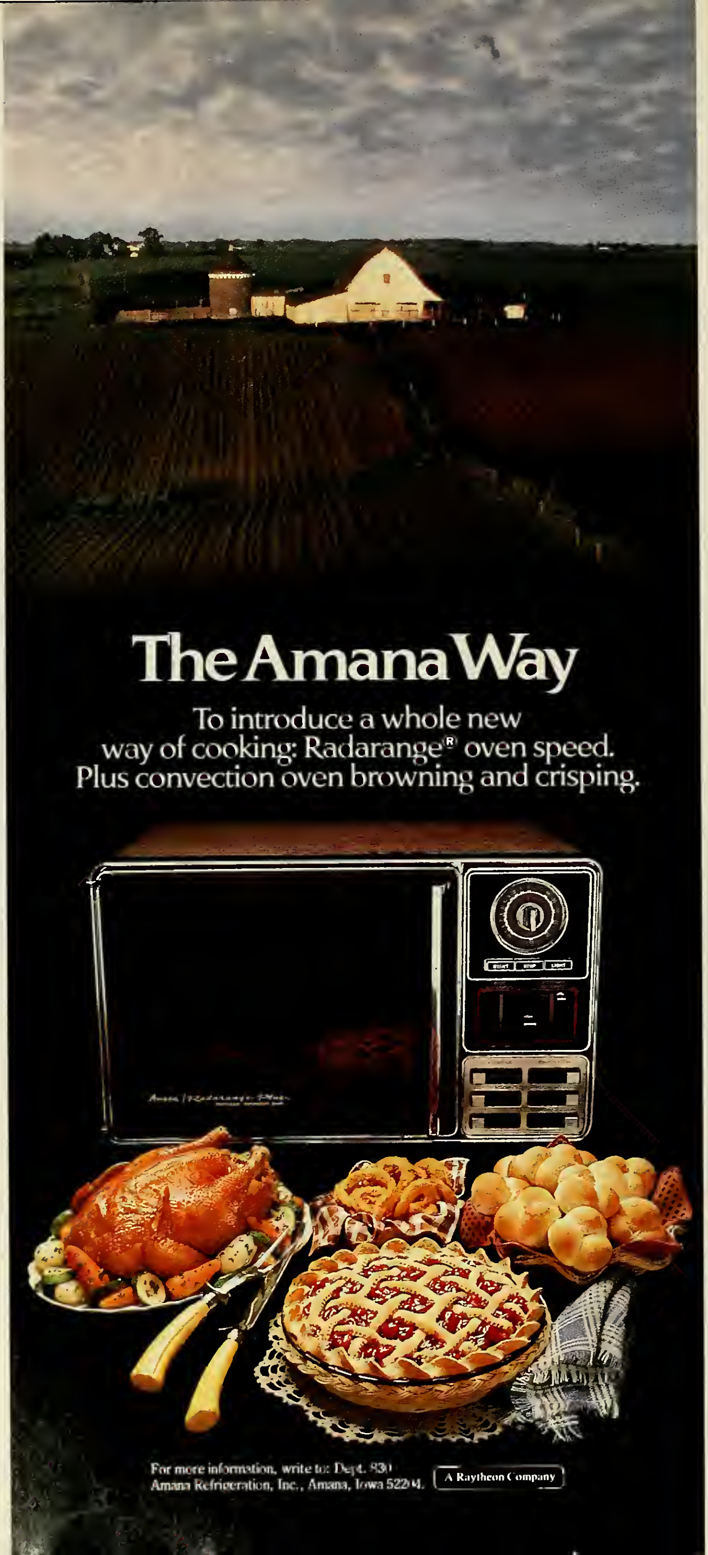
Let your mature taste lead you from the finest premium Scotch on up to the most expensive 12-year-old Scotch in the world. The Glenlivet. The ultimate in Scotch.

Most premium Scotch is blended and depends on several whiskies for taste and smoothness.

Yet the unblended character of The Glenlivet is noble enough to stand alone. In this distinctive Scotch whisky you'll experience an exceptional smoothness and full-bodied richness, unmatched in all other premium Scotch.

Try the taste beyond premium Scotch.

**The Glenlivet**
Unchanged since 1824.



The Amana Way
To introduce a whole new
way of cooking: Radarange® oven speed.
Plus convection oven browning and crisping.
Amana Radarange Plus
START STOP LIGHT

Amana Refrigeration, Inc., Amana, Iowa 52204.
A Raytheon Company

They were an unyielding lot, the folks who settled Amana, Iowa. They never could take to compromise.

Today, our new Radarange Plus™ microwave convection oven is proof nothing's changed.

We could have compromised. By simply adding a browning element.

But we didn't.

Instead, we developed a whole new kind of oven. One that's part microwave, part convection. The microwave part cooks the food fast. The convection part circulates hot air around the food, browning and crisping the outside.

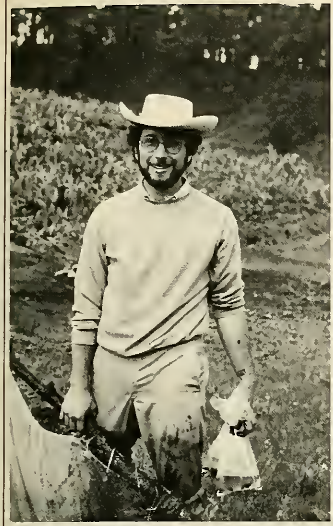
The result is chicken that looks like it came out of a roaster. Onion rings and French fries that look like they came out of a deep fryer. And baked goods that look like they came out of a bakery.

And no matter what you cook, clean-up's easy because the interior is stainless steel.

Our new Radarange Plus microwave convection oven. Cooks by microwave, cooks by convection, or cooks by both. It's a whole new way of cooking. It's The Amana Way.

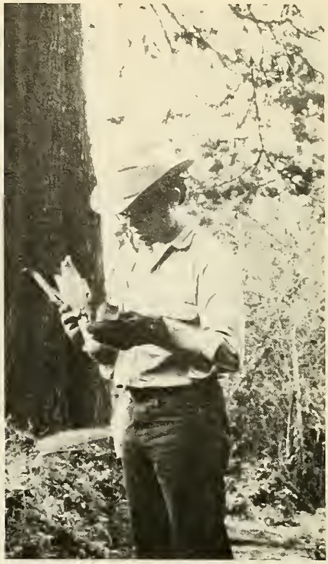
**Amana®**

Every part of every product we make is backed by a century-old tradition of fine craftsmanship.

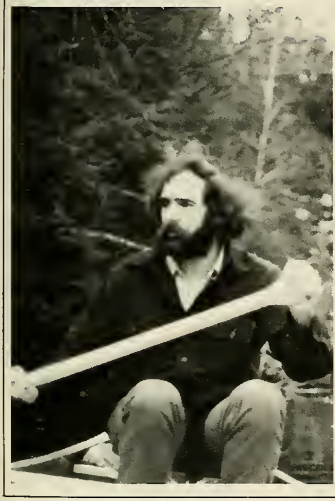


A spare-time jazz singer, **James Hanken** recently received his Ph.D. in zoology from the University of California at Berkeley. He is now on his way to Dalhousie University in Halifax, Nova Scotia, where he will serve as a Killam Postdoctoral Fellow, and continue his research on miniaturization in vertebrates, particularly salamanders. Hanken is also a semiprofessional photographer, having had his work published in several books and magazines and winning a first prize in the *Natural History* photographic competition of 1979.

The ecology and evolutionary biology of plethodontid salamanders in North and Central America has been a strong interest of **James F. Lynch.** A research biologist at the Smithsonian Institution, Lynch has also pursued fieldwork on the community ecology of ants and the island ecology of birds that inhabit patches of forest in eastern North America.



**David B. Wake** is a professor of zoology and director of the Museum of Vertebrate Zoology at the University of California, Berkeley. His work has emphasized the evolution of adaptive morphology. He has studied salamanders since his first year in graduate school, an interest that developed into investigating the systematics of plethodontid salamanders, using comparative morphometric, osteological, allozymic, developmental, and immunological approaches.



Physicist **Michael Oppenheimer** is affiliated with the Harvard-Smithsonian Center for Astrophysics and lectures on astronomy at Harvard University. While doing research on the composition of comet gas he became intrigued with the history of comets and that, in turn, led to the article in this issue. Oppenheimer got a bachelor's degree in chemistry from MIT and a Ph.D. in chemical physics from the University of Chicago. He has written for *Natural History* before (see "What are Comets Made of?" March 1978, page 42). Coauthor **Leonie Haimson** is a recent Radcliffe College graduate in social studies who has launched a career as a freelance writer. Among other work, she has written an as-yet-unpublished book on hysteria among women in nineteenth-century America.

# Nutrition and Brain Development

*Malnutrition early in life can cause developmental abnormalities within the brain, but these negative effects can often be reversed by proper nutrition and exposure to an enriched environment*

### by Myron Winick

During the late 1950s and early 1960s there was a great deal of concern about the possibility that malnutrition during very early life might result in permanently retarded mental development. Studies from South Africa, Mexico, Chile, and other places suggested that children hospitalized during infancy for malnutrition had reduced I.Q. scores and poor academic performance when they reached school age. In a world in which 300 million children were estimated to have suffered significant malnutrition in infancy, this presented a potential problem of enormous magnitude.

At the same time, other studies clearly showed that early malnutrition profoundly retarded physical growth and markedly curtailed the expected increase in head circumference. Hence the implications were that the body was not reaching expected height and that the brain was not reaching expected size.

Experiments quickly undertaken in animals confirmed the observations in human populations and extended them by showing that animals undernourished during the nursing period had reduced brain sizes, a reduced amount of brain myelin content (the covering sheath of nerve fibers), and a reduced number of brain cells. In addition, the number and complexity of neuronal connections were reduced. Most of these changes were found to be permanent unless rehabilitation began very early in life.

These same experimental animals were shown to exhibit abnormal behavior: they were unable to run a maze properly or to extinguish a learned reflex, and again, this behavior persisted into adult life even if the animals were rehabilitated after their early exposure to malnutrition. Thus a single exposure to severe food restriction during the neonatal period not only impaired brain growth and function but also induced permanent changes in brain structure and in the animals' behavior.

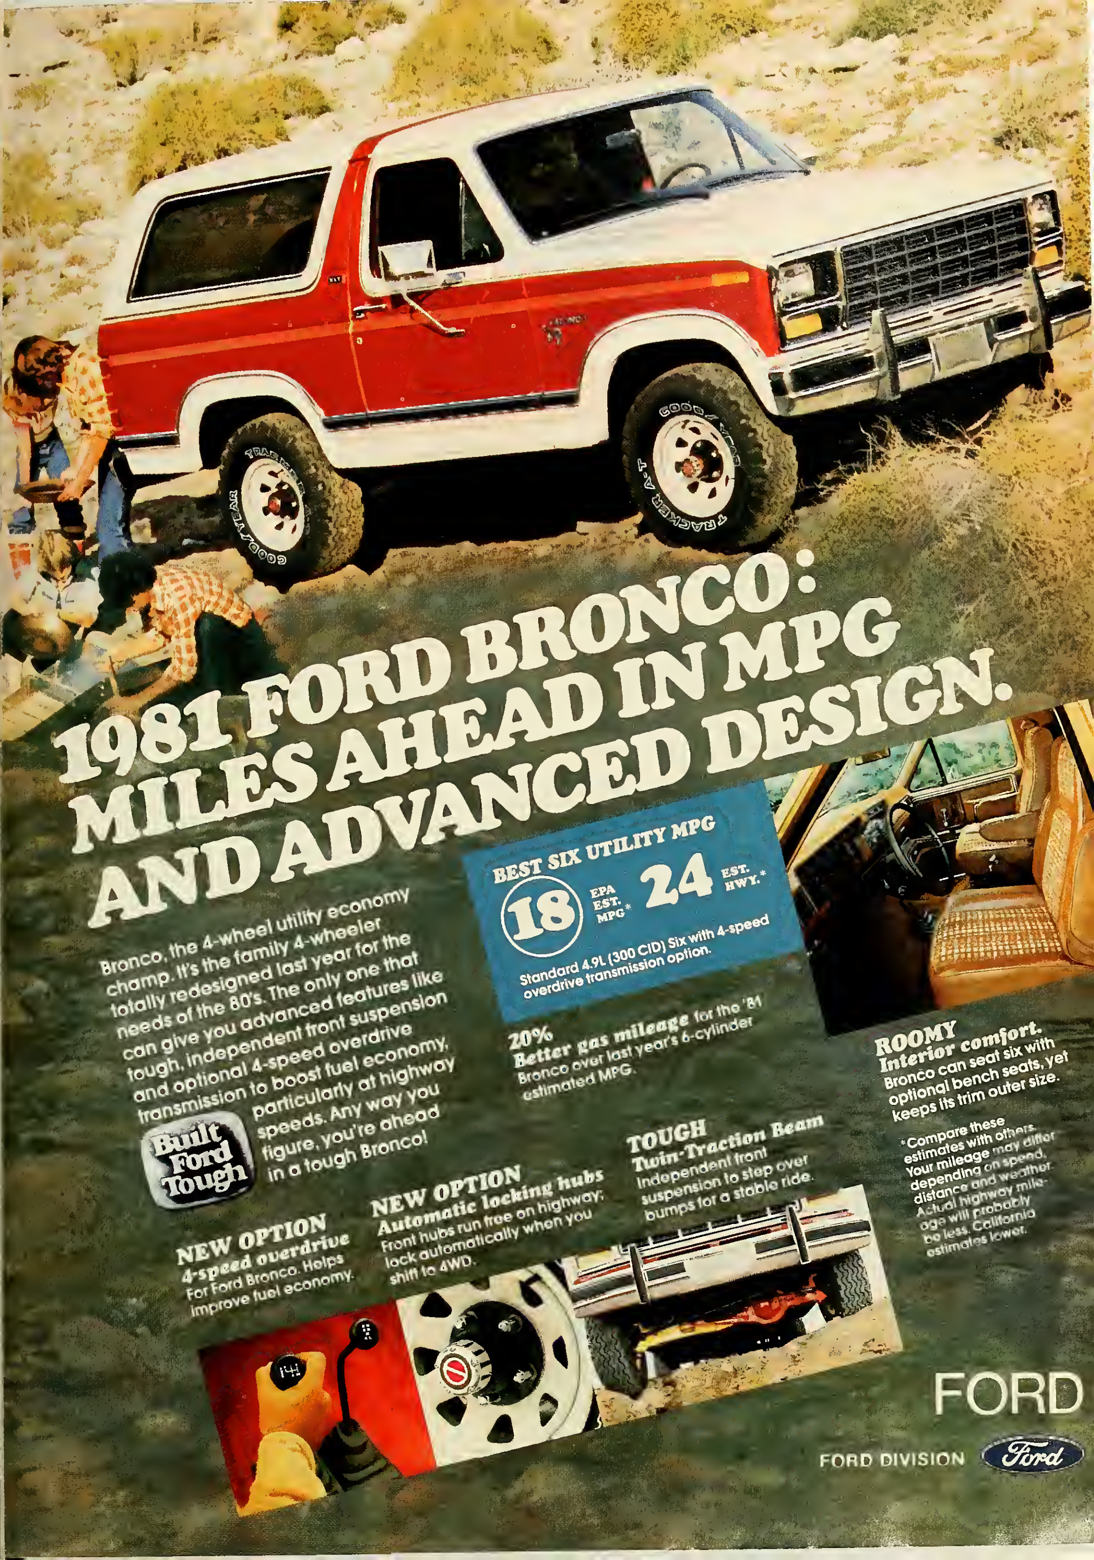
These studies raised obvious questions about human malnutrition, especially as seen in Third World countries. Does malnutrition retard growth and alter the structure of the *human* brain? What is the critical time during which malnutrition must occur in order to cause such changes? Do structural and biochemical changes induced by malnutrition lead in some way to the developmental changes that have been described in children?

Before studies could be undertaken to examine the effects of early malnutrition on the human brain, the normal pattern of cellular growth had to be determined. To do this the brains of children who died in accidents, from accidental poisonings, or from other catastrophic events were examined. By analyzing these brains for DNA content and dividing by the known amount of DNA in any human diploid cell (6.0 millionths of a gram), the number of cells in the human brain at any given time was determined.

The data indicated that the number of human brain cells reached their maximum by about eighteen months of age. Moreover, like the findings in experimental animals, there were three distinct periods of cellular growth in the human brain. The earliest period, occurring before birth, was characterized by a rapid proliferation of cells with little or no increase in their size. The second period, from birth to eighteen months, was characterized by a progressive decrease in cell proliferation and a concomitant increase in cell size. The third period, from eighteen months until beyond three years, was characterized by cell enlargement only, with no further increase in cell number. Additional studies indicated that the increased number of cells during the first period could be divided into an early increase in the number of neurons, peaking at about twenty-six weeks of gestation, and a later increase in the number of glia, or supporting cells, peaking around birth.

Thus human brain growth could be characterized by a progression of cellular events. First the neurons themselves rapidly divide and increase their number, then the glial cells reach maximum rates of cell division, and finally cells begin to enlarge as myelin is deposited and as branches grow and arborize, building the ultimate network of axonal and dendritic connections that characterizes the mature brain.

It was obvious from these studies that if one wanted to study the effect of malnutrition on the cellular development of the human brain, the time when malnutrition occurred was critical. The earlier the malnutrition, the greater the potential for interfering with cell division and ultimately reducing the number of brain cells. In



# 1981 FORD BRONCO: MILES AHEAD IN MPG AND ADVANCED DESIGN.

Bronco, the 4-wheel utility economy champ. It's the family 4-wheeler totally redesigned last year for the needs of the 80's. The only one that can give you advanced features like tough, independent front suspension and optional 4-speed overdrive transmission to boost fuel economy, particularly at highway speeds. Any way you figure, you're ahead in a tough Bronco!

**BEST SIX UTILITY MPG**

**18** EPA EST. MPG* **24** EST. HWY.*

Standard 4.9L (300 CID) Six with 4-speed overdrive transmission option.

**20%**
***Better gas mileage*** for the '81 Bronco over last year's 6-cylinder estimated MPG.

**ROOMY**
***Interior comfort.*** Bronco can seat six with optional bench seats, yet keeps its trim outer size.

*Compare these estimates with others. Your mileage may differ depending on speed, distance and weather. Actual highway mileage will probably be less. California estimates lower.

**TOUGH**
***Twin-Traction Beam*** Independent front suspension to step over bumps for a stable ride.

**NEW OPTION**
***Automatic locking hubs*** Front hubs run free on highway; lock automatically when you shift to 4WD.

**NEW OPTION**
***4-speed overdrive*** For Ford Bronco. Helps improve fuel economy.

SMALL WONDER

NIKON ROOF PRISM COMPACT BINOCULARS

the late 1960s and early 1970s a series of studies in Chile established those facts. Brains of children who died of severe malnutrition during the first year of life (infantile marasmus) were examined. The data clearly showed that the number of cells in the brains of these children was reduced from the norm. This reduction was noted in all of the brain regions examined and was of a similar magnitude to the reduction noted in the brains of animals severely malnourished during the neonatal period. In addition, again paralleling the findings in animals, the deposition of myelin and the extent of dendritic arborizations were found to be reduced.

Without question, early malnutrition as it occurred in the Third World was producing cellular and structural changes in the human brain. By correlating the actual brain changes with the head circumferences of those children who died of malnutrition it could be shown that the head circumference was an accurate reflection of the actual brain weight and the number of brain cells. Accordingly, the more severe the cellular damage, the smaller the head circumference.

With millions of children surviving early malnutrition but left with two of its major results—short stature and reduced head circumference—these data again raised the question of the adequacy of brain development in a large segment of the world's children. In addition, these findings, coupled with previous findings that similarly malnourished children who survived showed permanent developmental abnormalities and that the severity of these abnormalities also correlated with the degree of reduction in head circumference, raised the question of a direct association between the structural changes and the functional outcome.

In the early 1970s several studies began to suggest that this view of the effects of early malnutrition was probably an oversimplification. Animal psychologists noted that behavioral abnormalities identical to those exhibited by animals malnourished early in life occurred in animals that were not malnourished but were reared in isolation. Moreover, if the animals were stimulated in a variety of ways, the expected behavioral changes induced by neonatal malnutrition did not occur. The psychologists postulated that there was an interaction between malnutrition and environ-

**Speak German like a Diplomat!**

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign service personnel, that's who.

Now *you* can make a start on learning to speak German with the same materials used by the U.S. Department of State — the Foreign Service Institute's *Programmed introduction to German* and *Basic Course, Continued.*

The FSI spent thousands of dollars and many years developing these materials for use by members of America's diplomatic corps. Today people in all walks of life who need to learn to speak a foreign language are turning to this outstanding audio cassette program.

The Foreign Service Institute's German Course is by far the most effective way to learn German at your convenience and at your own pace. It consists of a series of tape cassettes and accompanying textbook. You simply follow the spoken and written instructions, listening and learning. By the end of the course you'll find yourself learning and speaking entirely in German! A native German speaker, clearly recorded on the cassettes, provides an excellent model to help you develop your skills.

*This course turns your cassette player into a "teaching machine."* With its unique "programmed" learning method, you set your own pace testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes: You may order one or both courses:

☐ **Volume I. Programmed introduction to German,** 9 cassettes, 12 hours and 647-page text, $115.

☐ **Volume II. Basic Course, Continued (More Advanced)** 8 cassettes, 8½ hours and a 333-page text, $98.

(New York State residents add appropriate sales tax.)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD **and mail with your name and address, and a check or money order.** Or charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's German course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the most convenient and most painless way to learn German, return it and we'll refund every penny you paid! Order today!

mental deprivation that accounted for the behavioral abnormalities and, further, that early malnutrition may exert its effects on behavior by "functionally isolating" the animal from its environment, thereby preventing the normal stimuli necessary for proper development from reaching the animal at the proper time.

Several observations in human populations suggest that this hypothesis might be correct. First, malnourished children from Third World countries (the populations that had been primarily investigated) invariably grew up in deprived environments. Second, such children were apathetic and often much less demanding than better-nourished children. Hence they were deprived of even the little attention that was available. Third, and perhaps most important, children who were as malnourished as the investigated Third World children, but who came from more enriched environments, did not show the expected deficits in I.Q. or school achievement.

One study examined United States children with cystic fibrosis, a serious medical condition that is invariably associated with severe early malnutrition. By age five these children had normal I.Q.'s and achievements. Another study investigated children with pyloric stenosis, a condition that also results in severe early malnutrition. Again, their I.Q.'s and achievements were normal. Consequently, the data suggested that although malnutrition early in life could directly retard brain growth and alter brain structure, it did not in itself affect mental development. Only when malnutrition was coupled with a deprived environment were the behavioral effects manifested. These observations raised a crucial question. Could malnourished children growing up in an environment of poverty and deprivation develop normally if they were subsequently exposed to an enriched environment?

In an attempt to answer this question, a study was made of a group of Korean orphans severely malnourished in the first year of life but subsequently adopted by middle-class United States families before the age of three. By the time these children reached school age their average I.Q. scores were 102 and they were achieving at the average level for American children. Although they had not quite reached the levels of similarly adopted Korean children who were well nourished during infancy—whose average

I.Q. was 112—they had shown an enormous amount of recovery. All previous studies on malnourished populations of children, reared in the impoverished environments from which they came, showed I.Q. scores in the sixties or low seventies.

A second study, employing the same populations of Korean orphans, but this time examining children who were adopted after the age of three, demonstrated that I.Q. and achievement dropped in both the previously malnourished and previously well-nourished group, and that the children who had been malnourished in early infancy had I.Q.'s and achievement scores below the United States norms. However, even with adoption after three, these children did significantly better than one would expect had they been returned to their previous environment. Hence the anticipated behavioral effects of early malnutrition occurring in a deprived environment seemingly were either prevented or reversed if the child was subsequently reared in an "enriched" environment.

As might be expected, these studies raised questions about children growing up in deprived environments in the United States. Was the same interaction between poor nutrition and environmental deprivation retarding development in certain segments of our own population? Two groups of children were compared. Both groups had been put in foster care but the children in one group had remained in a single foster home until they were studied, whereas those in the second group had lived in several different foster homes during the study period. The assumption was that a single foster home would provide a more stable environment than multiple foster homes. The results bore this out, demonstrating an average I.Q. score fourteen points lower in the group reared in multiple foster homes.

In carrying out further analysis of the data on foster home children, yet another correlation was noted. A strong relationship was found in the multiple foster home group between I.Q. and height. The smaller the child, the lower the I.Q. This correlation did not, however, hold among the single foster home children. Since severe early malnutrition invariably results in short stature and since the only children whose I.Q. and school performance were reduced were those short children reared in the multiple foster home environment, an interaction between early malnutrition and a deprived environment again seems probable.

In sum, the data so far available suggest that malnutrition early in life exerts two somewhat different effects on the brain. The first is retardation in the rate of cell division and curtailment of myelination and dendritic arborization, resulting in cellular, structural, and biochemical abnormalities within the brain. These changes will occur regardless of the child's environment. The second is a series of behavioral changes that occur as a consequence of the interaction of malnutrition with environmental deprivation. Early malnutrition alone will not produce these changes and enriching the environment even after the interaction has taken place may prevent the changes from occurring.

Some final questions currently under study are whether any chemical events in the brain can be altered by this interaction of nutrition and environment and if such alterations do take place, can they explain abnormal behavior. Recent studies in rats have demonstrated that early malnutrition reduces the concentration of n-acetyl neuraminic acid (NANA), one of many chemical substances secreted by the neurons that may affect the transmission of nerve impulses, in the dendritic tips. Environmental stimulation *increases* the concentration of NANA. In addition, injection of NANA into malnourished animals *increases* its concentration at the synapses of the dendrites and prevents the expected behavioral abnormalities. Consequently, it is possible that both early malnutrition and environmental deprivation work through a single final biochemical pathway and that by altering that pathway behavior can be modified.

In the past thirty years we have come full circle. Whereas initially we believed that early malnutrition invariably led to structural and chemical changes in the brain that, in turn, left permanent behavioral scars, the current data suggest that the behavioral changes are caused by a different mechanism and, much more important from a practical standpoint, that the changes are potentially reversible.

# Science and Jewish Immigration

*Dubious research became the basis for excluding millions of eastern and southern Europeans*

**by Stephen Jay Gould**

In April, 1925, C.B. Davenport, one of America's leading geneticists, wrote to Madison Grant, author of *The Passing of the Great Race,* and the most notorious American racist of the genteel Yankee tradition: "Our ancestors drove Baptists from Massachusetts Bay into Rhode Island, but we have no place to drive the Jews to." If America had become too full to provide places of insulated storage for undesirables, then they must be kept out. Davenport had written Grant to discuss a pressing political problem of the day: the establishment of quotas for immigration to America.

Jews presented a potential problem to ardent restrictionists. After 1890, the character of American immigration had changed markedly. The congenial Englishmen, Germans, and Scandinavians, who predominated before, had been replaced by hordes of poorer, darker, and more unfamiliar people from southern and eastern Europe. The catalog of national stereotypes proclaimed that all these people—primarily Italians, Greeks, Turks, and Slavs—were innately deficient in both intelligence and morality. Arguments for exclusion could be grounded in the eugenic preservation of a threatened American stock. But Jews presented a dilemma. The same racist catalog attributed a number of undesirable traits to them, including avarice and inability to assimilate, but it did not accuse them of stupidity. If innate dullness was to be the "official" scientific rationale for excluding immigrants from eastern and southern Europe, how could the Jews be kept out?

The most attractive possibility lay in claiming that the old catalog had been too generous and that, contrary to its popular stereotype, Jews were stupid after all. Several "scientific" studies conducted between 1910 and 1930, the heyday of the great immigration debate, reached this devoutly desired conclusion. As examples of distorting facts to match expectations or of blindness to obvious alternatives, they are without parallel. This essay is the story of two famous studies, from different nations and with different impact.

H.H. Goddard was the director of research at the Vineland Institute for Feeble-minded Girls and Boys in New Jersey. He viewed himself as a taxonomist of mental deficiency. He concentrated upon "defectives of high grade" who posed special problems because their status just below the borderline of normality rendered their identification more difficult. He invented the term "moron" (from a Greek word for "foolish") to describe people in this category. He believed at the time, although he changed his mind in 1928, that most morons should be confined to institutions for life, kept happy with tasks apportioned to their ability, and above all, prevented from breeding.

Goddard's general method for identifying morons was simplicity itself. Once you had enough familiarity with the beast, you simply looked at one, asked a few questions, and drew your evident conclusions. If they were dead, you asked questions of the living who knew them. If they were dead, or even fictitious, you just looked. Goddard once attacked the poet Edwin Markham for suggesting that "The Man with the Hoe," inspired by Millet's famous painting of a peasant, "came to his condition as the result of social conditions which held him down and made him like the clods that he turned over." Couldn't Markham see that Millet's man was mentally deficient? "The painting is a perfect picture of an imbecile," Goddard remarked. Goddard thought he had a pretty good eye himself, but the main task of identifying morons must be given to women because nature had endowed the fair sex with superior intuition:

> After a person has had considerable experience in this work, he almost gets a sense of what a feeble-minded person is so that he can tell one afar off. The people who are best at this work, and who I believe should do this work, are women. Women seem to have closer observation than men.

In 1912, Goddard was invited by the U.S. Public Health Service to try his skill at identifying morons among arriving immigrants on Ellis Island. Perhaps they could be screened out and sent back, thus reducing the "menace of the feeble-minded." But this time, Goddard brought a new method to supplement his identifications by sight—the Binet tests of intelligence, later to become (at the hands of Lewis M. Terman of Stanford University), the Stanford-Binet scale, or the conventional measure of IQ. Binet had just died in France and would never witness the distortion of a device for identifying children who needed special help in school into an instrument for labeling people with a permanent stamp of inferiority.

Goddard was so encouraged by the success of his preliminary trials that he raised some money and sent two of his women back to Ellis Island in 1913 for a more thorough study. In

# JETTA. 4 IN THE FRONT. 8 IN THE BACK.

Compare the relative merits of today's family cars, and you'll find that a trip to your relatives would be a lot nicer in a Volkswagen Jetta.

In the front, for example, there's room enough for a family of 4 to actually stretch out and enjoy the ride.

In back, there's a trunk big enough to handle 8 suitcases. (Something you don't even get with a Rolls-Royce.)

And under the hood, there's a CIS fuel-injected engine powerful enough to take you from 0 to 50 in just 9.2 seconds. As well as around any trucks, onto any highways and up any mountains you meet along the way.

What's more, even though Road & Track has said it "will embarrass a lot of cars costing a lot more" with its performance and handling, Jetta will never embarrass you at the gas pump.

It gets an EPA estimated $\boxed{25}$ mpg, 40 mpg highway estimate. (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length. Actual highway mileage will probably be less.)

And it gives you front-wheel drive, rack-and-pinion steering, all-independent suspension and classic European styling.

Impressed with Jetta's relative merits?

Your relatives will be, too.

two and a half months, they tested four major groups: thirty-five Jews, twenty-two Hungarians, fifty Italians, and forty-five Russians. The Binet tests produced an astounding result: 83 percent of the Jews, 87 percent of the Russians, 80 percent of the Hungarians, and 79 percent of the Italians were feeble-minded—that is, below mental age twelve (the upper limit of moronity by Goddard's definition). Goddard himself was a bit embarrassed by his own exaggerated success. Weren't his results too good to be true? Could anyone be made to believe that four-fifths of any nation were morons? Goddard played with the numbers a bit, and got his figures down to 40 or 50 percent, but he was still perturbed.

The Jewish sample attracted his greatest interest for two reasons. First, it might resolve the dilemma of the supposedly intelligent Jew and provide a rationale for keeping this undesirable group out. Second, Goddard felt that he could not be accused of bias for the Jewish sample. The other groups had been tested via interpreters, but he had a Yiddish-speaking psychologist for the Jews.

In retrospect, Goddard's conclusions were far more absurd than even he allowed himself to suspect in anxious moments. It became clear, a few years later, that Goddard had constructed a particularly harsh version of the Binet tests. His scores stood well below the rankings of all other revisions. Fully half the people who scored in the low, but normal, range of the Stanford-Binet scale tested as morons on Goddard's scales.

But the greater absurdity arose from Goddard's extraordinary insensitivity to environmental effects, both long-term and immediate, upon test scores. In his view, the Binet tests measured innate intelligence by definition, since they required no reading or writing and made no explicit reference to particular aspects of specific cultures. Caught in this vicious circle of argument, Goddard became blind to the primary reality that surrounded his women on Ellis Island. The redoubtable Ms. Kite approaches a group of frightened men and women—mostly illiterate, few with any knowledge of English, all just off the boat after a grueling journey in steerage—plucks them from the line and asks them to name as many objects as they can, in their own language, within three minutes. Could their poor performance reflect fear, befuddlement, or physical weakness rather than stupidity? Goddard considered the possibility but rejected it:

> What shall we say of the fact that only 45 percent can give sixty words in three minutes, when normal children of 11 years sometimes give 200 words in that time! It is hard to find an explanation except lack of intelligence. . . . How could a person live even 15 years in any environment without learning hundreds of names of which he could certainly think of 60 in three minutes.

Could their failure to identify the date, or even the year, be attributed to anything other than moronity?

> Must we again conclude that the European peasant of the type that immigrates to America pays no attention to the passage of time? That the drudgery of life is so severe that he cares not whether it is January or July, whether it is 1912 or 1906? Is it possible that the person may be of considerable intelligence and yet, because of the peculiarity of his environment, not have acquired this ordinary bit of knowledge, even though the calendar is not in general use on the continent, or is somewhat complicated as in Russia? If so what an environment it must have been!

Goddard wrestled with the issue of this moronic flood. On the one hand, he could see some benefits:

> They do a great deal of work that no one else will do. . . . There is an immense amount of drudgery to be done, an immense amount of work for which we do not wish to pay enough to secure more intelligent workers. . . . May it be that possibly the moron has his place.

But he feared genetic deterioration even more and eventually rejoiced in the tightening of standards that his program had encouraged. In 1917, he reported with pleasure that deportations for mental deficiency had increased by 350 percent in 1913 and 570 percent in 1914 over the average for five preceding years. Morons could be identified at ports of entry and shipped back, but such an inefficient and expensive procedure could never be instituted as general policy. Would it not be better simply to restrict immigration from nations teeming with morons? Goddard suggested that his conclusions "furnish important considerations for future actions both scientific and social as well as legislative." Within ten years, restriction based upon national quotas had become a reality.

Meanwhile, in England, Karl Pear-

DIPLOMAT
MONTBLANC
Diplomat 149
$200

from MONT BLANC

Like the signature of an Old Master, MONTBLANC signifies the genius of fine art — beauty and performance, flawlessly combined in a truly luxurious fountain pen. Softly gleaming gold-plated trim. 14-karat gold nib with rhodium plating, intricately etched. Effortless balance. Perfect contour, designed to make writing an art in itself. Discover the Diplomat 149 or the somewhat smaller Classic 146 ($160*). Write for our brochure describing the complete line of world-famous Montblanc writing instruments.

son had also decided to study the apparent anomaly of Jewish intelligence. Pearson, who had been christened Carl but changed the spelling to proclaim his Marxist allegiance, was an ardent socialist—proving once again that politics is a peculiarly unpredictable business, and that adherents to a philosophy preaching regard for mankind in general need not extend their affection to individual humans in despised groups.

Pearson's study was as ridiculous as Goddard's, but we cannot attribute its errors (as we might, being unreasonably charitable, in Goddard's case) to mathematical naïveté, for Pearson virtually invented the science of statistics. Pearson, the first Galton Professor of Eugenics at University College, London, founded the *Annals of Eugenics* in 1925. He chose to begin its first issue with his study of Jewish immigration, apparently regarding it as a model of sober science and rational social planning. He stated his purpose forthrightly in the opening lines:

> The purport of this memoir is to discuss whether it is desirable in an already crowded country like Great Britain to permit indiscriminate immigration, or, if the conclusion be that it is not, on what grounds discrimination should be based.

If a group generally regarded as intellectually able could be ranked as inferior, then the basic argument for restriction would be greatly enhanced, for who would then defend the groups that everyone considered as stupid? Pearson, however, loudly decried any attempt to attribute motive or prior prejudice to his study. One can only recall Shakespeare's line, "The lady doth protest too much, methinks," when Pearson proclaimed his objectivity so stridently:

> There is only one solution to a problem of this kind, and it lies in the cold light of statistical inquiry. . . . We have no axes to grind, we have no governing body to propitiate by well advertised discoveries; we are paid by nobody to reach results of a given bias. We have no electors, no subscribers to encounter in the market place. We firmly believe that we have no political, no religious and no social prejudices. . . . We rejoice in numbers and figures for their own sake and, subject to human fallibility, collect our data—as all scientists must do—to find out the truth that is in them.

Pearson had invented a statistic so commonly used today that many people probably think it has been available since the dawn of mathematics—the correlation coefficient. This statistic measures the degree of relationship between two features of a set of objects: height versus weight or head circumference versus leg length in a group of humans, for example. Correlation coefficients can range as high as 1.0 (taller people are invariably heavier to the same degree) or as low as 0.0 for no correlation (an increase in height provides no information about weight—a taller person may weigh more, the same, or less, and no prediction can be made from the increase in height alone). Correlation coefficients can also be negative if increase in one variable leads to decrease in the other (if taller people generally weigh less, for example). Pearson's study of Jewish immigration involved the measurement of correlations between a large and motley array of physical and mental characters for children of Jewish immigrants living in London.

Pearson measured everything he imagined might be important in assessing "worthiness." He established four categories for cleanliness of hair: very clean and tidy, clean on the

**You'd expect Italy's airline to come up with something special to Italy.**

**We did.**

Alitalia's 1980 tour brochure offers no fewer than 32 terrific tours to Italy. If you've ever shopped for an Italian tour, you know just how special that really is.

But we don't just offer incredible variety. As Italy's airline, Alitalia gives you the best that Italy has to offer. Expertly selected hotels and restaurants. Superbly planned itineraries. Tours ranging from 9 days/7 nights in Rome for just $200* to 15-day tours like our "Grand Italian," starting at $732*

Ask for your free copy of our big color brochure. It's called "Italy loves you."

You'll love it.

Fine Woodworking
The magazine about making beautiful things out of wood

Woodworkers' delight—A subscription to *Fine Woodworking* brings an abundance of ideas and information on cabinetmaking, carving, marquetry and turning—the tools and techniques, materials and design. Carefully edited, beautifully printed. Join the 200,000 readers of this superb bimonthly magazine by sending your name and address, along with your payment, to The Taunton Press, 52 Church Hill Road, Box 355S4, Newtown, CT 06470. One year $14, two years $26, refundable. For gifts, please include both addresses. Visa or Master Charge accepted.

whole, dirty and untidy, and matted or verminous. He assessed both inner and outer clothing on a similar scale: clean, a little dirty, dirty, and filthy. He then computed correlation coefficients between all measures and was generally disappointed by the low values obtained. He could not understand, for example, why cleanliness of body and hair correlated only .2615 in boys and .2119 in girls, and mused:

> We should naturally have supposed that cleanliness of body and tidiness of hair would be products of maternal environment and so highly correlated. It is singular that they are not. There may be mothers who consider chiefly externals, and so press for tidiness of hair, but it is hard to imagine that those who emphasize cleanliness of body overlook cleanliness of hair.

Pearson concluded his study of physical measures by proclaiming Jewish children inferior to the native stock in height, weight, susceptibility to disease, nutrition, visual acuity, and cleanliness:

> Jewish alien children are not superior to the native Gentile. Indeed, taken all round we should not be exaggerating if we asserted that they were inferior in the great bulk of the categories dealt with.

The only possible justification for admitting them lay in a potentially superior intelligence to overbalance their physical shortcomings.

Pearson therefore studied intelligence by the same type of short and subjective scale that had characterized his measures of physical traits. For intelligence, he relied upon teachers' judgments rated from A to G. Computing the raw averages, he found that Jewish children were not superior to native Gentiles. Jewish boys ranked a bit higher, but the girls scored notably lower than their English classmates. Pearson concluded, with a striking analogy conjuring up all manner of images in retrospect:

> Taken on the average, and regarding both sexes, this alien Jewish population is somewhat inferior physically and mentally to the native population. . . . We know and admit that some of the children of these alien Jews from the academic standpoint have done brilliantly; whether they have the staying power of the native race is another question. No breeder of cattle, however, would purchase an entire herd because he anticipated finding one or two fine specimens included in it; still less would he do it, if his byres and pastures were already full.

But Pearson realized that he was missing one crucial argument. He had already admitted that Jews lived in relative poverty. Suppose intelligence is more a product of environment than inborn worth? Might not the average scores of Jews reflect their disadvantaged lives? Would they not be superior after all if they lived as well as the native English? Pearson recognized that he had to demonstrate the innateness of intelligence to carry his argument for restricted immigration based on irremediable mediocrity.

He turned again to his correlation coefficients. If low intelligence correlated with measures of misery (disease, squalor, and low income, for example), then an environmental basis might be claimed. But if few or no correlations could be found, then intelligence is not affected by environment and must be innate. Pearson computed his correlation coefficients and, as with the physical measures, found very few high values. But this time he was pleased. The correlations produced little beyond the discovery that intelligent children sleep less and tend to breathe more through their nose! He concluded triumphantly:

> There does not exist in the present material any correlation of the slightest consequence between the intelligence of the child and its physique, its health, its parents' care or the economic and sanitary conditions of its home. . . . Intelligence as distinct from mere knowledge stands out as a congenital character. Let us admit finally that the mind of man is for the most part a congenital product, and the factors which determine it are racial and familial. . . . Our material provides no evidence that a lessening of the aliens' poverty, an improvement in their food, or an advance in their cleanliness will substantially alter their average grade of intelligence. . . . It is proper to judge the immigrant by what he is as he arrives, and reject or accept him then.

But conclusions based upon negative evidence are always suspect. Pearson's failure to record correlations between "intelligence" and environment might suggest the true absence of any relationship. But it might also simply mean that his measures were as lousy as the hair in his category 4. Maybe a teacher's assessment doesn't record anything accurately, and its failure to correlate with measures of environment only demonstrates its inadequacy as an index of intelligence. After all, Pearson had already admitted that correlations between physical measures had been disappointingly small. He was too good a statistician to ignore this possibility. So he faced it and dismissed it with one of the worst arguments I have ever read.

Pearson gave three reasons for sticking to his claim that intelligence is innate. The first two were irrelevant: teachers' assessments correlate with Binet test scores, and high correlations between siblings and between parents and children also prove the innateness of intelligence. But Pearson had not given Binet tests to the Jewish children and had not measured their parents' intelligence in any way. These two claims relied upon other studies and could not be transferred to the present case. Pearson appreciated this weakness and therefore advanced a third argument based upon internal evidence: intelligence (teachers' assessment) failed to correlate with environment but it did correlate with other "independent" measures of mental worth.

But what were these other independent measures: believe it or not, Pearson chose "conscientiousness" (also based on teachers' assessments and scored as keen, medium, and dull), and rank in class. How else does a teacher assess "intelligence" if not (in large part) by conscientiousness and rank in class? Pearson's three measures—intelligence, conscientiousness, and rank in class—were redundant assessments of the same thing: the teachers' opinion of their students' worth. But we cannot tell whether these opinions record inborn capacities, environmental advantages, or teachers' prejudices. I doubt that Pearson took his own argument seriously and was doing more than putting on a brave face by this point. In any case, he concluded with an appeal to bar all but the most intelligent of foreign Jews:

> For men with no special ability—above all for such men as religion, social habits, or language keep as a caste apart, there should be no place. They will not be absorbed by, and at the same time strengthen the existing population; they will develop into a parasitic race.

Goddard's and Pearson's studies shared the property of internal contradictions and evident prejudice sufficient enough to dismiss all claims. But they differed in one important respect: social impact. Britain did not enact laws to restrict immigration by racial or national origin. But in America, Goddard and his colleagues won. Goddard's work on Ellis Island had already encouraged immigration officials to reject people for supposed moronity. Five years later, the Army tested 1.75 million World War I recruits with a set of examinations that Goddard helped write and that were composed by a committee meeting at his Vineland Training School. The tabulations did not identify Jews per se but calculated "innate intelligence" by national averages. These absurd tests, which measured linguistic and cultural familiarity with American ways (a story for another month), ranked recent immigrants from southern and eastern Europe well below the English, Germans, and Scandinavians who had arrived long before. The average soldier of most southern and eastern European nations scored as a moron on the Army tests. Since most Jewish immigrants arrived from eastern European nations, quotas based on country of origin eliminated Jews as surely as collegiate quotas based on geographical distribution once barred them from elite campuses.

When quotas were set for the Immigration Restriction Act of 1924, they were cynically calculated at 2 percent of people from each nation present in America at the census of 1890, not at the most recent count of 1920. Since few southern and eastern Europeans had arrived by 1890, these quotas effectively reduced the influx of Slavs, Italians, and Jews to a trickle. Restriction was in the air and would have occurred anyway. But the peculiar character and intent of the 1924 quotas were largely a result of propaganda issued by Goddard and his eugenical colleagues.

What effect did the quotas have in retrospect? Allan Chase, author of *The Legacy of Malthus*, the finest book on the history of scientific racism in America, has estimated that the quotas barred up to six million southern, central, and eastern Europeans between 1924 and the outbreak of World War II (assuming that immigration had continued at its pre-1924 rate). We know what happened to many who wanted to leave but had no place to go. The pathways to destruction are often indirect, but ideas can be agents as surely as guns and bombs.

# Christmas in Jerusalem

*Experiencing the sacred in the Holy Land is, in itself, a miracle*

**by Colin Turnbull**

It is remarkable that such a vital and far-reaching institution as tourism should have escaped the same degree of attention that social scientists give to institutions of lesser consequence. Here is an institution, virtually ignored, that carries millions of human beings backward and forward across the world every year, crisscrossing cultural, linguistic, political, economic, and religious lines with systematic abandon (systematic at least so far as group tours and professionally arranged tours are concerned).

Significantly, serious attention is at last being given to another long-neglected institution, the pilgrimage. Anthropologists, attracted by the exotic and seemingly disinterested in what is right under their noses, may find, however, that the pilgrimage is not as exotic as they think; they may find it alive and well but in the guise of "tourism." Many tourists are engaged in a quest just as much as are pilgrims although, largely because of what they have been told by the tourist industry, they may state their goals as escape, relaxation, and pleasure.

The quest of the tourist is, I believe, often a quest for the sacred, and with this in mind, a colleague and I decided to take a year away from academia and travel around the world, letting circumstances decide whether we were pilgrims or tourists, whether our quest was sacred or secular, and by observing ourselves and our fellow tourist/pilgrims, begin to come to grips with the many far-reaching effects, often unintended and unexpected, that both institutions have on society.

In taking turns to say where in the world we would like to visit, my colleague and I found there was a great deal of agreement between us. Our respective choices were in several instances related directly to religious behavior in cultures where neither of us had worked as anthropologists. It became clear that while personal pleasure and satisfaction were our stated objectives, fulfillment of some kind was an essential part of the goal. At this stage our plans began to look more and more like a research project, and the comparison between pilgrimage and tourism was inescapable.

Although we felt the concept was worth developing into a full-scale research proposal this in no way altered our fundamental position. We clarified certain ideas, but we were also compelled to present plans of action with a detail we knew could never be foreseen. In any case, the foundation to which we submitted the proposal simply could not accept that one of the qualifications we gave for venturing into an area such as Polynesia was that neither of us knew anything about the region except that it is supposed to have idyllic beaches, a friendly and hospitable population, and magnificent cuisine. Yet plainly, if we were to test tourist perceptions by participant observation, we had to be as uninformed about our destination as most tourists and to have similar hedonistic objectives. It is hardly surprising that the project was not funded, but by the time we were notified of this detail we were into our fifth month in the field. And by then we had already reverted to our original plan of passing one year pleasurably without any academic or foundation guidelines to hamper us.

It was a geographical coincidence that Israel was the first stopover on our itinerary, but one that immediately brought us into contact with many of the very real dangers inherent in tourism—some inescapably rooted in the brief duration of the sojourn of most tourists. (In the Mediterranean area Americans in particular are estimated to spend an average of no more than 2.6 days in any one country.) The prime danger of course lies not only in the superficial impressions that tourists get of people and places nor even in the possible, some would say probable, falsity of their understanding of what they see. It lies more in the intensity with which they receive these impressions, whose essential novelty, however true or false, makes them so vivid that they quickly assume the reality of truth in the mind of the tourist. This "truth," and for tourists, of course, it *is* true, they propagate with enthusiasm on their return home: to fellow classmates, at church meetings, at club or business dinners. But are tourists always wrong, are their impressions always so superficial?

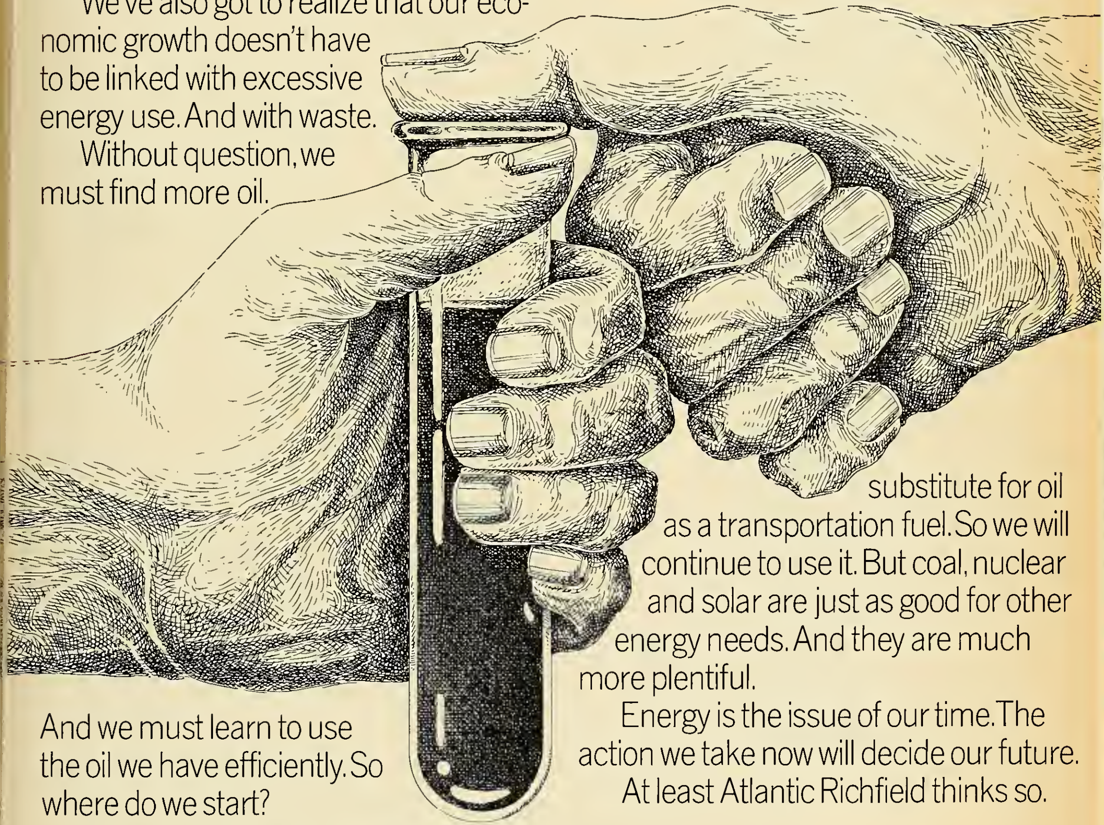
Christian tourists in Israel might well be forgiven for getting, very quickly, the distinct impression that not much has changed in two thousand years and that "Hotel Full" signs are being put up for their exclusive benefit. For Israel is a country at war, and although much of the atmosphere of hostility that pervades the country, and much of the discomfiting omnipresence of heavily armed soldiers is obviously due to this factor rather than to any anti-Christian sentiment, the hostile impression is likely to have a

# Some say the answer is oil exploration. Some say the answer is conservation. For once, everybody is right.

It is exploration. It is conservation. It is alternate energy sources. And it's more.

We've also got to realize that our economic growth doesn't have to be linked with excessive energy use. And with waste.

Without question, we must find more oil.



And we must learn to use the oil we have efficiently. So where do we start?

Scientists say there are billions of barrels of oil still undiscovered in the United States. We have the technology to find it.

Exploration and development will cost billions. But the money is available.

Even so, the most forceful domestic program won't be enough to meet the coming demand.

Nobody uses as much oil as America. Oil provides half of our energy needs. And half of that goes into transportation.

Smaller cars help. So do mileage standards. And we're getting there. But we still have a long way to go.

Right now, there's no economical substitute for oil as a transportation fuel. So we will continue to use it. But coal, nuclear and solar are just as good for other energy needs. And they are much more plentiful.

Energy is the issue of our time. The action we take now will decide our future.

At least Atlantic Richfield thinks so.

**There are no easy answers.**

more lasting effect than the rationalization. Similarly, the Israelis might be forgiven for thinking that Christians, to judge by much tourist behavior, are still a bunch of troublemakers, consciously and unconsciously disrupting the process of efficient government at a time when there is disruption enough. Evidence to support both attitudes is easily found once the attitude has been formed, and a real and enduring animosity can arise all too readily.

For the purposes of this trip I certainly did not consider myself a Christian pilgrim, and I thought I was equally detached from any interest in my cultural and religious history when stretched that far from pagan Scotland. So it was with some surprise that I observed how all this changed.

I found that in a country such as Israel, plainly not a place for the carefree holiday of conventional tourism, tourists are almost instantly compelled to adopt attitudes and opinions whether they want to or not. I began adopting both political and religious stances (or perhaps I was discovering political and religious identities) that were never held previously at a conscious level, even before I boarded the plane at Charles de Gaulle airport.

All of a sudden, for the first time in my life, it came to me that I was a Gentile. It was plain that a miracle had occurred—an agnostic had unwittingly been made to feel like a Christian! That is the power of opposition, and since tourists are, except in exclusively touristic resorts, always a minority in opposition to others, they are constantly being forced to assume an identity, being made to feel more American or whatever, white or black, tall or short, rich or poor, depending upon the nature of the opposition between them and the people whose country they are visiting. The very real danger, not insignificant in terms of international relationships, is that this inherent opposition often manifests itself in hostility, however imaginary or ill-founded.

Having discovered, much to my surprise, that after a long period of neglect I was still a Christian, I began to feel more like a pilgrim. This transformation was completed on my arrival in Jerusalem late that night. The cab ride from Tel Aviv was strangely exciting since it was almost pitch dark. Nonetheless, I filled in the darkness with recollections recalled from the sepia-toned photographs in the Bible of my childhood: deserts, hilly barren land, dusty mud-walled buildings and villages, donkeys, and shadowy figures wearing long, flowing robes. Had it been daylight, my imagery would not have been far different. Soon there was a glow in the sky, lots of stars in the east, and we were suddenly under the walls of the old city of Jerusalem, following them past the Damascus Gate to Herod's Gate, where we turned off into a little side street and pulled up at the Holy Land Hotel. In the light of the street lamps, Jerusalem was as sepia-toned as those photographs, people wore the same long robes, and I was reminded of the life-sized Nativity scenes that fill our churches and department store windows every Christmas. The Christmas feeling was completed when the hotel, despite our reservations, said they were full. However, they suggested, not exactly a stable, but a humble adjoining annex where we did indeed find shelter.

The Christmas spirit was quickly dampened the next day. Setting off early with the enthusiasm of a pilgrim, and with my rediscovered identity as a Christian, I found that within the walls of the old city the stores were as colorful and bright with tinsel as any New York department store—and just as full of junk being sold at ludicrous prices to Christmas shoppers (tourists) who seemed consumed by a compulsion to buy something or everything. I began to feel less Christian. Both the Christian and the Christmas spirit were further dispelled in the one place I thought might possibly revive them—the tomb of the Holy Sepulcher—partly because of the behavior of my fellow tourists, who seemed to manifest a blatant lack of respect for the sacred by their flagrant use of cameras, despite signs prohibiting them. I found the flash gun particularly offensive, illuminating as it sometimes did people at prayer, invading their privacy and despoiling their sanctity. Other tourists pushed and shoved in a very un-Christian way, using shoulders and elbows to force a way through the narrow entrance to the sepulcher itself. Occasionally a minor fight broke out, accompanied by swearing and gestures that were anything but sacred.

The clerics in charge, far from restoring an air of sanctity, dispelled any illusion of holiness by themselves setting the pattern for aggressive behavior. One brown-robed, heavily

# Managing Chemical Wastes

## What the chemical industry is doing to improve waste-disposal methods

**America's chemical companies have already invested hundreds of millions of dollars in safer, better waste-disposal methods. We'll spend over *$2 billion* more on waste-disposal facilities in the next two years. Here's how we're advancing the "state of the art":**

### 1. Eliminating wasteful processes

We're redesigning manufacturing processes and improving efficiency. We're adding on-line treatment systems to neutralize, reduce in volume or change the nature of waste by-products. We're also using recovery techniques that let us recycle wastes back into the production process. One company, for example, is salvaging phenol, used to manufacture plastics, pharmaceuticals and other useful products.

### 2. Building secure landfills

Secure landfills have a barrier that keeps wastes from seeping out into groundwater and keeps groundwater from migrating through the landfill. Other features may include facilities for recycling liquids or a wastewater treatment unit to clean up liquids for safe disposal. Landfills—if *properly* designed, operated and monitored—are one of the best ways to dispose of many kinds of solid wastes.

### 3. Continuing industry commitment

We were finding ways to manage solid wastes long before the nation recognized the need for better waste-disposal methods. In fact, we already had much of the required waste-disposal technology and remedial strategies in place—or being developed—when Congress passed the Resource Conservation and Recovery Act of 1976, which sets forth strict waste-disposal guidelines.

### 4. Sharing knowledge and new technology

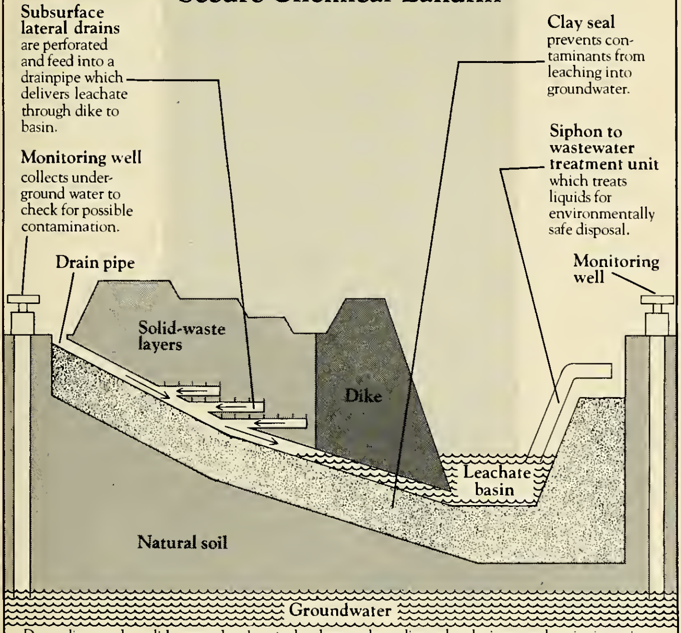
As we develop new waste-disposal techniques, we share our knowledge with industry, government and the public. In 1979, we began conducting a series of regional seminars that presented current techniques for solid-waste disposal. Individual companies may use videotapes, visual aids or other techniques to train personnel in waste-disposal methods.

### 5. Encouraging solid-waste exchanges

Sometimes one chemical company's wastes can become another company's raw material. Fluoride wastes from a phosphoric acid plant, for example, can be used by a company producing aluminum. So the chemical industry has encouraged the development of waste-exchange organizations, which develop and distribute lists of available wastes.

*For a booklet that tells more about what we're doing to protect the environment, write to: Chemical Manufacturers Association, Dept. HL-12, Box 363, Beltsville, MD 20705.*

### Secure Chemical Landfill



**Subsurface lateral drains** are perforated and feed into a drainpipe which delivers leachate through dike to basin.
**Monitoring well** collects underground water to check for possible contamination.
Drain pipe
Solid-waste layers
Dike
Natural soil
**Clay seal** prevents contaminants from leaching into groundwater.
**Siphon to wastewater treatment unit** which treats liquids for environmentally safe disposal.
Monitoring well
Leachate basin
Groundwater

Depending on the solid waste, the chemical industry selects disposal techniques such as incineration, by-product recovery, stabilization or secure landfill design to protect the environment.

**America's Chemical Industry**

The member companies of the Chemical Manufacturers Association

cowled, Rasputinlike figure imperiously swept the common tourists back from the sepulcher entrance each time a group of higher paying, candle-bearing tourists (called pilgrims) came into view, led by yet another Rasputin. This generated hostility between non-candle-bearers and candle-bearers, as well as between the various clerics, as there seemed to be an endless succession of rival sects competing for time and space, and of choirs filling the air with competing sounds, adding to the general commotion.

Looking for my colleague I found him a few yards away at the rear of the shrine, down on his hands and knees, half hidden inside a hole in the wall. As I watched, his right hand came out and groped blindly for some money in his pocket, but his other arm remained inside, stretched as if held. Once he had transferred the money back inside the hole, however, his left arm was released and my friend stood up, looking very embarrassed (he was an atheist); in his left hand he held a microscopic wooden cross, wet where it had been sprinkled with allegedly holy water by the monk who had that concession and crouched concealed inside the little cavern, waiting for his prey.

The lovely and historic streets of Old Jerusalem, crying out to be respected and loved, suddenly became unwholesome, distasteful, and alien to me, beautiful only when empty of tourists and pilgrims, clerics and commercialism. It was the same almost everywhere, from Bethlehem to Nazareth, down on the shores of Galilee and up on the summit of Mount Tabor. The tourist industry, which attracts the money that helps preserve the monuments that attract the tourists, is paving the way for the destruction of the very source of its attraction. Tourists seeking the sacred, to touch and be touched by it, desecrate it by their very eagerness and haste, just as the competing sects desecrate the sacred by their very competition and commercialization.

But then I realized that I had slipped from my role of being a tourist; I was being too academic and was consequently missing the whole point. Despite their own, not inconsiderable skepticism about the authenticity of either the sites or the stories told about them, many tourists suspend that skepticism just long enough to allow themselves to be touched. "Oh well, I might as well do it just for fun . . . here, hold my bag, dear," said one lady with a strong Midwestern accent as she stepped forward to kneel down and kiss the star above the site of the Nativity, in Bethlehem. She arose, blushing with embarrassment because she had stayed down on her knees a shade longer than required "for the fun of it." But behind the blush she was radiant, her spectacles were positively foggy, and she walked off without a word, forgetting her friend and her bag.

I saw tourists breaking their own sacred rules of touristic hygiene and drinking water from Jacob's Well, allowing some priest to sell them a piece of the true cross, standing in quiet contemplation of the stark countryside, and walking at Qumran and Masada, where man attacked man with intellectual and religious bigotry so long ago, or frolicking in a garish seaside resort suitably located near the ancient site of Sodom and Gomorrah. Even there, the shadow of Masada touches the frolic, and the experience of being totally unable to sink in the bright blue, salty water of the Dead Sea turns out to be a miracle rather than "just fun, dear."

There are ugly tourists to be sure. Some will remember only the inconveniences, the stopping and searching at every checkpoint, and they will find the Holy Land very unholy as, in a way, I did. But then I too was touched, not so much by the shrines or by the magnificent countryside that commands such a fierce attachment from all who live there, but by the glow on the face of that woman who kissed a probably phony slab of rock and by the countless others like her, who did something "just for the fun of it" and were touched because they were not really tourists at all. They were true pilgrims who brought the sacred with them, unknown to them because it was locked so deep within their being. I suspect that the quest of many a tourist, the "fun" they are really looking for, is the unlocking of that inner part of themselves. And whether it is Christmas or not, at war or at peace, and almost in spite of itself, the Holy Land still has the power to work that miracle.

# The Miracle of Intervale Avenue

*Aging Jews cling to their synagogue amid the decay of the South Bronx*

**by Jack M. Kugelmass**
**photographs by Yoav Levy**

The two men, one sipping sweet kosher wine, the other taking his regular Sabbath shot of Scotch, both nibbling on an assortment of honey, sponge, and marble cake, were engaged in the usual conversation that accompanies the kiddush—the benediction over wine that follows the Saturday morning services.

MR. ABRAHAM: I'm telling you, Moishe, if they put a cop in the building, it's more trouble than it's worth. We had a cop in our old shul [synagogue] before it closed. He used to make long-distance phone calls, put the heat up until it was 90 degrees, put the air conditioning on, and sleep on the benches using *talesim* [prayer shawls] for a cover.

MR. SACKS: Mr. Abraham, I got nothing to worry about. They aren't going to put a cop in here. And if they do, he can't put the heat up to 90 degrees because I don't have a boiler. If he wants air conditioning, he'll have to open the windows. And if he wants to sleep on these hard benches, I wouldn't deny him the *talesim* for a pillow.

The question of increased police protection for the building was the main topic of conversation on this particular Sabbath because, two days earlier, several youths had been arrested on charges of breaking and entering. They did not take much since there was little to take. Mr. Sacks's prayer shawl and prayer book were the only things missing, and these were now in police custody being held as evidence. Most of the damage resulted from petty vandalism. Some old and tattered Hebrew books had been swept off the shelves and scattered on the floor, kosher wine had been sprinkled on the carpet, and the cloth hangings separating the men's section from the women's section had been torn down.

The shul—the Intervale Jewish Center—stands in the heart of the South Bronx, a part of New York City inhabited predominantly by Puerto Ricans, interspersed with pockets of black residents. Crime, arson, and urban decay have been so widespread in this area that the 41st Precinct, in which the shul is located, was nicknamed "Fort Apache" by the police. Like all local institutions, the shul is subjected to repeated vandalism from marauding groups of youths, although it is so denuded of

*A weekly concern of the small congregation is to achieve a minyan, or quorum of ten men.*

artifacts that there is scarcely anything left to steal. The silver ornaments that decorated the Torah scrolls disappeared years ago, and a large, discolored patch indicates the space on the wall from which vandals removed the bronze memorial plaque listing the names of deceased members of the congregation. The roof, too, has suffered from numerous attempts to penetrate the building. Periodic downpours have left the building with a musty odor, rotting wood floors, peeling paint, and falling plaster. The Torahs, hidden from view inside the Holy Ark, are covered with plastic garbage bags to protect them from the rain.

Some of the decay is a consequence of the shul's declining membership and the diminishing finances of the few remaining congregants. Built in 1923, when the south and central Bronx contained more than a quarter-million Jews, the shul could then barely house the hundreds of White Russian-Jewish immigrants who competed for seats. Nearby, rows of stores catered to the culinary needs of observant Jews. Today, the once plain but solid rows of middle-class houses and apartment buildings are pockmarked by vacant, rubble-strewn lots. Dug into the ground like an exposed bunker, the shul seems to shrink from its neighbors: an abandoned six-story apartment building on one side; a garbage-strewn lot on the other.

Inside, a half dozen stairs lead down from the entrance to a main hall large enough to seat five hundred people. The dozen or so congregants who still attend services are scattered throughout this room. Some sit alone, others in small groups. A few roam about the hall, checking for needed repairs, while others busy themselves at the rear of the shul, preparing the food and wine for the kiddush.

On one side of the main hall the windows are boarded over with plywood. Two velvet Torah covers, white and purple, hang beside a large, red cloth tacked onto one of the sheets of plywood. The Torah scrolls they once contained were donated to a synagogue in Israel. These empty covers are not the only reminders of the decline of the Jewish community in the neighborhood. Covering the lectern for reading the Torah are several layers of white, orange, and red velvet, each with its own gold embroidery indicating the name of the congregation to which it once belonged. These hand-me-downs from other synagogues give the shul the quality of a survivor whose task it is to bear witness to the fate of a much larger collective. Like the artifacts, the congregants found their way to the Intervale Jewish Center after other neighborhood synagogues closed. They remember their synagogues when they were filled to capacity and were the cornerstones of a vibrant neighborhood.

In the face of this decay, Mr. Sacks's defiantly humorous remarks about having a policeman in the building reveal a justified optimism in the shul's future. Although the shul suffers from financial problems and the constant threat of vandalism, neither poses an insurmountable risk. Over the years, the most serious question the shul has faced is whether or not it can assemble the minyan—the ten adult Jewish males who constitute a quorum for ritual purposes. Despite the age and frailty of the congregants and the neighborhood's reputation, the minyan has, with

*Roguishly covering his face like a wanted man, Dave Lentin allows a photographer in his home.*

few exceptions, continued week after week, year after year. As Mr. Sacks explained to me during our first conversation, "When one person leaves or dies, someone else seems to come along to take his place. This is the miracle of Intervale Avenue."

I quickly learned that I, too, was part of the miracle. As an adult Jewish male who visited the shul on a regular basis, I became a member of the minyan. Presumably, when my study ended, someone else would come to take my place. Nor was I the only outsider to visit the shul. Besides the occasional calls by reporters there are those who have established a more enduring relationship with the congregation. One man, who commutes from Long Island to manage a local department store, attends the Sabbath minyan regularly, while another, a store owner, drops by from time to time. In addition, two groups of Jewish volunteers maintain contact with the shul, providing "care packages," outings, and other assistance to the congregants and the score of other Jews who live in the area. One of these organizations even arranged to have CBS News visit the shul and broadcast the activities the group had sponsored. Some members of the congregation relish the glamour of media exposure and enjoy having photographs to send to children and grandchildren. Almost all are receptive to outside publicity, hopeful that it will help preserve the minyan and the building in which it is housed.

The congregants, mainly elderly, are a motley group. Most are Ashkenazic Jews who emigrated from Eastern Europe in their youth. A few are black Jews, who consider themselves descendants of the union of Solomon and the Queen of Sheba. Aside from their concern for the shul and their need for religious expression, little holds them together. Most live scattered throughout the neighborhood, far from each other. Their closest ties are to friends and family who live elsewhere in the metropolitan area. Also intense are their ties to deceased spouses, parents, and sometimes siblings. Memories are one important reason they remain in the area; another is the shul and the pride taken in maintaining the minyan. In the words of one member, "When the shul goes, I go." Then, too, there is the relative comfort derived from living an accustomed life in a familiar neighborhood. When I asked one 86-year-old woman why she had never considered moving to Miami, she exclaimed: "Miami? It's not safe there. It's worse than New York!" Another woman responded with equal alarm at the thought of moving to a better neighborhood: "And now where could I go. To a neighborhood where I'll be a stranger, a strange woman ringing the bell, an old woman. They hate old people."

For such elderly people, independence and self-esteem are closely related. These are not people who have been abandoned by their children. On the contrary, they have chosen to live independently, among their peers. One 82-year-old woman, who acts as secretary for the shul, explained why she would not move into her daughter's suburban home, despite repeated invitations to do so:

> I like to be like a guest. I'll never forget a few years ago, unexpectedly visiting my daughter. I didn't tell her I was coming. But when my grandson saw me coming, he didn't

*Elsie Miroff's seamstress shop gives her contact with the street life she enjoys.*

run toward me. He ran upstairs to tell his sisters, "Guess who's coming. Granma's coming!" You see, if I lived there, I wouldn't hear all this, would I?

What is most striking about these people is their ability to lead active lives in an area where few New Yorkers care to venture, let alone live. Their determination is all the more remarkable considering their advanced age and physical vulnerability. The neighborhood, like their age, sets the framework within which they live, but it does not determine, in a deeper sense, the quality of their lives. For most of them, the decay of the South Bronx is an adversary much like death. It is inevitable. One cannot flee from it, yet some form of resistance is necessary. When an aged person succumbs to decay, he is at death's threshold. These people are very much alive.

Dave Lentin tells me that he is a wanted man. He shies away from television cameras and resents the intrusion of his space by reporters. Dave is a killer. As caretaker of the shul, it is his responsibility to poison the rats and dispose of their bodies. Dave hates rats. He also hates to kill.

Dave is sixty-nine years old. His boyish grin and verbal antics are a mask, suggesting the trickster nature of his character. "People think I'm nuts," he says, "but that's just to fool them. Like a cat plays with a mouse. The cat acts like he's playing. When he's ready, he pounces." Dave's antics provide a humorous counterpoint to the seriousness of the other men. He typically responds to a Yiddish greeting with a Spanish one. Or he pretends not to know the difference between Yiddish and Spanish, rabbi and priest, Jew and non-Jew. He loves to mimic the other men. When he engages in the customary handshaking after performing part of the Sabbath ritual, he carries it to an extreme by pumping each and every hand in the shul. He often replaces the traditional Hebrew benedictions with homonymous English words or phrases. No one seems to mind.

Dave's trade is sign painting. His labor is everywhere in evidence, both outside and inside the shul. Some of his signs are multicolored paintings. Others are simple, graffitilike words or phrases in Hebrew or English. Typical of his work are the two hand-lettered signs on the inside of the twin doors that close the main room from the entrance hallway: *am yisroel khay* ("Let the people of Israel live!") and "Thank you—Come Again." Dave often talks about his ideas for covering up the broken plaster and the peeling paint. One is to paint the ceiling with a Biblical scene of Adam and Eve, "maybe with, maybe without fig leaves. I haven't decided yet."

Dave also works as a caretaker at a local senior citizens' center, where his lettering decorates the cover of the minutes book. He invariably sneaks a Hebrew word in with the Spanish, explaining to the Spanish-speaking members of the center that the letter ש ("shin") is not a letter at all, but a picture of three men in a boat. In exchange for his work, Dave receives a small salary. He also accumulates Spanish benedictions, which he dispenses like weapons of self-defense to disarm and charm.

Despite his preoccupation with Hebrew lettering, Dave's

*As surrogate mother to Betty (second from left), Mrs. Miroff (right) has earned her neighbors' respect.*

knowledge of Hebrew is not very extensive. His own religious training did not begin until his mother died twelve years ago. Dave was initially unable to cope with the loss. Eventually, he pulled himself together, partly through the help of a local rabbi who taught him how to recite the kaddish, the Jewish prayer for the dead. Dave learned the words in a few days by repeating them over and over again. He continues to repeat the words whenever he can. When he sees a dead animal or tree, he says kaddish. As Dave explains: "Trees are part of God's universe. Look at their branches. They point upward to God, not down. Down there are rats. I won't say kaddish for them. They belong to the devil. Let him say kaddish for them!"

Although it is customary to say kaddish for one year following the death of a loved one, Dave continues to recite the prayer at Sabbath services each week. He pays scant attention to the rest of the service, roaming about the shul and joking with the people. But when it is time to say kaddish, he races to the front of the hall and recites the prayer, as he says, "from the heart." This is one of the few activities Dave performs with a completely straight face; the one time he joins the congregation as an active member, contributing to the service and deriving satisfaction from it.

In a congregation this small, a person's presence is itself a contribution. Still, Dave is tolerated not simply because he is needed for the minyan. He also represents something. The other men encourage him to say kaddish, as if his prayer stood for the mourning of the congregation as a whole. In a sense, Dave is an archetypal kaddish, the male child whose prayer protects his parents in the other world. His prayer has ceased being the prayer of one son for a deceased mother. It is the prayer of all children for all parents. Some members of the congregation have survived their own children. Others are uncertain of their children's religious devotion. For all of them, Dave is a kaddish. He is the caretaker of the shul in this world, the caretaker of the congregants in the next world.

Almost all the congregants have exercised some amount of choice in remaining in the neighborhood. Dave, who does not consider the neighborhood particularly dangerous, is one of the few who probably has no other option. Moishe Sacks, who does consider the neighborhood dangerous, has many other options. He is politically astute and has many contacts among city and private Jewish agencies. His children are accomplished professionally and could help him settle elsewhere. Moreover, he is employed as a baker and could be considered relatively well-to-do.

Nevertheless, Mr. Sacks, like the others, is tied to the area. Although he tried to settle in Israel seven years ago, he kept his apartment in the South Bronx in case he returned. And he did return because he could not find a suitable job in Israel, although he even offered to pay a baker to let him work. In the South Bronx, he works a sixteen-hour shift each weekday, and his labor and organizational skills keep both a bakery and a shul afloat.

*The synagogue reflects the poverty of the small congregation and the ravages of vandalism.*

Sacks is a defiant man, who refuses to retire although he is well into his seventies and has a serious heart condition. And he resists closing the shul despite repeated vandalism. The police have suggested that the congregation find safer quarters in which to pray, but Sacks adamantly refuses to abandon the building: "If we give in to vandalism and go elsewhere, we won't be any safer. If they chase us out, no one is safe anywhere."

Nevertheless, vandalism and the deteriorating neighborhood have been getting the better of the shul. Membership has declined, and functionaries, both religious and secular, have left. Because of the age of the congregation, weddings and bar mitzvahs are no longer celebrated. Benefactors are few. Sacks has taken on a variety of roles in order to provide a full range of services to the congregants. He actively solicits and welcomes new members, takes an interest in their welfare, and lends a hand to those who need help. Although he lacks formal religious training, he has become the unofficial rabbi of the shul. He is the acting president as well as the caterer and the social director. Even the operating budget of the shul comes from his own pocket. The minyan survives because of the combined efforts of many people. The shul survives because of Mr. Sacks. The congregants know this and are extremely respectful toward him. He is equally respectful toward them. He enjoys the positive impact he has on other people. "I'll admit it quite frankly," he says in explanation of why he stays. "Here I'm a big fish in a small pond. It's better than being a big fish in the ocean."

As capable as Sacks is in presiding over a congregation of diverse people whose roots in the shul are not very deep, he is equally adept at gaining the confidence of people from outside the shul. The bakery is a neighborhood institution where those who are hungry and without money can eat. Sacks makes certain that leftovers are saved and distributed to derelicts and others who are down on their luck. In this way he can rely upon a network of friends and neighbors for protection. He maintains good relations with members of the police department; some off-duty officers regularly escort him to work for the midnight shift. Even local youths consider him to be a confidant and an intermediary with the police.

The Jews in the South Bronx do not live in a ghetto within a ghetto. They are dispersed throughout the neighborhood. They tend to be the only Jewish person in their building or on their block. They are sociable human beings. They understand people, and they have learned how to live apart from their families and other close friends. These people are not survivors merely by accident. Members of the congregation know how to establish bonds of obligation within the neighborhood. One woman collects all the leftover food from her senior citizens' center and distributes it on her block. Others use charm or friendliness as a way of reducing the dangerous effects of anonymity. They greet and expect at least a grudging "good day" from passers-by, and they talk to everyone, old or young. But few are as resourceful as Elsie Miroff in establishing her position in the neighborhood.

Mrs. Miroff is eighty-two years old. She suffers from

*The principal organizer of the synagogue is Moishe Sacks, who is a baker by profession.*

a failing voice, shortness of breath, and hypertension. The trip to shul is an effort for her. She is not always well enough to walk the dozen or more blocks, and she fears for her safety the moment she leaves the narrow confines of her immediate neighborhood. Despite her frailty, she takes charge of bringing wine for kiddush and coffee for Sunday brunch. Like Mr. Sacks, Mrs. Miroff commands a good deal of respect from the other congregants.

Mrs. Miroff guards her independence fiercely. She maintains a seamstress shop in a dimly lit, narrow storefront next door to her apartment. The small room is cluttered with clothing that people have brought to be repaired. Most of the clothes are never claimed by their owners. Mrs. Miroff sits at her sewing machine in the front of the shop and occasionally looks out the small window through a metal grate that a neighbor fashioned for her. Her shop gives her an important point of contact with her neighbors. It is well heated in winter and cool in the summer. People on the street are welcome to drop by to talk and to warm up or cool off as the case may be. In addition, Mrs. Miroff has some half dozen chairs stashed away, which she lends to various men who sit outside the shop, a choice location because it is next door to an illicit numbers parlor.

Without her shop, Mrs. Miroff would feel trapped in her apartment, shut off from the street life that she enjoys so much. Rent is cheap, and her Social Security checks cover the cost of the apartment and the shop. She could not afford to maintain both anywhere else in the city. Mrs. Miroff sees herself as a giver, not a taker. It is an important source of pride:

> This is it. From what I make, I got enough for wine for kiddush, for a donation. This is it. Give a few dollars to who I want to give. This is not a luxury life, but it's a life. And not to take by anybody anything. Is that the best? You agree with me?

How could I argue otherwise?

There is another reason Mrs. Miroff prefers to remain in the neighborhood. She is very attached to her present apartment, where she has lived for forty-two years. She raised her family in it, worked as a seamstress in it. And her husband died in it. Her memories are so closely connected to the apartment that she is unwilling to part with it. She also feels comfortable there. Despite the decline of the South Bronx over the past fifteen years, it is home. Still, her sense of security is not a passive outgrowth of long-term residence, but a direct result of an active pursuit on her part.

Betty is a constant visitor to Mrs. Miroff's shop. Betty is black. She is forty years old and retarded. The relationship between Mrs. Miroff and Betty goes back seventeen years, when Betty's family first moved into the building and Mrs. Miroff's husband died. The two women have been close companions ever since. Just over a year ago, Betty's mother abandoned her and left her in Mrs. Miroff's care. The neighbors refer to Mrs. Miroff as the "white nigger" because of her role as Betty's surrogate mother.

Betty needs guidance and companionship. Beyond the confines of her immediate home neighborhood, Mrs. Miroff needs a protector. Betty accompanies Mrs. Miroff to shul and sits with her during the services, patiently waiting for the kiddush cake or Sunday brunch. In a way, Betty fits in among the congregants. Her hand-me-down clothes from Mrs. Miroff's shop are no different from the clothes worn by other members of the congregation. The decay of her body, most visible in her toothless mouth and obesity, makes her all the more indistinguishable from many elderly Jews.

Mrs. Miroff refers to Betty as "mine bodyguard," and the members of the shul accept Betty as her appendage. Although Betty could not really protect Mrs. Miroff in the event of an assault, Mrs. Miroff feels safer walking beside her. Being seen next to "a black face," as she puts it, lends her respectability in the neighborhood. And her feeling of security appears to be justified. By looking after Betty she has gained the respect and admiration of her neighbors.

For Mr. Sacks and Mrs. Miroff, and for many others who participate in the services, the shul is a focal point of their lives. For some congregants, it is the only reason they remain in the neighborhood. Each action on behalf of the shul is meaningful and gives status and self-esteem to the person who performs it. From serving the food to reading the Torah, each task seems important.

The shul is a source of pride, a concrete symbol of defiance and perseverance that closely resembles the people it serves as a house of worship. It is an aging, decaying structure whose "looks," if they ever existed, have long since disappeared. Its shabby, drab exterior resembles the tattered clothes of the congregants and the plastic shopping bags they carry at their sides. And yet, the shul is still standing and in regular use. It has outlived every other shul in the area, most of which were wealthier and more beautiful. Above all, it continues to get, week after week, the minyan of ten men. As long as the minyan is intact, its individual components are secure.

Although the benedictions over the Torah and the kaddish cannot be recited without the minyan, most of the rest of the service remains the same. Still, the minyan is of vital concern. On the rare occasion when a tenth man is unavailable, the minyan is considered complete with only nine, since (according to Mr. Sacks) God stands in for the tenth man. The cantor, however, opposes accepting nine men as a properly constituted minyan. One Sabbath, during kiddush, I asked Sacks how there could be this disagreement.

"You see," he explained,

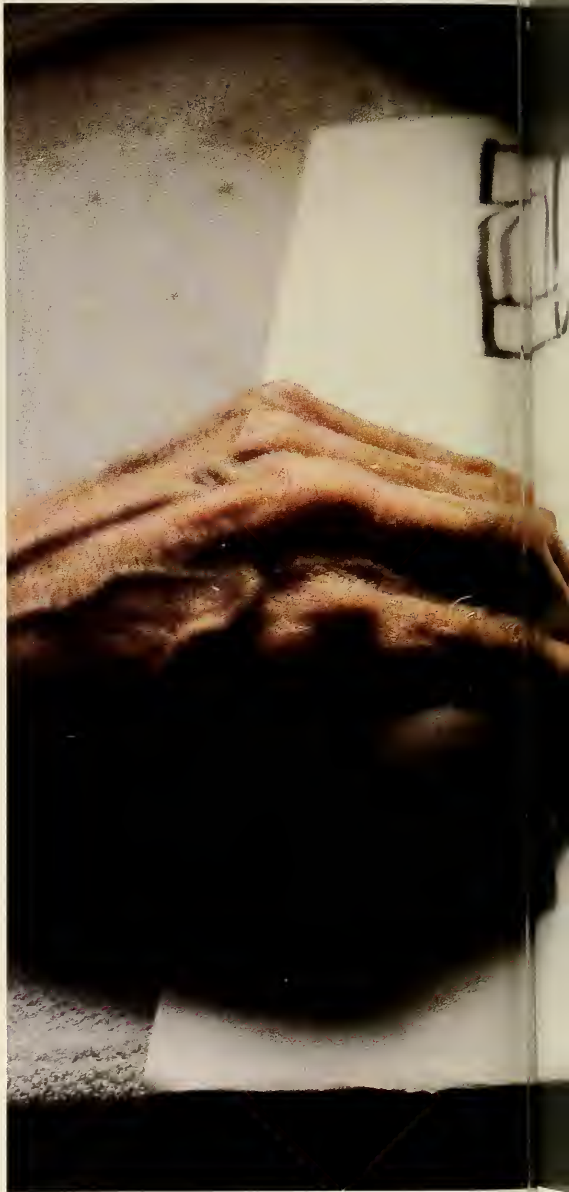
> when God told Abraham that he would destroy Sodom unless fifty righteous people could be found there, Abraham asked God whether he would do it if there were only forty-five righteous people. God said he would not. Abraham got braver and asked whether he would do it if there were forty righteous people. God said no. Thirty? No. Finally Abraham asked whether ten righteous men would save Sodom. Again, God replied that he would not destroy Sodom if ten righteous men could be found. At that point Abraham knew that he could not ask for anything more, and he walked away.

"So," I replied, "that explains why ten are needed for the minyan. What about nine? How do you arrive at the figure nine?"

"Well," Sacks responded,

> we don't know exactly. But Rashi, the great commentator, says that at the time of the flood there were only eight righteous people—Noah, his wife, their three sons, and their wives. There were eight righteous people, and God destroyed the world. So we know that eight righteous people are not enough to save the world. But nine we don't know. So if we don't know, we can hope that nine is enough.

As long as the minyan exists, some semblance of the world that Mr. Sacks and other members of the shul knew and loved survives. By keeping the shul alive, they are indeed staving off the destruction of a world.



The Sabbath is not always strictly observed at the Intervale Jewish Center. Sometimes repairs must be made or extra nails hammered into place to buttress the shul against vandals. One Sabbath, Moishe Sacks and Sam Davis stood outside and examined the metal-covered door of an unused entrance that had been partially damaged the day before. I stood there too, contemplating the motives for the damage and listening to the conversation between the two men.

"Mr. Davis, did you bring your hammer?"

"Sure I did. When a soldier goes to war, he brings his gun. My hammer is my gun. This is a war!"

Mr. Sacks liked the metaphor. He thought for a moment, smiled, and then commented: "You're right. This is a war. Your hammer is your gun, and my [prayer] books are my gun. And his . . . [he pointed to me and hesitated, because I did not have my tape recorder with me that day] whatever he has, that's his gun."

I too was pleased with the metaphor. I smiled and decided to remember the conversation. ☐

# Needs of Weeds

*Prodigious propagators and able opportunists, weeds prepare the way for longer-lived plants*

**by John C. Kricher**

America is often referred to as the "land of opportunity." Waves of human immigrants from many countries have come seeking a prosperous life in the New World. *Homo sapiens*, however, is far from the only species to succeed in colonizing America. Dandelions, crabgrass, Queen Anne's lace, lamb's-quarters, sheep sorrel, and even bluegrass are but a small sample of a large constellation of alien plant species that have been assimilated into the ecology of North America. Having successfully invaded an area in which they did not evolve, these immigrant species, commonly referred to as weeds, share their North American habitats with such native weed species as common ragweed, asters, and goldenrod. Weeds may be the scourge of gardens and the cause of allergies, but their role as colonizers is vital to the health of ecosystems. An examination of the needs of weeds and their awesome array of adaptations provides a substantial lesson in the workings of ecology and evolution.

Weeds are plants whose populations grow wholly or predominantly in areas that have been markedly disturbed. Lawns, roadsides, gardens, gaps that appear in a tropical forest after a blowdown, and recently abandoned agricultural fields are ideal habitats. The key words in the above definition are "markedly disturbed." Mature forests pose no threat to ragweed sufferers since ragweed, like other weeds, cannot grow in deep forest shade. A newly disturbed area, however, flooded with sunlight and devoid of competitors, provides optimum conditions for any organisms that can, first, find the area (that is, disperse well) and, second, grow and reproduce with vigor. Whole ecological communities are reshuffled and the intense game of ecological competition begins again in these temporary ecological vacuums, which offer opportunities for invasion by enterprising species. Weeds are the champion biological opportunists.

In a field that has been plowed under, abandoned, and allowed to remain fallow, a sequence of events occurs that is known collectively as ecological succession. Following a disturbance, such as plowing, different plant communities occupy an area in a characteristic sequence. In time, the rate of succession slows down until most species present are self-replicating, and whatever constitutes the normal type of ecosystem for that particular geographical area is reestablished. In the Northeast, a forest will eventually develop. Weeds are always the initiators of this process, the first colonizers. Why, in a bare, plowed field, don't oaks, maples, and hickories simply populate the area immediately? Such an event never happens. Trees, which will be the major species at the cessation of the succession, only begin growing fifteen to twenty years after the field is abandoned. Prior to the appearance of trees, the field is the exclusive realm of herbaceous and woody weed species—the ragweeds, dandelions, fleabanes, asters, goldenrods, poison ivy, and grasses.

A comparison of a white oak tree with a common dandelion will make clear why trees cannot be the first colonizers. To colonize an area, a species must first insure that its propagules arrive there. Good dispersal powers are essential. Since wind is more pronounced in open areas, species that exploit wind for dispersal

are at an advantage in finding such sites. Acorns, the seeds of oak trees, are relatively heavy and must be transported by animals such as blue jays and gray squirrels. An acorn could not reach a disturbed site easily. By contrast, dandelion seeds, like seeds of virtually all weed species, are wind dispersed. The tiny seeds weigh almost nothing, and helped by their delicate "parachutes," they drift like dust specks. People often aid in dandelion dispersal by blowing the flower heads for amusement. Milkweed and thistle are other well-known examples of wind-dispersed weeds.

Weed seeds not only travel easily; they are also plentiful. Weeds, many of which are annuals, devote huge amounts of energy to reproduction. Ecologists Sandra Jo Newell and Elliot Tramer of the University of Toledo found, for example, that common lamb's-quarters, an abundant annual, produces an average of 4,820 seeds per plant. Some individual plants produce as many as 50,000 seeds. Measured in terms of weight, the average common lamb's-quarters plant devotes fully 25 percent of its energy toward reproduction. To appreciate the magnitude of this effort, we need only compare these figures with those obtained by Newell and Tramer for cut-leaved toothwort, a common forest wildflower. An inhabitant of stable woodlands rather than disturbed fields, the toothwort produces an average of 24 seeds per plant. The highest seed count for a given plant is 42; the overall reproductive effort by weight is only one percent.

Unlike trees, weeds are adapted to reproduce prodigiously rather than to persist for long periods. One indication of this is the large numbers of annual and biennial species that have evolved. I studied weeds in two fields in New Jersey: one was only two years post-abandonment; the other had been unused for thirty years. The two-year-old field consisted entirely of herbaceous species, of which fully 47 percent were either annuals or biennials. The thirty-year-old field, in contrast, consisted largely of perennial grasses, shrubs, and trees. Of the herbaceous species in the thirty-year-old field, only 21 percent were annuals or biennials. The more persistent, rather than the rapidly reproducing, species were coming to dominate the ecosystem as it aged.

Each weed seed is a miniature time bomb, able to remain dormant almost indefinitely but set to explode into germination when the time is right. Many cases have been documented of the successful germination of weed seeds found in anthropological sites hundreds of years old (see "Long-lived Seeds," *Natural History*, February 1979). The seeds wait, in a state of suspended animation, for the inevitable fire, hurricane, or ax that will destroy the forest and provide the sort of environment in which they thrive. Only then will they quickly germinate and live out their short lives making more seeds. Acorns, in contrast to weed seeds, lack longevity. Most will be eaten or succumb to fungal rot within a year or two after falling from the parent tree.

An understanding of the herculean reproductive powers of weeds forces us to redirect the previous question about why oaks, maples, and hickories do not populate disturbed areas immediately. Indeed, considering the reproductive abilities of weeds, we must ask, Why do tree species ever appear at all? The answer to this question is found in the adage "You can't have it all ways." In maximizing their genetic energies toward high dispersal and reproductive powers, weeds have little energy left to cope with potential competitors. As a further complication, weeds must also devote much of their energies to maintaining themselves in physically rigorous environments. Disturbed areas are often windy, sunbaked, and subject to intense erosion. Weeds are adapted for pioneering, not for persisting.

*Aster pilosus* is a pioneering plant found in many abandoned fields and along roadsides. David L. Peterson and Fakhri A. Bazzaz of the University of Illinois studied the life cycle of this common aster and learned that the plant makes "choices" relative to how it reproduces. An aster germinated in spring may flower late in the summer and set seed. Or it may, in response to competition for nutrients with other plants such as ragweed, not flower but assume a prostrate dandelionlike rosette form and pass the winter hugging the ground. The rosette is not dormant and actively photosynthesizes during the cold months. The following spring, if nutrients are sufficient, the aster will "bolt" and grow rapidly, flowering and setting seed early. Finally, in favorable environments, asters frequently also spread by reproducing vegetatively. The reproductive characteristics of the aster are clearly directed toward opportunism. As succession proceeds in an area, asters cannot compete with other plants for prolonged time periods. They must seize their moment, reproduce, and then perish.

Fakhri Bazzaz also studied common ragweed and learned of the physiological adaptations that enable it to cope with life in open fields. Ragweed can photosynthesize rapidly, adding as much as 14 grams dry weight per meter squared per day during favorable periods. The species manages this through a genetic ability to tolerate, and indeed to thrive on, very high light intensities that would inhibit photosynthesis in most other plants. In addition, ragweed photosynthesizes over a very wide range of temperatures and under high concentrations of carbon dioxide, conditions characteristic of open areas. Finally, ragweed demonstrates a phenomenal ability to recover rapidly from drought. In a word, ragweed is physiologically tough. It has, however, apparently paid an evolutionary price for its skills. Once it has become established in a field, its prevalence begins to decline rapidly. A first-year field may contain a dense stand of ragweed plants, each in excess of three feet tall. The second summer, however, the ragweed plants are stunted and may be only about six inches tall; all are destined to disappear entirely by the third summer. Catherine Keever studied a similar stunting phenomenon with horseweed on abandoned fields in North Carolina. She learned that the stunting is caused both by the competitive effect of other species, such as the asters, and by the decomposition products of horseweed's own roots—horseweed actually poisons itself! Evidence indicates a similar situation for ragweed.

These observations have one prac-

*Apple tree in abandoned, weed-dominated orchard*

tical application: spraying tall ragweed clumps with herbicide is probably not a good idea. Doing so only "sets back" the succession by reestablishing the disturbed condition and insures that a new and vigorous crop of ragweed will invade the following year. Leaving the ragweed alone, on the other hand, will, within a year, lead to its probable disappearance through self-destruction and loss to competing species.

The significance of the ragweed example lies in its emphasis upon ragweed's range of adaptations, which allows it to exploit environments that would be insurmountably severe for most species. By merely being there, ragweed dramatically alters the ecosystem, reducing its physical severity. Ragweed stands provide shade, retard wind flow over the ground surface, and produce organic material, which, in the form of roots, helps stabilize the soil and, in the form of decay products, enriches the soil organically. Other species, unable to invade initially because of the physical rigorousness of the environment, may now become established. Thus perennial grasses, with their more extensive root systems and greater shade tolerance, can now thrive, and they do so at the expense of the pioneering ragweed. Whatever evolutionary talents ragweed has developed for colonization do not extend to persistence. Once environmental severity has been reduced, ragweed is unable to compete with other, less physically tolerant species for the limited space afforded in the field.

Nothing illustrates the evolutionary trade-off of adaptability to a rigorous environment at the cost of competitive ability better than work done on several weed species by Sheila C.A. Cook and coworkers at the University of

Liverpool. Cook and her team of researchers studied two grass species and one herb that grow in North Wales on soils heavily contaminated from a zinc/lead mine. The grasses, *Agrostis tenuis* and *Anthoxanthum odoratum*, and the herb, *Plantago lanceolata* (English plantain), also grow abundantly on noncontaminated soils. Plants from contaminated and noncontaminated areas were grown together in noncontaminated soil to test the effects of competition. (Of course, a *Plantago* from a noncontaminated area could not grow in contaminated soil since it lacked the genetic ability to deal with the presence of the heavy metals.) In all cases, plants from noncontaminated soils easily outcompeted those from the zinc/lead soils. A *Plantago* from the area around the mine could not coexist with one from a noncontaminated area. In adapting to the extremely rigorous zinc/lead soil environment, the plant populations that succeeded had sacrificed some of their competitive abilities. They were really fugitive races existing only by virtue of their tolerance for an environment lethal to virtually all other species.

A similar situation exists in northern California as a result of the peculiar nature of the soil there. Soils derived from rocks high in magnesium iron silicate are termed serpentine soils. With poor supplies of essential nutrients and high concentrations of such potentially lethal heavy metals as nickel and chromium, the patchily distributed serpentine soils present colonizing plant species with severe environments. Nonetheless, serpentine races of weeds such as *Plantago erecta*, a common plantain species, occur regularly. When grown together with nonserpentine races of the same species in nonserpentine soil, serpentine races simply cannot compete. Apparently, the genetic reorganization required to produce a phenotype capable of living and reproducing in a harsh environment results in a dramatic change in the total pattern of development. Characteristics such as shade tolerance are no longer selected for since most disturbed environments are sunny and probably poorly vegetated. Indeed, the grasses that evolved tolerance to the zinc/lead mine soils were shorter than the plants from uncontaminated soils, which would put the tolerant plants at a disadvantage if they invaded uncontaminated areas. They would be overtopped and shaded out by their nontolerant relatives.

Some researchers believe that the genetic reorganization of developmental patterns required for adaptation to severe environments is of sufficient complexity to result in speciation. The zinc/lead mine soil grasses have evolved flowering times different from those of the nontolerant races. Also, the tolerant races are much more self-fertile than nontolerant populations. Both of these characteristics suggest the rapid evolution of reproductive isolation between tolerant and nontolerant populations.

For all their abilities to colonize harsh environments, weeds lack the competitive strengths to persist. Oaks, of course, lack the weeds' abilities to survive in extreme situations. Should an acorn actually sprout in a parched, sunny field it could indeed be "outcompeted" by the ragweed. However, when an acorn finds its way into a more moderate environment, its developmental pattern maximizes its chances of a long life. The oak tree devotes the lion's share of its energy to strengthening itself through the manufacture of extensive roots and branches, a thick, strong trunk, and myriads of leaves. Energy is used not merely to build but also to repair tissue. Chemicals such as tannins are produced, and these byproducts of the oak's biochemistry aid in discouraging insect attacks on its leaves. In addition, although the oak devotes far less of its energy toward reproduction than does lamb's-quarters, it has many more years to keep trying. Acorns may be heavy and short-lived, but only two need be successful for the population of oaks to remain unchanged.

Darwin, in the *Origin of Species*, recognized that more than one "strategy" exists for evolutionary success. Weeds and trees are good examples of ecological opposites. The weed puts

*Field of butterfly weeds and other wildflowers* most of its efforts into reproduction and dispersal. Each seed has a poor survival chance, so survival depends on large numbers being dispersed. The tree puts much of its energy into its own growth and competitive ability. Reproduction is moderate but continues over a long life span. Each acorn has more energy to begin with than does any weed seed and each acorn consequently has a better chance of survival.

The life history characteristics of weed species largely account for the abundant representation of European weed species in North America. Ecologists now characterize as "fugitive species" those weeds that succeed by skipping from place to place, taking advantage of temporary ecological disturbance. Considering the abilities weeds possess for dispersal and colonization, we can understand why aggressive European species have succeeded in American fields. Conversely, a lack of these abilities acts as a barrier to range expansion. European plants characteristic of undisturbed ecosystems, such as a forest, are still mostly in Europe. They lack the adaptations for nomadism found in the weeds. In addition, even if a European forest species could invade North America, it would face enormous competition from well-adapted native species. An undisturbed, ecologically balanced forest is a more difficult system to penetrate than, for instance, a recently burned area. Forests are saturated with species, whereas fields, burns, or hurricane blowdowns offer opportunities for the fugitives.

To illustrate this point, I calculated the percentage of introduced, or alien, species present in the 2-year-old field, the 30-year-old field, and a 200+-year-old oak-hickory forest I studied in New Jersey. In the 2-year-old field, 51 percent of the plant species were alien as opposed to 13 percent in the 30-year-old field and only 6 percent in the forest.

The presence of an abundant weed flora, native and introduced, provides ample evidence for the assertion that forested ecosystems in North America have been subjected to frequent disturbances throughout history. The great hurricane of September 21, 1938, destroyed millions of square miles of New England's forests but was a real vitamin shot for weeds. It is important to realize that as weeds invade a newly disturbed area, they perform a vital function relative to the welfare of the trees that will succeed them. Weeds are the stabilizers, the ecological Red Cross that moves in and prevents further damage while simultaneously aiding in the recovery process. Throughout the northern and western United States, for example, there is a plant called fireweed (*Epilobium angustifolium*). Fireweed's name is descriptive since its wind-blown seeds move in following a forest fire, and the plant then prospers until shaded out by aspens and, eventually, spruces. Its root system aids greatly in minimizing erosion on the burned area as well as adding valuable organic matter to the damaged soil.

An even more dramatic example is the role of the pin cherry (*Prunus pennsylvanica*) in the recovery of northern hardwood forests following disturbance. Although not herbaceous, the pin cherry is really a woody weed since it requires bright sun and open space, grows rapidly, disperses well, and is easily outcompeted by shade-tolerant tree species. P.L. Marks of Cornell University and F.H. Bormann of Yale University studied the pin cherry as it grew in an experimental area in the Hubbard-Brook Forest in New Hampshire. Following clear-cutting, the soil experienced very heavy mineral loss as a result of erosion. The pin cherry was robust enough to populate the disturbed site, and within five years all mineral levels in the soil had significantly increased. The tree had stabilized and aided the recovery of the area's depleted soils, thereby insuring the future reoccupation of the site by hardwood forest.

Weeds are magnificent organisms. They testify to the ability of life to cope with all environments. Weeds, in the most literal sense, "make hay while the sun shines." □

# Salamander Invasion of the Tropics

*No longer restricted to aquatic habitats, lungless salamanders dispersed southward and achieved their greatest diversity*

**by James Hanken, James F. Lynch, and David B. Wake**

What is evolutionary success? Perhaps the most obvious example is an adaptive radiation: the divergence of members of a single lineage into a number of different ecological niches or adaptive roles. This divergence can involve changes of morphology, physiology, ecology, and behavior. By investigating adaptive radiations, we can learn the causes and limitations of evolutionary change.

In many ways, salamanders might seem unlikely subjects for the study of adaptive radiation. As is typical of most amphibians, salamanders must maintain a moist skin and are frequently restricted to aquatic sites in or near ponds, streams, and seepages or under moist logs or leaf litter in humid forests. Because salamanders are ectothermic (cold-blooded), their energetic needs are slight—usually only a fraction of those of birds and mammals. They can feed infrequently and remain inactive for long periods; this, plus their usually small size, makes them inconspicuous. For these reasons, some biologists have dismissed them as rare and of little ecological significance.

Despite their apparent low profile, in many habitats salamanders are the most abundant vertebrates. For example, salamanders in a New Hampshire forest were found to exceed birds and mammals in both numbers and biomass. Further, salamanders display a variety of body shapes and sizes, ranging from inch-long species to an Asian genus whose members attain lengths of five feet. Some salamanders are fully aquatic, others are partly so, and many are fully terrestrial. Most species have well-developed legs and feet, but some groups have tiny limbs, and others lack hind limbs entirely. Some salamanders are subterranean, while others spend their entire lives far above the ground in the canopy of tropical forests.

*One of many lungless salamanders of Central America is* Bolitoglossa mexicana, *native to Belize. Geologic events that fragmented populations helped to create a diversity of salamander species in this region.*

Reymond A. Mendez

The approximately 325 species of living salamanders are divided among nine families. However, more than 200 species belong to one family, the Plethodontidae, or lungless salamanders, and about 150 of these, or nearly half of all salamanders, are members of one subgroup, the tribe Bolitoglossini, or, literally translated from Greek, the "mushroom-tongued" salamanders. Salamanders as a group arose in the Northern Hemisphere, and virtually all living nonbolitoglossine salamanders are confined to the north temperate portions of Asia, Europe, and North America. In contrast, all but about a dozen bolitoglossines live at tropical latitudes in Middle and South America. How can we account for this successful invasion of the tropics?

The earliest lungless salamanders were descendants of stream-dwelling salamanders of the ancient Appalachian highlands of eastern North America. The most primitive living lungless salamanders are still found in stream habitats in the Appalachians where they maintain a 100-million-year-old life history pattern. Semiaquatic adults mate and deposit eggs at streamside. Carnivorous aquatic larvae that emerge from these eggs later metamorphose into terrestrially adapted adults that leave the water. This reproductive pattern, although typical of many other amphibians, constrains ecological and evolutionary diversification. Most important is the restriction of such amphibians to areas where aquatic breeding habitat is at least periodically available. Dependence on aquatic breeding sites also limits the ability of amphibians to disperse through areas without free surface water.

Exceptions to this life history pattern are rare in most salamander families. One alternative is demonstrated by a few species of the European genus *Salamandra*, in which females do not deposit eggs, but instead retain them in the oviduct where development proceeds. Young emerge either as well-developed aquatic larvae or fully metamorphosed terrestrial salamanders.

Many lungless salamanders, including all bolitoglossines, have evolved a different means of eliminating the restrictive aquatic larval stage. These salamanders retain the primitive pattern of laying eggs, but the eggs are deposited in moist, protected terrestrial sites where the female broods them for a long period (up to eight months in some species). At hatching, a fully functional salamander emerges, having achieved complete independence from aquatic habitats.

With this fully terrestrial reproductive mode, ancestral lungless salamanders dispersed across the humid temperate forests that covered most of North America during late Mesozoic and early Cenozoic times, ultimately extending west to the Pacific coast and south into the New World tropics. Subsequent episodes of mountain building and climatic change caused much of the temperate forest to disappear from the western half of North

America in favor of more arid habitats, eliminating lungless salamanders from virtually all of the mid-continental region and northern Mexico.

Today, isolated survivors of these events give us some idea of the enormous and nearly continuous distribution that lungless salamanders must have enjoyed in the past. Relict species still may be found in pockets of favorable humid habitat in New Mexico, Oklahoma, Texas, and Arkansas, while in California's Mojave Desert, several distinctive species have recently been discovered leading precarious lives around tiny springs and seepages in otherwise uninhabitable mountains. Most startling is the present distribution of the genus *Hydromantes,* one of the two genera of nontropical bolitoglossines. The western North American ancestors of *Hydromantes* dispersed into Asia via the Bering land bridge across the northern Pacific Ocean and extended their range to the west and south until they reached the Mediterranean region. Today, we find two of the five species of *Hydromantes* inhabiting caves and crevices in limestone areas of northern Italy, southern France, and the island of Sardinia, while the remaining three species are restricted to the mountains of central and northern California.

A great expanse of inhospitable arid country at present separates the lungless salamanders of temperate North America from those of the tropics. The northernmost members of the tropical assemblage include several generalized species of the genera *Pseudoeurycea* and *Chiropterotriton* that live at high elevations in Mexico's northern mountains. In morphology and ecology, these animals resemble the presumed ancestors of all tropical salamanders. These ancestral forms continued their southward invasion via mountainous dispersal routes, leaving descendants throughout all of Middle America and much of South America as far as Bolivia.

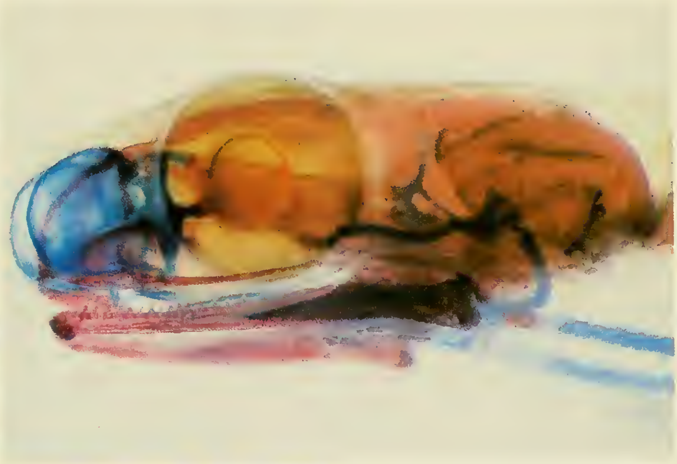
The adaptive radiation of salamanders in the tropics has produced more than 150 known species assigned to nine distinct genera. As many as sixteen species may inhabit a single tropical mountain. Salamanders in the tropics are perhaps most abundant in mountainous areas, but they also are well represented at intermediate and low elevations, with the proportion of lowland species increasing southward.

James Hanken

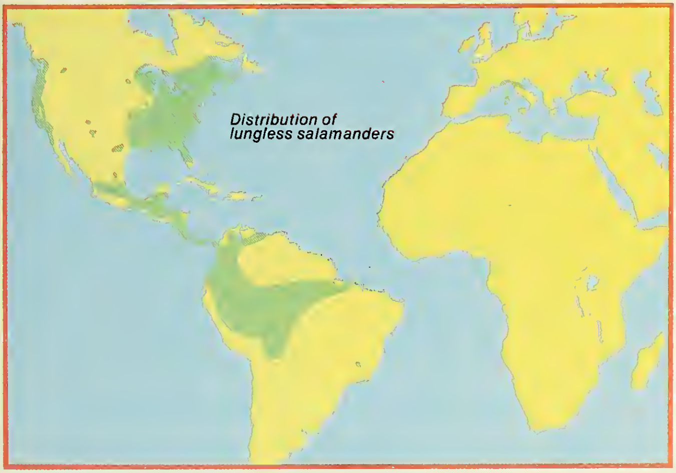
In southern Mexico and Guatemala more than 40 percent of the species are found, at least in part, below 5,000 feet and 14 percent occur below 1,500 feet. Farther south in Costa Rica, Panama, and northwestern South America, more than 85 percent of the species occur below 5,000 feet, and fully a third of the species live below 1,500 feet.

This information will help dispel the belief that tropical salamanders are restricted to high, mountainous areas with climates and habitats similar to cool, temperate forests. Salamanders are both diverse and locally common in the lowland forest where they thrive in conditions that are, by anyone's standards, truly tropical. Temperatures are characteristically high and rainfall may be highly seasonal, limiting activity by salamanders to only a portion of the year.

Although ecologists argue over the causes and effects of tropical diversity, a given tropical habitat will generally have more predators, parasites, and competitors than a corresponding temperate habitat. By conducting field studies we have attempted to understand how tropical salamanders have not only managed to invade tropical communities but to flourish in them. One important aspect concerns community structure. In North America, coexistence of similar species is achieved by a number of mechanisms. For example, in salamander-rich areas of the Appalachians, the species in a local community are about equally divided between aquatic and terrestrial forms. In species with aquatic



James Hanken



Bob Ritter

*In ten milliseconds the salamander* Bolitoglossa adspersa, *above left, found in Colombia, can fire its tongue a third the length of its body, capture an insect, and return the prey to its mouth. The long tongue makes it largely unnecessary for bolitoglossine salamanders to pursue prey. *These two salamanders,* Hydromantes platycephalus *from Sonora Pass, California, right, and* H. italicus *from Liguria, Italy, below, belong to a genus with a remarkably disjunct distribution. The North American ancestors of* Hydromantes *dispersed into Asia, eventually reaching the Mediterranean. Mountain-building processes and climatic changes eliminated the habitat of the lungless salamanders so that only five species of* Hydromantes *are found today. Relict populations of two of the present species persist in caves and rock crevices in northern Italy, southern France, and Sardinia. The other three species survive in the mountains of central and northern California.*

reproduction, larval development may occur in springs, streams, or ponds, and breeding seasons may differ from species to species. Thus, both spatial and temporal overlap of larvae and, presumably, larval competition are reduced. Species that occur in the same habitat at the same time frequently differ in body size, and this is correlated with differences in the kinds and size of animal prey taken. All of these mechanisms may reduce competition between coexisting species.

Tropical salamander communities are different. As we have noted, all tropical salamanders are fully terrestrial, so separation along an aquatic-terrestrial gradient is not possible. Instead, two types of vertical segregation are especially important.

First, each tropical species has a narrow, precisely defined altitudinal distribution that frequently matches the complex, yet regular, elevational zonation of tropical plant communities. In this way, species present on the same mountain may actually never occur together because of nonoverlapping elevational distributions. Although altitudinal layering also occurs in temperate regions, it is never as pronounced as in tropical habitats.

At any given elevation and habitat, further sorting is achieved by different species living at different heights above or below the forest floor. Some burrow, others confine their activity to the ground surface, while many literally take to the trees where epiphytic plants, especially bromeliads, are favored retreats. Lacking a functional root system, bromeliads attach themselves to the trunks and limbs of trees and obtain necessary moisture and nutrients from the atmosphere. Like salamanders, bromeliads thrive in areas with excessive humidity, particularly the cool, fogbound cloud forest that cloaks the slopes of many tropical mountains. There, a diverse community of salamanders and other small animals has evolved in the aerial swamp created by the upward-directed, tightly overlapping leaves of bromeliads. The association between salamanders and bromeliads is hardly casual. Some salamander species occur nowhere else, and local densities can be great—as many as thirty-four salamanders have been found inside a single bromeliad in a Mexican cloud forest. We have found salamanders in bromeliads as high in trees as we have been able to search, and examination of recently felled trees (an all-too-common sight in the tropics) has revealed salamanders at least 100 feet above the ground.

Distinctive habits and habitat preferences of salamanders are often associated with morphological specialization, and several species, or even whole genera, are highly modified to survive in tropical environments. Arboreal montane species usually have small, flattened bodies that allow them to squeeze between tightly overlapping bromeliad leaves. Such species also possess a moderately prehensile tail and partially webbed hands and feet that adhere readily to wet leaf surfaces, providing great climbing ability. Burrowing forms have tiny limbs and extremely elongate bodies

and tails that almost make them vertebrate worms. Members of the genera *Thorius* and *Parvimolge* are true miniatures. Living among leaf litter and bark on the forest floor, some adults may be only one inch in total length. This brings them very near the minimum size limit for vertebrates, and they possess various skeletal and sensory modifications to accommodate their reduced size.

The most specialized of all tropical salamanders live in the wet lowland forest. During the day most species conceal themselves in bark crevices, leaf axils, or other relatively inaccessible sites. Emerging only at night, they cling to a tree trunk, plant stem, or leaf surface in wait of prey. (This behavior explains why even experienced field biologists have tended to overlook lowland tropical salamanders.) Ground-dwelling salamanders are scarce in the lowland tropics; almost all lowland species are either arboreal or subterranean. Arboreal lowland salamanders are even more highly specialized than their relatives in the montane cloud forest. A fully prehensile tail and extensive webbing, which in effect turns the hands and feet into suction cups, allow a salamander to suspend itself, even upside down, from stems and leaves.

During the evolution of tropical salamanders, a premium has been placed on adaptations that reduce activity and make the most of available energy. A prime example involves prey capture. Most nontropical lungless salamanders ingest insects, millipedes, and snails by partially flipping out a sticky tongue, then retrieving it with the prey item attached. Simultaneously, the salamander may lunge forward and seize its victim in its jaws, especially when the prey is large. Because the front of the tongue is anchored to the lower jaw, the back of the tongue is flipped out at the prey. This resembles the movement of a clenched fist resting palm up on a table top as the fingers are first quickly outstretched and then reclenched. The anterior attachment of the tongue means that prey can be attacked only at close range.

*Extensive webbing on the feet of this specialized species,* Bolitoglossa mexicana, *creates a suction cup effect, enabling the salamander to suspend itself from stems and leaves.*

Raymond A Mendez

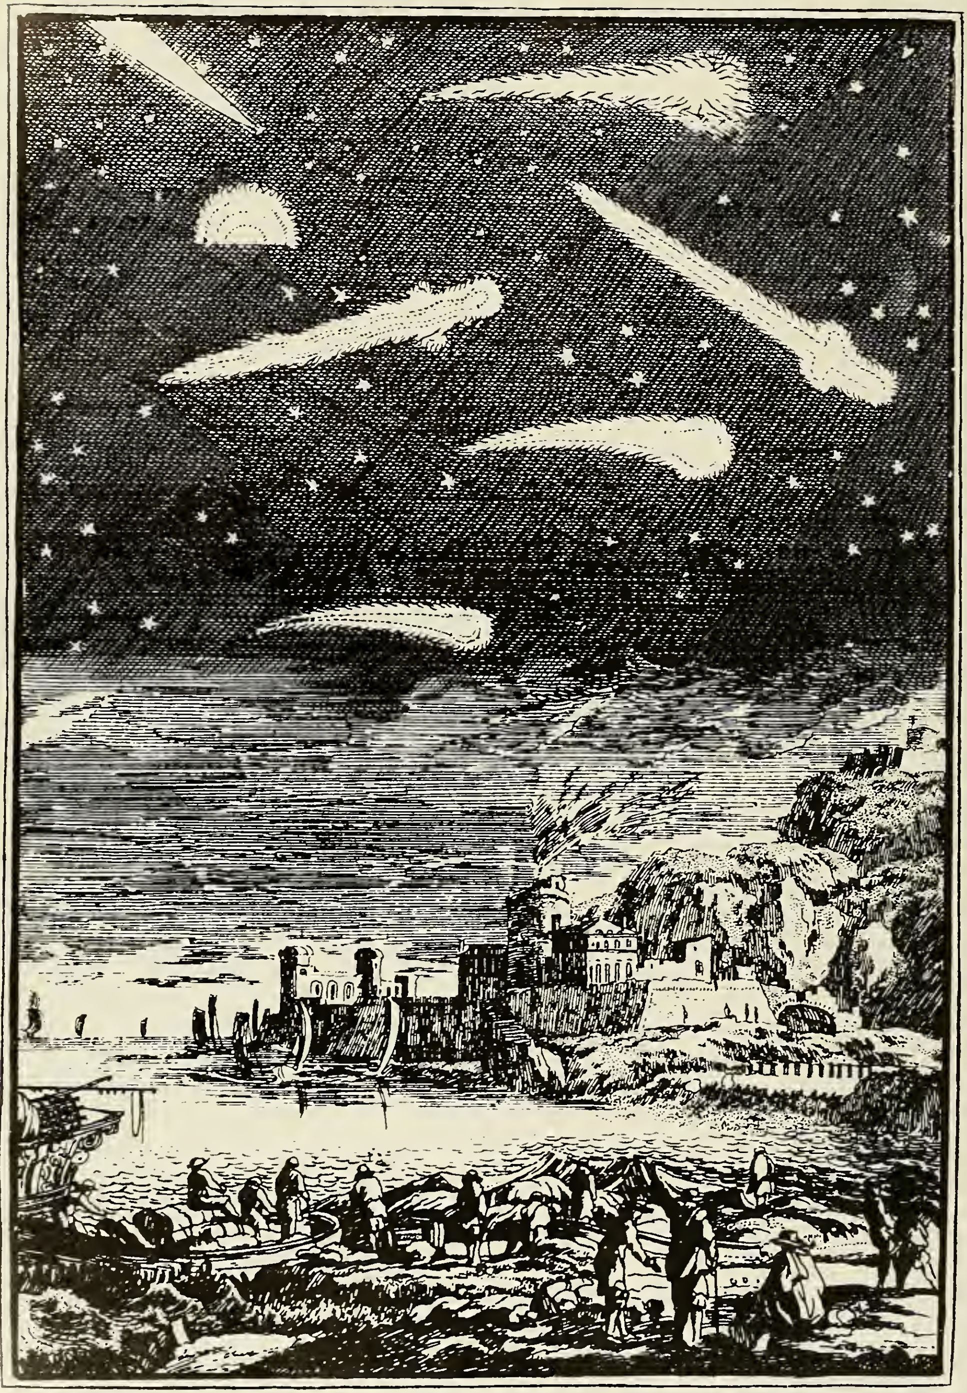
In contrast to this primitive pattern, the tropical salamanders have evolved a highly protrusible tongue that can be fired accurately for long distances at astonishingly high speeds. Careful laboratory measurements have shown that in the genus *Bolitoglossa* the tongue can be extended to about a third of a salamander's body length and returned to the mouth with a captured prey in as few as ten milliseconds. The evolution of this efficient prey-capturing system has required a complete reorganization of the musculature and skeleton of the tongue to allow the mushroom-shaped tongue, now no longer attached in front, to be catapulted from the mouth. As an additional refinement, bolitoglossines have developed the ability to control the direction of tongue projection. Thus, the salamander need not directly face or actively pursue its prey. A highly modified tongue structure means that a salamander can instead wait for prey to approach within its increased firing range.

Regional species diversity of tropical salamanders is greatest in areas that are geologically most active. To fully understand the regional patterns of adaptation and diversity in salamanders, we must consider geologic factors as well as behavior and morphology. Throughout much of Middle and South America large-scale tectonic processes, ranging from massive volcanic activity to lateral slippage of continental plates, have created new habitat, destroyed previously habitable areas, erected barriers to dispersal, and fragmented once continuous salamander distributions.

A particularly good example of the connection between geologic events and biotic diversity and distribution is seen in the genus *Chiropterotriton.* Eight species of this group are found in wet montane forests of Guatemala and adjacent Mexico and Honduras. Morphological, genetic, and ecological evidence agree that these species are more closely related to one another than to any other salamanders, insofar as they share a common ancestor. Each species is confined to its own mountain range or cluster of ranges, and no two species occur together. For tens of millions of years, this part of northern Central America has been the scene of violent geologic activity. The region straddles the juncture of three major crustal plates, and massive fault scarps crisscross a landscape dotted with some of the most spectacular volcanoes on earth. Originally continuous upland areas, some of which date from the early Cenozoic period, have been repeatedly fragmented by lateral faults, and large upland sections have been moved hundreds of miles from their original locations. Any ancestral *Chiropterotriton* species that inhabited the continuous upland habitat would have been fragmented into numerous subpopulations, each separated by impassible lowland barriers. Some of these isolated populations doubtless went extinct, but others continued to evolve independently, so that now each is sufficiently differentiated to qualify as a distinct species.

Why have salamanders experienced such a major adaptive radiation in the tropics? We can suggest the following explanations: (1) The prior evolution of a fully terrestrial life history preadapted bolitoglossine salamanders for life in the tropics, particularly in rugged, mountainous areas where free surface water is scarce, (2) limited activity, slow metabolism, and a simple, yet efficient, feeding mechanism allow salamanders to make slight energetic demands on an environment and invade and occupy otherwise closed tropical communities, (3) morphological specializations, including a diversity of locomotor patterns, (4) the availability of distinctly tropical microhabitats, especially arboreal bromeliads, enables more species to be packed into a given habitat, (5) restriction of species distributions to the narrow elevational zones of climate and vegetation characteristic of tropical environments increases local diversity, and (6) the extraordinarily high intensity of geologic activity in Middle America and northern South America has promoted the formation of new species, thereby increasing regional diversity.

Tropical salamanders provide an unusually favorable opportunity to study patterns of evolution. Our effort has spanned more than a decade, and has at various times included the collaboration of anatomists, physiologists, taxonomists, ecologists, biochemists, and geneticists. It is sad to note that thoughtless devastation of fragile tropical habitats by humans threatens to obliterate many of the most interesting pages of this story before they can be read. ☐



The Bettmann Archive

# The Comet Syndrome

*Human reactions to encounters of the cometary kind range from hysteria to frivolity*

**by Michael Oppenheimer and Leonie Haimson**

Comets have always been news, usually of the bad variety. Throughout history their spectacular arrival has provoked astonishment, consternation, and frequently, a sense of foreboding among observers. With Halley's comet due to reappear in 1985 and a space mission to a comet planned for the 1980s, it is worthwhile to recollect former attitudes toward comets.

Traditionally, people believed that comets presaged death in the form of wars, epidemics, or natural disasters. Aristotle pointed out that a comet appeared at the time of an earthquake and a subsequent tidal wave that swallowed the cities of Helice and Bura in the Peloponnesus, and in Biblical times it was commonly thought that the arrival of a comet accompanied the destruction of Sodom and Gomorrah.

Seneca wrote that "when one of these fiery bodies . . . appears . . . [men] know not whether to wonder or to tremble; for many spread fear on all sides, drawing from the phenomenon most grave prognostics."

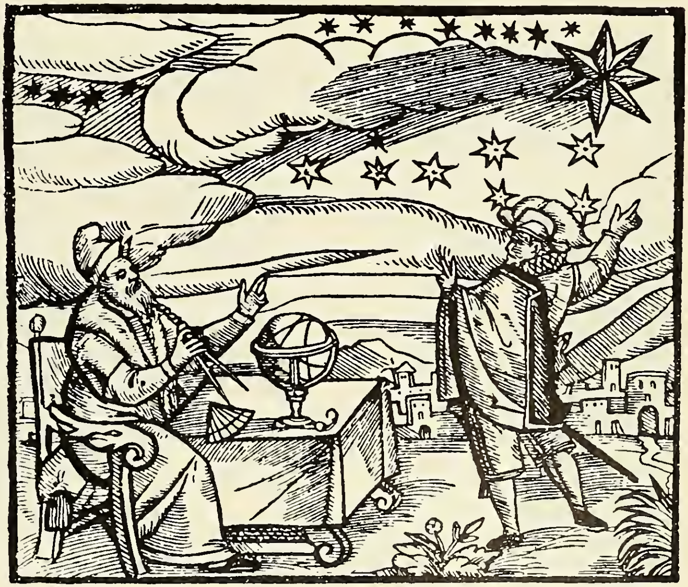
Most often, comets were interpreted as predicting the imminent demise of a prominent leader. Shakespeare echoed this belief in *Julius Caesar:* "When beggars die, there are no comets seen; The heavens themselves blaze forth the deaths of princes." Among the rulers whose deaths are known to have been marked by comets were Attila, the Roman emperor Valerian, and Julius Caesar himself.

Every plague and pestilence in the Middle Ages was supposedly connected with the materialization of a comet, and even if one did *not* show up when something untoward occurred (as with the death of Charlemagne), chroniclers noted their appearance nevertheless. When the year 1000 approached, the date itself convinced many that the end of the world was impending, and the sight of a genuine comet only exacerbated the general terror.

In the non-Western world, comets were also perceived as potential threats. In Japan, each time a comet appeared the reigning emperor summoned monks to his court to perform an exorcism rite and, for reasons that are obscure to us, he would prohibit the slaughtering of animals until the comet passed out of view. One emperor abdicated when confronted with the sight of a comet.

Several comets observed by the Aztecs in the late fifteenth century led them to believe that the end of the world and the return of their god Quetzalcoatl were imminent. To their profound regret, this encouraged them

*A French engraving, facing page, shows different kinds of comets that reminded the seventeenth-century artist of other objects. The fanciful version of a comet, below, adorned the title page of a late-sixteenth-century manuscript.*



The Granger Collection

to accept Cortés and his men with a mixture of resignation and awe when the invaders arrived in 1519.

One of most intense and widespread of comet scares arose in 1528. A French surgeon reported that a comet materializing in the skies that year "was so horrible and so frightful and produced such great terror in the vulgar that some died of fear and others fell sick." Various observers thought the comet looked like the "figure of a bent arm, holding in its hand a great sword, as if about to strike." This account is reminiscent of a reference in the Bible that some have taken to be a description of an ancient comet: "And David lifted up his eyes, and saw the angel of the Lord stand between the Earth and the Heaven, having a drawn sword in his hand stretched out over Jerusalem" (I Chron. 21:16).

By the seventeenth century, however, the belief that comets were necessarily evil omens was slowly beginning to be questioned by both scientists and the clergy. (Much later, Napoleon, whose own birth was marked by a comet, took the opposite view. While invading Russia, he announced that the comet of 1811 presaged his success against the enemy.) But even though most learned men were coming into agreement that comets were not harbingers of disaster, the general public continued to experience terror when they approached. As astronomy began to supplant astrology and the populace became convinced that a comet was simply a celestial object that moved past us, a new fear replaced the old one—that a comet would hit the earth. In 1758, John Wesley used the return of Halley's comet to preach the necessity of being right with God. "Were it to fix upon the earth . . . when it is some one thousand times hotter than a red-hot cannon ball, who does not see what must be the immediate consequence?" he asked.

In 1773, everyone in Paris began to talk about an upcoming lecture by the mathematician and astronomer Joseph-Jérôme Le Français de Lalande, entitled "Reflections on Those Comets Which Can Approach the Earth." The rumor spread that on May 20 a comet would destroy the earth, although Lalande publicly denied it. According to a contemporary French professor, "places in Paradise were sold at a very high rate," and people begged the Archbishop of Paris to pray to God to alter the comet's course.

The situation was repeated in 1828. Certain calculations published that year by the German astronomer Heinrich Wilhelm Matthaus Olbers (discoverer of two asteroids and five comets and originator of a method of determining the orbits of comets) purported to show that Biela's comet, due to return in four years, would come extremely close to the earth. A great alarm arose once again. People feared they would be destroyed by a violent

*One panel of the Bayeux Tapestry, a medieval embroidery that depicts the Norman Conquest, shows a comet moving toward King Harold II of England. In 1910, when Halley's comet was due to reappear, the Chinese issued posters of that panel to assure the public that the comet had passed by before with no ill effects.*

Epatant! *The comet of 1812 as it might have been viewed from the Pont Neuf in Paris.*

terrestrial shock or drowned in a universal deluge. The hysteria did not subside until *Tract on Comets* was published by Dominique François Arago, a French astronomer noted for his observations. It demonstrated conclusively that Biela's comet would come no nearer the earth than fifty million miles.

In the same book, Arago disputed various, commonly held misconceptions about comets. First of all, he argued against the prevailing theory that comets affected the weather, a belief that supposedly accounted for the superiority of wines made in the years during which comets passed by. One vintage year, for example, was noted for producing the "comet wine" of 1811. Comets were believed to cause higher temperatures and thus higher sugar content in the grapes from which wines were made. Arago showed, however, that the average temperature of comet years was no higher than normal. Even so, wine catalogs until the end of the nineteenth century continued to refer to the "comet wine" of 1811.

Arago also took issue in his treatise with the *Atmospheric Causes of Epidemic Diseases*, a popular work written in 1829, which claimed that "ever since the Christian era, the most unhealthy periods are precisely those in which some great comet has appeared." It further contended that such occurrences as earthquakes, fogs, and volcanic eruptions were linked with the effects of comets. Arago's protestations, however, provided only temporary comfort, and comets continued to be regarded with awe and terror down to the twentieth century.

Despite their generally baneful aura, comets have undeniably benefited one select group—their discoverers. Traditionally, comets are named for their discoverers; that small measure of immortality is often the greatest incentive for their search. Many astronomers throughout history have enhanced their reputations by being the first to sight a comet. Charles Messier, the eighteenth-century French astronomer known for his catalog of nebulae and star clusters, comes to mind. He discovered at least fifteen comets during his lifetime and thereby won recognition from King Louis XV who called him the "comet ferret."

Not all comets, however, are discovered by professional astronomers or dedicated comet hunters. Ordinary people have sometimes been first, often by accident. In 1861 an Australian sheep farmer discovered a comet. In 1910, a group of miners and railway workers spotted a new comet while walking home early one morning after their shift. More recently, in 1961, a comet was simultaneously discovered by a professional astronomer, a pilot, and an airline stewardess. And

not all astronomers have eagerly sought the fame that comet discovery tends to bring with it. Maria Mitchell, a young astronomer who lived on Nantucket Island, noticed a comet one night in 1847. At first she resisted her father's counsel to report the sighting to the director of the Harvard Observatory, but after much argument, she was persuaded to allow the sighting to be reported. She had, in fact, detected a new comet for which she eventually received the medal the King of Denmark awards annually to the discoverer of an important comet. Her reputation greatly enhanced, Mitchell subsequently became the first and until 1943 the only woman elected to the American Academy of Arts and Sciences in Boston. In 1865, she accepted a position at Vassar, where she had the use of the third largest telescope in the country, and she soon became celebrated for her brilliance as a teacher and a scientist. (For more on Maria Mitchell see "Women Astronomers" in the May 1979 *Natural History*.)

In recent years, the Japanese have dominated the discovery of comets. In 1959, Kaoru Ikeya, a young lathe operator who earned $28 a month, determined to redeem his family name from the disgrace of a father fallen into bankruptcy and alcoholism. For two years Ikeya ceaselessly worked on a telescope, grinding his own lens, and then for sixteen more months, he scanned the night sky. (This was a man whose personnel records listed him as lacking ambition and initiative.) Finally, on January 2, 1963, when he was nineteen, Ikeya's diligence was rewarded. He sighted a new comet, became a hero in Japan, and even played himself in a film based on his life. His hometown so appreciated his accomplishments that it converted an abandoned water tower, at public expense, to an observation dome for his personal use. Eventually, Ikeya discovered two more comets.

Ironically, Halley's comet—the most famous comet of all—which has been reappearing since antiquity, is not named for the individual who sighted it first (no one knows who that was). Halley's is the brightest comet that returns periodically into our view at relatively short intervals, approximately every seventy-five years. Throughout history it has been associated with a variety of pivotal events. Extrapolation indicates that in A.D. 66 it appeared while Jerusalem was under siege by the Romans, and one century later, it preceded by only a few months the Norman Conquest of England. In fact, in one of its panels the renowned Bayeux Tapestry, which chronicles the Norman Conquest, depicts a comet moving toward King Harold II of England. Then in 1456 when the Turks were attacking Belgrade, the comet again appeared, frightening both armies and causing Pope Calixtus III to call for special prayers so that the Christians might be spared disaster.

The periodicity of comets, however, was not established until the late seventeenth century. Newton observed the movements of a comet in 1680; two years later he studied another comet and attempted to describe its orbit mathematically. Edmond Halley, a young and gifted astronomer, visited Newton in 1684, and found that he had completed work on a theory of gravitation that, if valid, demonstrated that bodies mutually attracted would tend to move in elliptical, parabolic, or hyperbolic orbits. Halley convinced Newton to publish his results, and because the Royal Society of London lacked sufficient funds, Halley himself financed the printing of the work known as *Principia*.

For the next twenty years, Halley's energies were employed elsewhere, primarily in the study of navigation. Not until he was appointed to a chair at Oxford in 1704 did he return to the study of cometary movements. Applying the theories set out in *Principia*, he began to compute the orbit of the comet observed in 1682, and some twenty-four others. After long and careful work, Halley was surprised to discover that some of the orbits were elliptical; theoretically, therefore, comets with those orbits would return. More specifically, the orbit of the 1682 comet closely resembled the orbits of the comets of 1531 and 1607. When Halley referred to historical records, he found that various comets in earlier times could have been sightings of this same object as well and he estimated its period at seventy-six years. Finally, Halley extrapolated that this comet would reappear at Christmastime in 1758. Unfortunately, he died sixteen years before the comet was due to reappear. His reputation at his death was greatly enhanced by his work but not absolutely assured.

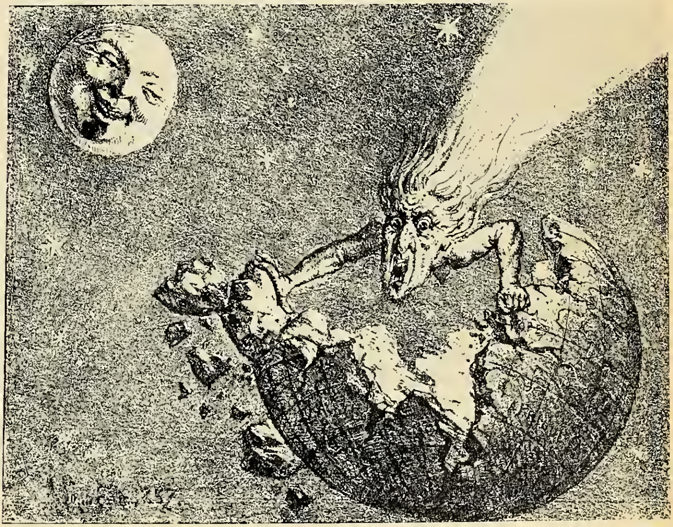
When the year 1758 rolled around, all the astronomers in Europe were eagerly, almost obsessively, scanning the skies. (According to Voltaire, no astronomer slept that year.) All the prominent comet hunters, including Messier, were involved in the search, yet the first to spot the comet—and to provide a significant confirmation of the general validity of Newton's theory of gravitation—was an amateur, a German farmer named Palitzch, who found the comet on Christmas night using a homemade seven-foot telescope. Halley was acclaimed when from that time on, by common consent, the comet was named for him.

When Halley's comet next returned in 1835, Mennonites in America, reportedly believing it foreshadowed the end of the world, allowed their crops to die on the vine. Many others were similarly fearful. A woman who lived in upstate New York and was twelve years old at the time remembered that "people were scared as wild geese. . . . We took out our sleds for a moonlight coast downhill. But we came right in. The snow was red as blood from the comet's glare—we didn't dare even to step on it."

Halley's comet approached the earth again in 1910, but this time the planet was due to pass through or very near the comet's tail. This had occurred with another comet in 1861, without any apparent ill effects, a fact with which the experts attempted to reassure the public. Yet as the year began, astronomers at Yerkes Observatory in Wisconsin made a possibly disturbing discovery. From spectral analyses, they determined that there was poisonous cyanogen gas in the comet's tail. According to a contemporary article in the *New York Times*, one of the scientists was "of the opinion that the cyanogen gas would impregnate the atmosphere and possibly snuff out all life on the planet." Most other astronomers disagreed, but a widespread feeling of foreboding remained, and when the comet was first sighted by eye in Curaçao on April 20, there were reports of alarm all over the world. From Rome to Mexico, people suffered great anxiety. In Chicago, a premature scare was set off on April 23, even before the comet came over the United States, when sudden darkness caused by weather conditions descended on the city for two hours. The phenomenon was gratuitously attributed to Halley's comet and some people became hysterical.

Nevertheless, as the comet came into view over the United States, feelings of excitement and exhilaration began to grow. The sales of telescopes increased sharply, and wholesale dealers reported that their supplies were exhausted. More telescopes were reputedly sold in the three months before the comet's arrival than in the entire period following the Civil War. According to the *Times*, the purchasers were drawn from all "classes," and they usually bought expensive instruments, "first-class telescopes that sell from $50 to $250. Many of the buyers set up their telescopes on the roofs of their apartments or houses, and on April 23 one of them received an un-

*A mid-nineteenth century French newspaper cartoon of what would happen if a comet collided with the earth.*



AMNH

anticipated bonus when, observing at night, he spotted a burglar trying to break into his brother's apartment.

Along with telescope sales, rumors also flourished as the comet approached. One was that when the tail passed through the earth's atmosphere, all the nitrogen would be converted to nitrous oxide, or laughing gas, and the world's inhabitants would cavort, transported, until they died. Another was that the comet might strike the earth's North Pole, displacing all electrical currents, and electrocuting everyone. Even some reputable scientists claimed that recent torrential rains in Europe were somehow related to cometary influence.

Astronomers, several of whom had certainly contributed unnecessarily to the widespread panic, were outraged that they were being blamed for withholding the full story. Thousands of accusatory letters about the comet flooded the Harvard Observatory. One professor complained that the letter writers "seem to think we are responsible for it."

Consternation spread all over the world. In Johannesburg, some enterprising men bricked up a room, installed cylinders of oxygen, and advertised in the local newspaper for "others who would share the expenses. . . . Numbers strictly limited." The wife of a prominent South African mine owner took up residence in a special chamber constructed at the bottom of one of her husband's mines. Chinese authorities issued posters of the Bayeux Tapestry to allay the general fear by showing that the comet had passed by before without harmful effects. In the American South, churches were packed and the fields were practically empty of hands. Many people sealed the doors and windows of their homes to keep from being poisoned and there were numerous stories of suicides and sudden breakdowns. "Comet pills" to counteract possible harmful effects were sold in the streets of Haiti, and according to one report, even in the United States. Mexicans gathered around crucifixes erected in the hills or sought refuge in caves and canyons.

Other, more sophisticated places had their own characteristic ways of celebrating the approach of the comet. The French seem not to have taken the whole affair as seriously as they had in previous eras. In Paris, special "comet suppers" were held at all the big cafes and restaurants. For days preceding the event, hawkers on the street offered postcards illustrating the presumed "end of the world," while "brooches and other pieces of jewelry representing the comet and its tail are sold in great numbers."

In New York, excitement built steadily. A new drink, "the comet cocktail," was invented at the Plaza Hotel and immediately became popular. The ingredients were kept secret, but its imbibers found that "it started with a fiery taste," followed "by a soothing sensation to the palate, and a general feeling of mental buoyancy." As in Paris, fashionable New Yorkers arranged private parties on the roofs of all the large hotels. At one particular gathering, a late-night dinner on top of the Gotham Hotel, the guests arrived in their motorcar togs and were supplied with small silver telescopes as favors.

Despite some urban festivities, certain ancient superstitions did persist. In Bermuda, for example, according to the *Times*, at the moment of the accession of King George V, "a sudden flaring up at the end of the comet's tail" was observed, leading many to expect a calamitous war would break out at some time during George's reign. (Five years later, when World War I was raging, a comet seen by the British on the Western Front was thought by them to herald tremendous casualties for their side, and seemed to them to be an "ally of the Central Powers.")

When the earth finally did pass through the comet's tail on May 18, 1910, a few auroralike flashes of light were observed, but that was all. There were no signs of cyanogen or laughing gas or electrical irregularities. At its height, however, the comet presented a spectacular appearance, displaying a tail that covered about one-tenth of the arc of the night sky. The *New York Times* concluded that on balance the experience was probably beneficial: "Superstition has received another blow, general interest in astronomy has been excited, and everybody has learned at least a little something about the heavenly bodies and their motions." But perhaps the most appropriate headline was the final one on May 26, "Pope NOT Impressed with Halley's Comet. Remarks On Viewing It That It Does Not Seem to Justify Commotion It Has Caused."

Comparatively few comets in history have been observable without a telescope. Of the approximately three hundred comets discovered in the nineteenth century, only thirteen were visible to the naked eye. Even fewer have been observable in daylight. Comet Ikeya Seki of the fall of 1965 (discovered by the same Ikeya already mentioned) was the only comet since the 1910 appearance of Halley's that was bright enough. Unfortunately, it was not widely seen in the northeast United States because of adverse weather conditions and because it appeared very early in morning.

The anticlimax provided by Comet Kohoutek is assuredly well remembered. Headlines appearing in various magazines in late 1973 and early 1974 chronicle the story. "Bright Comet May Light the Skies of Christmas" in April. "Bright Comet Next Winter" in May. "Comet of the Century" and "Get Set For the Sky Spectacular of the Century" in November. And, finally, "Flop of the Century?" and "Kohoutek the Tiny" in January. The cause of the dashed hopes was that Comet Kohoutek was relatively bright only while at a great distance from the earth, when it blew off volatile material as it approached the sun for the first time and heated up. After that mantle had dissipated, the comet's brightness returned to more average levels and the initial predictions of a spectacular sight proved premature.

Halley's comet, which will return in 1985, may also be a disappointment. Because of its position and that of the earth and sun, the comet will appear relatively faint to us when it should be at its brightest, after it passes the sun. But other comets will doubtless appear and may perhaps be seen trailing across the sky even by those not interested in astronomy or telescopes. If such a visitor from space should come by, be forewarned. Even now the sight of a comet may induce a sense of awe and perhaps bring a subtle twinge of fear to those who witness it. ☐

# Museum Menagerie

One tends to think of the American Museum of Natural History as a repository of bones, skins, fossils, and other relics of life. One would be startled to see a chimpanzee pedaling a kiddie car through the halls, for example, or a ferret riding an elevator.

The Museum, it turns out, has always been home to many eccentric living animals. As dusk gathers over the Museum, bats swoop down from the eaves and fly about looking for

*Alice Gray holding Blondie*

AMNH

# merican Museum

insects. In the Museum's rooftop greenhouse, cockroaches with numbers taped to their backs creep out of their hiding places. Hoping for a tasty mouse, a nine-inch toad from Surinam begins its nightly perambulations in the Department of Herpetology. Some Museum animals, such as the bats, are wild, while others are either participants in scientific research or the pets of staff members.

One of the most celebrated "pet" collections belongs to Museum entomologist Alice Gray. Gray and her menagerie, which includes scorpions, tarantulas, centipedes, cockroaches, and millipedes, have made television appearances on "To Tell the Truth," "What's My Line?" and the "Mike Douglas Show."

Scattered about in Gray's large and cluttered office are mayonnaise jars, glass cages, and plastic boxes crawling with exotic creatures. One of her favorites is the four-inch Madagascar hissing cockroach, the sight of which would make any apartment dweller grateful for his relatively tiny roaches. When disturbed, the Madagascar roach issues a loud, evil-sounding hiss by drawing air through spiracules in its chitinous shell. (Incidentally, it also uses these spiracules when molting; by sucking air through them, it bursts its skin down the back.) Cockroach enthusiasts are delighted to find numerous other species in Gray's collection, including Oriental, German, American, Australian, and green Cuban roaches, "giant" roaches and lobster roaches in cages along one wall.

The grande dame of Gray's tarantula collection is Blondie, who was raised from infancy in the Museum and is tame enough to be picked up and handled. Gray has other tarantulas, but most are too "frisky" to tolerate handling. Years ago, one of the tarantulas escaped from its cage. After several weeks, Gray received a

of Natural History

COSTUMES OF THE EAST, by Walter A. Fairservis, Jr., shows the great variety of exotic, romantic garments worn by the peoples of Asia, from the Middle East to China, from Lapland to Japan. Cultural and geographic aspects of the clothing are discussed, and beautiful color plates and black and white drawings show the rich detail of the costumes. Anthropologists, clothes designers, and devotees of Oriental art will appreciate the value of this book both as a reference and for sheer pleasure. Cloth $15.00, paper $5.95

ANCIENT MEXICO AND CENTRAL AMERICA, by Gordon F. Ekholm, analyzes the art and architecture of precolumbian Middle America. Superb color and black and white photographs by Lee Boltin picture items from the Museum's Hall of Mexico and Central America. Archeologists and sculptors will find this book beautiful as well as informative. Paper $5.00

BUTTERFLIES OF THE AMERICAN TROPICS, by William Phillips Comstock, is the definitive work on the genus *Anaea*. With 30 full-size color plates and hundreds of detailed drawings, this authoritative publication is a must for collectors of extraordinary books as well as for collectors of Lepidoptera. Cloth $25.00

CURASSOWS AND RELATED BIRDS, by Jean Delacour and Dean Amadon, explains and illustrates the habits and biology of curassows, guans, and chachalacas, a fascinating group of gamebirds from tropical America. This large volume has 30 magnificent color plates of paintings by Albert Earl Gilbert, George Miksch Sutton, and David Reid-Henry, as well as many drawings, photographs, and maps. Ornithologists and lovers of fine bird paintings will delight in this work based on several field trips and extensive research. Cloth $20.00

NATURALIST'S COLOR GUIDE, by Frank B. Smithe, is important to all naturalists, especially ornithologists, whether amateur or professional. Part I, a pocket-size binder with 86 swatches of named, measured colors, is essential for precise identification and description of birds and other animals. Part II, a paperbound supplement, discusses each color, how it was named and measured, and the work of various color specialists, such as Robert Ridgway. Part I $9.00, Part II $5.00, both parts together $12.00. Part III available soon.

Museum members may take a 10% discount. Send orders to:

*In the spring and fall of 1981 we repeat our popular program for travelers who enjoy outdoor things:*

Naturalist's Tour of the Scottish Highlands

MAY AND SEPTEMBER, 1981

We stay at small country inns and, by special permission, on the island of Rhum in the Inner Hebrides. We hike across moors, through forests and in unspoiled mountains among alpine flowers, sample local dishes and whiskey, meet Highland people and listen to the sound of bagpipes.

*Detailed brochures of this tour and a copy of our newsletter which lists all our fascinating travel programs, available from:*

The Rubáiyát of Omar Khayyám

This is a complete recording, delivered by Louis Zoul, of Edward Fitzgerald's 5th version, and is the cumulative effort of three men of genius.

It is followed by a few comments and comparisons, and also Pedro Calderon de la Barca's The Dream Called Life and Life is a Dream.

Lastly, beginning with Hamlet's soliloquy, there is some of Shakespear's best.

Among the kudos we've received, this came from a professor in Ethiopia: "It is beyond compare!" A Brooklyn lady wrote: "I play it over and over. It is my treasure." While from Canada a gentleman requested: "Because the record is such a beauty, send another one."

*A superlative delivery of superlative poetry*

$10.00

Now there is also available a companion book. It is hand bound and printed on high bulk long life archive book paper. Estimated duration - 500 yrs.

$15.00

New York 11104

call from someone who had found the spider wandering around Central Park some four blocks north of the Museum. "I recognized it," Gray explains, "by the balding pattern of hair on its abdomen."

Gray's collection was augmented last summer by two praying mantises: one found in a ladies' restroom on the forty-fifth floor of the Empire State Building; the other discovered on a window ledge on the thirty-eighth floor of a Wall Street office building. Apparently, Gray explains, the hapless insects were caught in updrafts of air from the hot city streets.

A different collection of fauna inhabits the Herpetology Department. All the animals there are part of research projects, except for the poisonous marine toad, which in the words of one assistant is "our public relations toad." Charles J. Cole, an associate curator, keeps a colony of female whiptail lizards. The study of these lizards, which reproduce entirely without males, is providing valuable information about parthenogenesis (reproduction by the development of an unfertilized egg), adaptation, and ecology.

Next door, curator Charles W. Myers's office is crowded with South American poison-dart frogs. He is

### Ownership Statement

Statement of ownership, management, and circulation (required by 39 U.S.C. 3685) of *Natural History*, published twelve times a year at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024, for October 1, 1980. General business offices of the publisher are located at Central Park West at 79th Street, New York, N.Y. 10024. Publisher, David D. Ryus; editor, Alan P. Ternes, Central Park West at 79th Street, New York, N.Y. 10024. Owner is the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024. Known bondholders, mortgagees, and other security holders owning or holding one percent or more of total amount of bonds, mortgages, or other securities: None. The purpose, function, and non-profit status of this organization and the exempt status for federal income tax purposes have not changed during preceding 12 months (Section 132.122, Postal Service Manual). The average number of copies of each issue during the preceding 12 months are: A. Total number of copies printed: 508,337; B. Paid circulation: 1. Sales through dealers and carriers, street vendors, and counter sales: 11,710; 2. Mail subscriptions: 457,726; C. Total paid circulation 469,436. D. Free distribution by mail, carrier, or other means: 17,094. E. Total distribution: 486,530. F. 1. Office use, leftover, unaccounted, spoiled after printing: 8,708. 2. Returns from news agents: 13,099. G. Total: 508,337. The actual number of copies of single issue published nearest to filing date are: A. Total number of copies printed: 495,114. B. Paid circulation: 1. Sales through dealers and carriers, street vendors, and counter sales: 11,309. 2. Mail subscriptions: 461,844. C. Total paid circulation: 473,153. D. Free distribution by mail, carrier, or other means: 5,017. E. Total distribution: 478,170. F. 1. Office use, leftover, unaccounted, spoiled after printing: 4,693. 2. Returns from news agents: 12,251. G. Total 495,114. I certify that the statements made by me above are correct and complete.

# NATURAL HISTORY

A Buddha in the Sukhothaian style, in bronze. It is in a display of Buddhas at the Gardner D. Stout Hall of Asian Peoples, American Museum of Natural History. Photography, with support from the Henry Luce Foundation, by Lee Boltin.

working on a collaborative study of the highly toxic, biomedically important alkaloids secreted by these brilliantly colored frogs.

For a number of years, the Mammalogy Department was the home of a family of ferrets. Two of these small, weasellike animals, a male and an albino female, were given to the tannery to be reduced to study skins and skeletons. Instead of turning them into skins and bones, the tannery technician adopted them as pets. Peppy and Peppina had several litters before they died, and the last of their offspring, Jeb, was a Museum favorite. He had the run of the place and even learned to ride the elevators. One day, however, he met with misfortune and fell down the elevator shaft. Telling of the accident, a technician in the department sadly shakes his head. "No more ferrets," he says.

Of all the animals that have inhabited the Museum, none was more beloved than Meshi, a chimpanzee. Henry C. Raven, a staff anatomist, found Meshi in the French Cameroons in 1929 and brought the orphaned animal back to New York. Raised in the Raven home as another child (one of the first times such an experiment had been tried), Meshi was a frequent visitor to the Museum. Her favorite pastime was riding a kiddie car back and forth along the Museum's fifth-floor corridors. She often lunched with the president of the Museum, Henry Fairfield Osborn. On these occasions, Meshi would ride her kiddie car to the elevator, descend to the second floor, and pedal into the staff dining room, where she would eat with a spoon while seated in a high chair.

When, like most pet chimpanzees, she became morose and violent in the later years of her life, Meshi was given to a zoo in Chicago. When she died, her body was shipped back to New York where Museum preparators mounted it. Today, visitors to the Museum can see her in the Hall of Primates, sitting on a log, with a contemplative, philosophical look in her glass eyes.

*Douglas J. Preston*

**Expedition to New Guinea**

In 1953, acclaimed Museum ornithologist Thomas Gilliard embarked on an expedition up New Guinea's Sepik River to visit regions previously unexplored by scientists. For the December Members' Program, Mary LeCroy, another Museum ornithologist, will show Gilliard's film of the expedition and talk about his work in New Guinea. LeCroy, who is an expert on New Guinea birds of paradise, will present the *Sepik River Expedition* on Wednesday, December 17, at 7:30 P.M. in the Auditorium. Members are admitted free; $3.50 for nonmembers.

**African Music and Dance**

*Dinizulu and His African Dancers, Drummers, and Singers* will present two narrated concerts in the Auditorium on Sunday, December 14, at 1:00 and 3:00 P.M. The program will include such dances as the *Egungun*, a secret-society dance of Nigeria, and the *Bamaya*, a Ghanaian dance of gaiety and dignity. Other highlights of the afternoon will be singing and solo performances on the thumb piano and drums. The concerts are free.

**Man and Nature**

Four films on the subject "Man and Nature" will be shown in the Auditorium on December 6 and 7, from 2:00 to 3:15 P.M. The films, which are free, include *Beluga Baby*, about a whale born in captivity; *Osprey*, about the return of this bird to the Scottish Highlands; and *Mysterious Castles of Clay*, about the African termite and its monumental nests.

**Theater of the Deaf**

Four deaf actors and one hearing actor will present a theater piece based on the life of the Japanese poet Issa. This free program, given at 2:30 P.M. in the Auditorium on December 27, 28, 29, and 30, is especially suited for children. *The National Theater of the Deaf* is presented in association with the Touchstone Center.

**Holy Land Before Christ**

Claireve Grandjouan, professor of classics at Hunter College, will give a slide lecture, *The Holy Land Before Christ*, in the Auditorium on Wednesday, December 3, at 7:00 P.M. She will discuss the most recent archeological finds in the Near East and how they shed light on the region's ancient civilizations. Tickets are $5. Call (212) 873-7507 for ticket availability.

**Courses for Stargazers**

The American Museum–Hayden Planetarium is offering a winter semester of courses in astronomy, aviation, navigation, and astronomy for young people. Course catalogs and preregistration forms may be obtained by writing to the Planetarium.

# Additional Reading

**South Bronx Miracle** (p. 26)

B. Myerhoff's *Number Our Days* (New York: E.P. Dutton, 1979) is an anthropologist's personal account of her studies of elderly Jews in a senior citizens' center in California. An excerpt from the book appeared in the March 1979 issue of *Natural History*, pp. 76–85. Myerhoff collaborated with A. Simic on an anthology entitled *Life's Career—Aging* (Beverly Hills: Sage Publications, 1978), an exploration of aging in several ethnic groups. A classic in the field of gerontology, *Middle Age and Aging*, edited by B.L. Neugarten (Chicago: University of Chicago Press, 1968), is a collection of articles written in a sociopsychological framework, including A.M. Rose's "The Subculture of Aging" and G.F. Stribe's "Are the Aged a Minority Group?" M. Clark's "The Anthropology of Aging: A New Area for Studies of Culture and Personality" (*The Gerontologist*, vol. 7, 1967, pp. 55–64) proposes that the study of the elderly as a subculture is a valid anthropological inquiry. In *Culture and Aging* (Springfield: Charles C. Thomas, Inc., 1967), M. Clark and B. Anderson consider which personality types deal successfully with growing old.

**Weeds** (p. 36)

W.C. Muenscher's illustrated text *Weeds* (New York: Macmillan, 1960) identifies these plants and provides information about their control. *Weeds of Lawn and Garden*, by J.M. Fogg, Jr. (Philadelphia: University of Pennsylvania Press, 1943), illustrated by L. Hagerty, is a standard handbook of weeds for eastern temperate America; L.J. Crockett's *Wildly Successful Plants* (New York: Macmillan, 1977), illustrated by J. Bradley, is a handbook of North American weeds with an extensive bibliography. Written and illustrated by A.O. Dowden, *Wild Green Things in the City* (New York: T.Y. Crowell Publishers, 1972) introduces the characteristics of common urban plants during various months of the year. A textbook of plant synecology, R. Daubenmire's *Plant Communities* (New York: Harper and Row, 1968) provides an excellent general treatment of succession. F.H. Bormann and G.E. Likens's *Pattern and Process in a Forested Ecosystem* (New York: Springer-Verlag, 1979) describes a research team's work on regeneration after disturbance in the Hubbard-Brook Forest in New Hampshire. *Plant Strategies and Vegetation Processes*, by J.P. Grime (New York: John Wiley and Sons, 1979), discusses the evolutionary characteristics and life history strategies of plants. In "The Population Biology of Dandelions" (*American Scientist*, November–December 1971, pp. 684–94), O.T. Solbrig explains how these common, successful weeds are adapted as a group to taking advantage of environmental disturbance. R.H. Whittaker's *Communities and Ecosystems* (New York: Macmillan, 1975) is a general, illustrated text that includes a large bibliography. For a review of the literature on weeds, see H.G. Baker's "The Evolution of Weeds" in *Annual Review of Ecology and Systematics* (vol. 5, 1974, pp. 1–24).

**Tropical Salamanders** (p. 46)

Much of the literature on tropical salamanders is technical. The Grzimek *Animal Life Encyclopedia* (volume 5), however, has a large, readable section on tropical salamanders. For a comprehensive, illustrated review of the subject, readers should consult D. Wake and J. Lynch's "The Distribution, Ecology, and Evolutionary History of Plethodontid Salamanders in Tropical America" (*Science Bulletin, Natural History Museum of Los Angeles County*, 25: 1–65, November 19, 1976). "Genetic Differentiation, Albumin Evolution, and Their Biogeographic Implications in Plethodontid Salamanders of California and Southern Europe" (*Evolution*, vol. 32, 1978, pp. 529–39), by D.B. Wake, L.R. Maxson, and G.Z. Wurst, presents data concerning genetic differentiation among the five species of *Hydromantes*. A two-article series by R.E. Lombard and D.B. Wake entitled "Tongue Evolution in the Lungless Salamander, Family Plethodontidae" explores in detail how the salamander tongue works. The first article, "Introduction, Theory, and a General Model of Dynamics" (*Journal of Morphology*, vol. 148, 1976, pp. 265–86), includes many diagrams and a photograph showing a retracted *Hydromantes* tongue; the second, "Function and Evolutionary Diversity" appeared in volume 153, 1977, pp. 39–80. Both articles include helpful bibliographies.

**Comets** (p. 54)

Illustrated with many photographs, P.L. Brown's *Comets, Meteorites and Men* (New York: Taplinger Publishing Co., 1974) is a thorough introduction to the physical nature of comets that explains many aspects of comets and meteorites, including their different components, what their motions reveal about different theories of the solar system, and the scientific controversies that exist about them. Another illustrated introduction to comets, P.

Moore's *Comets* (New York: Charles Scribner's Sons, 1976), discusses the basic structure of a comet and its relation to the solar system and gives accounts of some successful comet hunters and their finds. Among the comets discussed in this book are Biela's and Halley's comets and the disappointing Comet Kohoutek. R.S. Richardson's *Getting Acquainted with Comets* (New York: McGraw-Hill, 1967) is an illustrated, easy to understand text with instructions on comet watching for beginners. For a discussion of the origin and formation of comets and their tails, see R.A. Lyttleton's *The Comets and Their Origin* (Cambridge: Cambridge University Press, 1953). "When Halley's Comet Bemused the World," by J. Klein (*The New York Times Sunday Magazine*, May 8, 1960), is about the comet's 1910 appearance and T. Morris's "The Boy Who Redeemed His Father's Name" (*Reader's Digest*, January 1966) tells the story of comet finder Ikeya. "A Sad Tale of Two Comets" (*Astronomy*, February 1980) describes the NASA mission that will explore Halley's comet and Tempel 2. A good source of scientific literature on the subject is the large, two-volume work published by NASA entitled *The Study of Comets* (Washington, D.C.: Scientific and Technical Information Office, NASA, 1976), edited by B. Donn, M. Mumma, W. Jackson, et al. This collection of papers is from IAU Colloquium No. 25, held at the Goddard Space Flight Center, Greenbelt, Maryland. Among the papers that appear in this comprehensive work is M. Oppenheimer's "Gas Phase Chemistry in Comets" (vol. 1, pp. 753–63).

# Celestial Events

### by Thomas D. Nicholson

**The Moon** Evening skies are dark and moonless for the first week in December (and again in January) because the waning crescent will be in the morning sky. New moon occurs on December 7. The first evening view of the young crescent moon should be possible on about the 10th. First-quarter is on the 14th, full moon on the 21st, and last-quarter on the 29th. The new moon will appear again on January 6th and first-quarter will be on the 13th. Apogee moon (farthest from the earth) is on December 2 and 30 and perigee moon (nearest the earth) is on December 18 and January 14.

**Stars and Planets** Every planet but Mars is a morning star for most of December and all but Mars and Mercury continue in the morning sky through January. Planets, as you might expect, are thus poorly represented in the evening sky. The morning planets fortunately more than make up for the deficiency. Jupiter and Saturn rise near one another about midnight; Venus about an hour before dawn. Best dates are December 1 to 4 and 28 to 31 when the waning moon is passing the planets. The sun moves out of the constellation Ophiucus and into Sagittarius after mid-December. Mercury leaves Libra, passes through Scorpius and Ophiucus, and joins the sun in Sagittarius in late December, moving ahead of it into Capricornus in January. Venus follows the same path through Libra, Scorpius, and Ophiucus, but stays behind the sun, leaving Ophiucus and entering Sagittarius in early January. Mars is in Sagittarius for most of December, Jupiter and Saturn are in Virgo, Uranus is in Libra, Neptune is in Ophiucus, and Pluto is in Bootes.

December 1: From moonrise (about midnight this morning) until dawn, the moon is very close to Jupiter and Saturn (Jupiter is the brighter of the two). Venus, brighter still, rises below them and to their left before dawn.

December 4–5: The waning moon is near Venus on these two mornings. Jupiter and Saturn are well above them to their right.

December 8: Earliest sunset of the year (north of the Equator).

December 9: The setting moon may help you find Mars tonight, in the west below the moon about an hour past sunset.

December 13–14: Look for the Geminid meteors on either morning, a reliable and productive (50 per hour) shower.

December 21: The sun arrives at the winter solstice and winter begins in the Northern Hemisphere at 11:56 A.M., EST. This is the shortest day of the year north of the Equator.

December 22: The Ursid meteor shower is at maximum (about 15 per hour).

December 28–29: Jupiter and Saturn are much closer to each other than earlier in the month. The moon passes them again tonight.

December 31: Mercury aligns with the sun in superior conjunction (beyond the sun), entering the evening sky.

January 1: Earth is nearest the sun (perihelion), about 147,093,000 kilometers (91,400,000 miles) from it.

January 6: The latest sunrise of the year occurs north of the Equator.

January 14: Jupiter and Saturn are in conjunction.

**Evening Star Map:** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you face the other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the sky at about 11 to 12 P.M. on December 1; 10 to 11 P.M. on December 15; 9 to 10 P.M. on December 31; and 8 to 9 P.M. on January 15. It shows only planets and moon phases above the horizon at those times.

Helmut Wimmer

"Gives you everything that counts.... a guide all tree lovers will want."
—*Michael McCloskey, Executive Director, Sierra Club*

**THE COMPLETE TREES OF NORTH AMERICA**
is the quickest, easiest, surest guide of its kind.

**Examine this superb field guide and natural history free for 15 days!**

☐ identifies nearly 800 species
☐ over 2,000 labeled illustrations
☐ illustrated summer and winter keys
☐ over 650 range maps

This encyclopedic reference by **Dr. Thomas S. Elias** provides easy access and fascinating information. Species text and illustrations are coordinated. Trees can be found by common or scientific names. You can find, at a glance, relationships of families, genera, species. A natural history as well, this modern classic offers a wealth of information on ranges, habitat, growth stages, forestry, and much more. *An Outdoor Life/Nature Book* from Van Nostrand Reinhold. 960 pages.

**Includes drawings from 1905 and 1922 editions of Sargent's *Manual of the Trees of North America*—and new illustrations by noted botanical artist Ruth Brunstetter. Dr. Elias is assistant director of the Carey Arboretum of the New York Botanical Garden.**

VNR **VAN NOSTRAND REINHOLD**

# A Gathering of Birds

### by Robert Arbib

A Field Guide to the Birds, by Roger Tory Peterson (fourth edition). *Houghton Mifflin Company, softcover $9.95; hard-cover $15.00; limited signed edition $90.00; 384 pp., illus.*

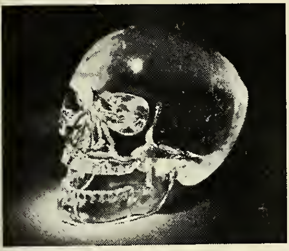
The news has already reached the farthest corners of the continent, and armies of birders, kitchen window watchers, and librarians are already rushing to snap up the long-awaited, "completely revised and enlarged" edition of Peterson's original launching pad to fame and fortune, his eastern guide. It is thus uncertain in the mind of this reviewer whether to treat its arrival as a historic event or to review it as an addition to the ever-more-crowded shelf of field guides.

As an event, it signals the first revolutionary revision of the field guide that started it all in 1934, and which, after one minor and one major revision, has sold almost two million copies. But more than that—as has so often been said (every time the author wins another prestigious medal or honorary degree)—it is the book that did more to popularize natural history and father the conservation movement than any other, including even Rachel Carson's *Silent Spring.*

As advertised, this edition is almost completely new and represents a quantum leap forward from its most recent predecessor, and here some specifics are in order. Several immediate improvements should be noted at once: the color plates, at last, now face the text for the species shown—no more searching for text and corresponding illustration on widely separated pages. For the first time there are excellent range maps—390 of them—the work of Virginia Marie Peterson (principally) and her husband, Roger. Not postage-stamp maps either, but six to a page, legible maps with state and province boundaries shown. The color scheme is borrowed, perhaps, from the Robbins-Bruun-Zim-Singer field guide: pink for breeding range, blue for winter range, purple for overlap, with many marginal notes, such as (for rose-breasted grosbeak) "winters casually to n. U.S. at feeders," or (whip-poor-will) "recent decline in many areas."

Another cried-for improvement is the updating of the bird list itself, with literally scores of species added to the text and shown in color plates. I counted an additional 137 species or forms in this present edition; most

Our history is your heritage.
Preserve it for our future generations. . .



This photo is of the Maya Crystal Skull and is an example of the subjects that you can read about. Popular Archaeology is a magazine on world-wide archaeology that is written in an easy-to-read style and is well illustrated. You will receive articles on the pyramids of Egypt, American archaeology, Roman and Greek archaeology, human evolution, the scientific methods used in archaeology and notices on opportunities to do field work. We are now featuring a continuing column entitled "The Unexplained." Edited by professional archaeologists, you can read into "The Mystery and Excitement of the Search and Excavation" and discover factual material about the history of our civilization. Subscription is $9.75 for one year, $15.00 for two years and $20.00 for three years, all of which are guaranteed. Each new subscription will include free good-reading back issues.

**POPULAR ARCHAEOLOGY**

P.O. BOX 4211 ARLINGTON, VIRGINIA 22204

*Let Them Grow With a Questar*

Children with intense curiosity about the nature of things will learn to master many tools, and the telescope, that prime tool of science, should be the first. Only the finest telescope, combining mechanical and optical perfection, can become a true extension of the mind and hand. Such an instrument is the Questar, and its lovely versatility adds an extra dimension to many fields: astronomy, terrestrial studies, or perhaps simply to the pure enjoyment of wildlife. What else could you buy a child that would enchant, amuse and continue to serve for a lifetime?

*Send for our booklet in color on the portable, photovisual Questar. $2, please, to cover mailing on this continent. Airmail to S.A., $3.50; Europe and N. Africa, $4; elsewhere, $4.50.*

QUESTAR

Box GY, New Hope, Pa. 18938 (215) 862-5277

are the result of knowledge gained by amateurs in the explosive growth of birding in eastern North America. The list of ocean wanderers—vagrants from the West, from Europe, and from the tropics—is truly remarkable and there are new color plates for each. Included are the many escapees—parrots and waterfowl especially—that have been found, some thriving, in the wild. Newcomers to birding who couldn't understand why common birds like the cattle egret or house finch were nowhere in the third edition will find them here.

Of all the features of the book, the color plates will undoubtedly draw the most comment. This edition has 136 full pages in color, as against the previous edition's 42. To get an idea of the simply prodigious labor that went into them, my tabulation showed 803 individual birds full figure, standing or sitting; 528 flying; 210 heads or heads and necks; 37 miniature birds; 34 drawings; 25 silhouettes; 7 chicks, 6 tails; 2 wings; and 14 separate feet. A grand total of 1,666 separate and distinct portraits, absolutely unguaranteed, but I'm not going through that again! Virtually every pose is here: mostly side views, but also those of birds flying, from above and below. The only views that are missing are the ones I have most need of in a field guide—the north end going south. The paintings themselves seem vastly superior to those in earlier editions.

As for the accompanying text, page layouts have imposed maximum brevity. Especially brief are the paragraphs on range, but the maps replace the words splendidly. We must not forget that this is a *pocket* field guide; it cannot illustrate every possible plumage of every species. Its system depends on key field marks as cues in an elimination process, and in most cases it will narrow the choices to one. In a few instances the guide suggests alternates for later, at-home decisions, but inevitably you will encounter puzzles that neither this nor any field guide can solve. You may be surprised to find that this edition, with so much added, is no larger than its predecessor. This is a feat I don't understand.

Negatives? The soft-cover edition and the dust jacket of the hard-cover are a hateful billboard, with a line across the bottom that screams "COMPLETELY NEW!" Fifteen years from now, when my copy is

Cruising expeditions to the
**Seychelles**

Two unusual itineraries.

Singapore to Seychelles — Sumatra, Burma, Andaman Is., Sri Lanka Maldive Is. Study the unique plants, animals, and marine life of the "Garden of Eden" islands. Informative lectures / guidance by expert naturalists.

Seychelles / Red Sea — Djibouti, Sudan, Egypt, Petra, Suez Canal, Cairo. Fine accommodation / cuisine on our MS WORLD DISCOVERER — the world's most sophisticated expedition cruise ship. From $4100. Departs April. Write for details.

*Better Than Jogging*

NordicTrack

**Revolutionary new CV exerciser duplicates XC skiing for the best motion in fitness.**

**More muscles exercised**
Arms, legs and shoulders uniformly share the workload. Keeps more muscles in tone. Makes high heart rates very easy to attain. Involves more of the body's CV system.

**Completely jarless, stand-up exercise**
No joint or back problems as in running or jogging. Provides more uniform leg muscle loading than exercise bikes.

**A highly effective proven product**
Used in homes, companies and institutions such as Xerox Corp., YMCA, Penn State U., and the U.S. Army. NordicTrack employs no motors. Arm and leg resistances are adjustable. Portable, folds for convenience.

nature
tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers... rain forests, mountains, and tundra... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

dogeared and ragged, it will still shout "COMPLETELY NEW!" at me, even though it will lack the twenty-five new additions to the regional bird list that will probably have been added since 1980.

Of course, most of the attention will be focused inside the covers. Already we have heard from a few of the hypercritical "experts," ready with magnifying glass to pounce on any suspected error. Isn't this bill too thin, those legs too long, the breast here too bright, the wings there too short? I'll leave this nitpicking to others. I did find some colors that particularly bothered me. In the copies I have seen, some plates have trouble with their blues: the American coot has a strong blue cast, those enormous (why so big?) kingfishers are solid blue, but the blue grosbeak is decidedly purple, and the robin-bluebird plate seems washed out. The answer may be in the printing of sixteen pages of color plates on each sheet: balancing colors accurately so that all are correct is difficult and may be impossible. Suffice it to say there are no illustrations that might cause confusion between species—save perhaps the *Empidonax* flycatchers, which are better separated by voice and habitat anyway. The new Peterson guide was not designed to solve those really difficult identification problems: all the immature gulls, cryptic flycatchers, problem raptors, juvenile pelagics, and uncommon hybrids. We need special, detailed field guides for those.

There may be people who will closely examine the maps and find fault with minor details. And for some species all the state and provincial boundaries should probably not have been included. They pin the map maker down to specifics where knowledge is still vague. But these are fine maps and having them all together in one section will make future revisions simpler.

So, finally, the time has come to retire your third edition to the shelf for good. This new Peterson was worth waiting for, and it's all you'll need in your kit bag for some years to come. Don't walk—run to your nearest bookseller!

*Robert Arbib writes for the National Audubon Society and also edits their bimonthly magazine,* American Birds. *His book,* The Lord's Woods, *won the John Burroughs medal as the outstanding nature book of 1972.*

## Resorts

BELIZE—RUM POINT INN, Placencia. Personalized vacation maximum 8; snorkle largest reef in hemisphere; visit unfrequented Mayan Ruins; experience other cultures while enjoying private seaside cabins, interesting cuisine. Write 3526 Old Onslow Road, Greensboro, NC 27407

FAR OFF THE BEATEN TRACK: Very small, very special hotel tucked into a 30-acre plantation on the island of Bequia, St. Vincent Grenadines, W.I. 12 rooms, pool, tennis, snorkeling, beautiful beach. Write or call: Spring On Bequia, Box 19251, Minneapolis, MN 55419 (612) 823-1202

FREE! Map/Birdlist—Chiricahua Mountains Area—plus illustrated brochure of our nature lovers' retreat—Cave Creek Ranch, Box F-1, Portal, AZ 85632

MAINE: Remote fly-in XC ski lodge. Outstanding backcountry touring, beginner to expert. Warm comfortable cabins, excellent food, sauna, maximum 10 guests. Little Lyford, Brownville, ME 04414

## Tours/Trips

ADVENTURES with WHALES and WILDLIFE. Observe whales in Baja lagoons and off Maui, Hawaii. Wildlife adventurese in Tanzania, Kenya, Zambia and Zaire. Also Andes, Amazon, Galapagos, Nepal, India, Australia, New Zealand and Alaska. 1981 trip preview available. Adventures International, 4421-N Albert, Oakland, CA 94619

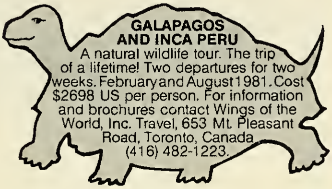
ADVENTUROUS SUBCONTINENT, Select Seasonal Tours: Grand India-Nepal Highlight, January Republic Parade. Geeta Tours, 1245 Jarvis, Chicago, IL 60626

ANALYZE CARNIVAL TRADITIONS in Brazil, explore marine environments in the South Pacific, excavate a medieval town in West Africa, observe whale behavior in Baja, map ancient Egyptian tombs, collect unusual plants in Peru. You can help University scholars on field expeditions winter, spring, or summer. No previous experience necessary. Contact University Research Expeditions Program (NH), University of California, Berkeley, CA 94720 (415) 642-6586

ARCTIC CANADA. Musk oxen, caribou, nesting peregrines and gyrfalcons! Archaeology. June 27–July 6, 1981. Contact Cloud Ridge Naturalists, Ward, CO 80481

GALAPAGOS: For the best Galapagos experience, hike and sail the Islands with our small groups. Peru—Machu Picchu options and horseback expeditions. Inca Floats, 5982 N. Balboa, Oakland, CA 94611 (415) 339-9095

HIMALAYAN TRAVEL, INC. Trekking expeditions in the Everest and Annapurna areas of Nepal. Free brochure. Box 481-NH, Greenwich, CT 06830. Toll free (800) 243-5330



**GALAPAGOS AND INCA PERU**

A natural wildlife tour. The trip of a lifetime! Two departures for two weeks. February and August 1981. Cost $2698 US per person. For information and brochures contact Wings of the World, Inc. Travel, 653 Mt. Pleasant Road, Toronto, Canada (416) 482-1223.

MEXICAN & CENTRAL EXPEDITIONS by Wayne Hussing, 11120 Raphel Road, Upper Falls, MD 21156 (301) 592-7247—White water Rafting—Volcanic Climbs—Backpacking—Jungle Exploration—Overland Drives, Oct–July

NATURALIST GUIDED FIELD SEMINARS and tours, West Texas and Mexico. Rafting, hiking, backpacking, bus. University or Continuing Education credit as appropriate. Write Education Department, Chihuahuan Desert Research Institute, Box 1334, Alpine, TX 79830

NATURALIST'S DELIGHT! Baja California, Mexico. Whale-watching! Photography! Birding! Wilderness! Incredibly individualized escorted environmental explorations—$1485. Baja's Frontier Tours, 4365-H New Jersey, San Diego, CA 92116 (714) 299-1360

NATURE TOURS emphasizing birds, wildflowers, mammals. Small groups to Central, South America, Galapagos, China, Western America, Britain, Kenya, New Guinea, Australia, and more. Write for brochure. World Nature Tours, Box 693a, Silver Spring, MD 20901

NEW ZEALAND WALKABOUT: Escorted nature tours featuring excursions in New Zealand's scenic National Parks, plus the Milford Track. Pacific Exploration Company, Box 3042-N, Santa Barbara, California 93105

PERU: FOLKLORE/MUSIC/ARCHAEOLOGY. An unusual trip, fully escorted. Forum Travel, 2437 Durant, Berkeley, CA 94704 (415) 843-8294

SAIL THE FLORIDA KEYS. Explore, fish, photograph, and study this unique environment. The classic 40-Chesapeake Bay Skipjack Sea Breeze II will take you there, from Elliott Key to Dry Tortugas. Write: Sea Breeze II, 2717 S.W. 31 Ct., Miami, FL 33133

VACATIONS IN NATURAL HISTORY for the single traveler, Blue Sky Adventures, Dept. NHM, Oak Ridge, NJ 07438

WASHINGTON WILDFLOWER SAFARIS to Cascades and Olympics with professional naturalist Brad's Tours, 401 E. Mercer #31D, Seattle, WA 98102

## RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

helped to stigmatize moonshining, making people aware that untaxed liquor is a drain on the commonweal and a peril to health. The antimoonshine literature explains that unscrupulous still operators contaminate their whiskey with toxic lead salts from car radiators used as cheapjack condensers instead of the conventional copper tubing.

To make matters worse, by the end of the sixties, courts were handing out moonshining convictions routinely and Treasury men found they could uncover many stills simply by monitoring suspiciously large sales of sugar. Indeed, sugar had become so basic to moonshining that the zoom in world sugar prices, which sent sweet tooths everywhere into a panic, had a lethal effect on marginal moonshiners. Old-timers who had kept working at their stills for lack of another vocation could no longer compete with cheap, legal whiskey. The high cost of sugar had priced them out of the market. These grizzled, folkloric bootleggers did not, by and large, return to moonshining, and few younger men moved in to replace them.

One retired moonshiner, Arthur ("Bad Eye") Williams remembers when he handled 500 cases of illegal whiskey in a week, fetching it from country stills and running it into Richmond, Virginia, where bootleggers like him used to congregate at an all-night restaurant in the Central Market and swap stories about fast chases with revenuers. His last arrest was in 1967, and after five years in federal prison, he finally went straight. Williams, half of his face disfigured from a booby trap that went off when he tried to steal a cache of moonshine as a boy, now finds the whiskey business too well policed, too risky. He hopes to make use of his special skills in a new, legit venture, a gasohol distillery.

Not every moonshiner in America has retired into nostalgia and law-abiding capitalism. Nearly everyone I have talked to in the southeastern mountain area claims to have a source for white lightning, usually a backwoods practitioner operating on a small scale. In most cases, however, these anachronistic mini-distilleries play as insignificant a part in the overall picture of American liquor production as, say, the homespun wool turned out by individual hobbyists around the country does in the total output of yarn in the United States. But in a handful of rural counties, "homemade" liquor is big business, highly organized and on an industrial scale.

Franklin County, Virginia, just east of the Blue Ridge, is by far the leading center of untaxed whiskey production in the land. Not long ago, the crusading Franklin *News-Post* established this fact in a carefully documented front-page story headlined: "FRANKLIN NO. 1 MOONSHINE COUNTY. No other area even close." The paper's editor-publisher, Kermit W. Salyer, who has been battling local moonshine interests for years, printed official statistics showing that during a two-year period in the late seventies, authorities seized 165 stills in the county with a mash capacity of 125,000 gallons. One still, destroyed by lawmen in 1972 at a site disguised as a cemetery, had a mammoth

Mike Wray

*In January 1980, Treasury agents blew up a still in Franklin County, Virginia.*

16,000-gallon capacity. Since it typically takes only five days to complete a "run" of a single batch of mash, that one site could have produced about 1.2 million gallons a year. With so much at stake, it is no wonder that the still owners do what they can to protect their investment.

Salyer contends that the whiskey interests in Franklin County have tried to put him out of business by setting up a rival newspaper, which siphons off advertising and circulation that might otherwise go to the *News-Post*. Salyer has, nevertheless, managed to keep his paper afloat and to spread the word about his county's dirty little secret. Because of his statistical exposé, published in late 1979, the U.S. Treasury Department and the Virginia Department of Alcoholic Beverage Control staged a raid on stills in Franklin County in January 1980. The national media were invited to bear witness. Salyer, in an editorial, dismissed the raid as a publicity stunt and called for more money to be spent on routine enforcement. He had a point.

Certainly, it did not require national television coverage and a feature in the *New York Times* to reveal what had been common knowledge. Local authorities do not try to conceal or deny the prevalence of moonshining. The casual visitor to the county administrator's office cannot fail to notice that the painting on the wall behind the receptionist's desk is titled *Franklin County Steamer*. It is an attractive picture of a classic still.

When I passed through Franklin County recently, no raids were in progress and I was unable to taste any of the locally celebrated, homemade fruit brandies. But I was invited to try samples of local white lightning by W. Q. Overton, the sheriff, who presides over Franklin County's grim stone jail. There, in a locked closet, which serves as the county's evidence vault, were secreted three nondescript bottles of homegrown hooch. Two of them contained whiskey that was powerfully alcoholic, clear as water, reasonably smooth tasting, almost as refined as commercial vodka. The third was more classic and had the sour taste that aficionados of moonshine prefer. This sourness is caused by a complex of chemicals that "puke" out of the still at the beginning of a run. At legal distilleries, these "sour heads" are drawn off and thrown away. Moonshiners, however, intent on maximizing production, often leave them in. The resultant taste is roughly similar to the characteristic flavor of tequila or those French and Italian spirits distilled from the dregs of wine making, which are known as *marc* and *grappa*, respectively. I mean this comparison only as a rough approximation. It would take a serious chemical analysis of these quite different drinks to establish which of the dozens of possible chemicals lay behind the special taste of each one, but there is definitely a family resemblance. And that has social as well as technical importance. The French, the Italians, and the Mexicans have continued to drink vigorous alcoholic beverages derived from a rural tradition of home distillation. Only in America have we shunned our ancestral liquor, abandoning it almost completely to criminal producers and a shrinking clientele at the fringes of mainstream American life.

---

**Mint Julep**

- 1 tablespoon sugar
- 1 tablespoon chopped mint leaves
- Shaved or crushed ice
- 2 ounces bourbon
- 1 small bunch fresh mint
- 2 drinking straws, cut short

1. Put sugar and crushed mint in a mixing bowl. Crush to a paste with the back of a wooden spoon.
2. Add a tablespoon of water to the mint-sugar paste and stir to produce a green syrup.
3. Fill a metal cup half full of shaved or crushed ice. (Special julep cups are sold for this purpose, but any silver cup will do. In fact, an ordinary tall glass will suffice, but will not, of course, frost in the same dramatic fashion as silver.)
4. Pour the green syrup and the bourbon over the ice. Slip in the sprig of mint so that it rises above the ice slightly. Insert the straws.
5. Place the cup on a tray without touching it, to avoid leaving fingermarks. Frost in the refrigerator. This will take thirty minutes to an hour.

Yield: 1 julep

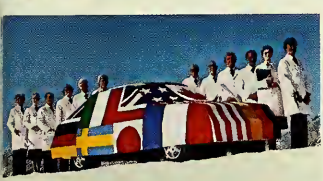
INTRODUCING

# THE NEW WORLD CAR FORD ESCORT



### ENGINEERING TEAMS FROM AMERICA AND OVERSEAS JOIN FORCES TO CREATE A NEW CAR WITH BETTER IDEAS FROM AROUND THE WORLD

Top engineers drawn from the worldwide resources of Ford Motor Company teamed up to create Escort. They pooled their expertise...compared, tested, evaluated, experimented—to come up with better ideas.

The result: a high-mileage car built in America to take on the world. Escort will be made in America for American drivers...with other models built and sold overseas.

### HIGH MILEAGE THROUGH ADVANCED TECHNOLOGY

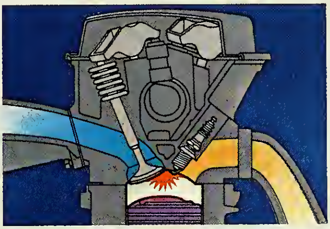
Escort has higher gas mileage ratings than subcompacts such as VW Rabbit, Honda Accord, Toyota Corolla hatchback—yet Escort has more room—in fact, Escort has the room of a compact (based on EPA Volume Index).

**30** EPA EST MPG* **44** EST HWY*

*Applicable only to sedans without power steering or A/C. For comparison. Your mileage may differ depending on speed, distance, weather. Actual hwy mileage and Calif. ratings lower. Excludes diesels.

### ONE OF THE MOST POWER-EFFICIENT ENGINES AVAILABLE IN AMERICA

Escort's new-design compound valve hemispherical head (CVH) engine gives you high mileage plus power for freeway driving.



### FRONT-WHEEL DRIVE AND FOUR-WHEEL INDEPENDENT SUSPENSION

Escort comes with front-wheel drive...four-wheel fully independent suspension...rack-and-pinion steering...stabilizer bar...new all-season steel-belted radials, and other road-control features.

### DRIVE A WORLD CAR

Whether you buy or lease, see your Ford Dealer now to order your Escort...3-door Hatchback, 4-door Liftgate...or even a Squire wagon option. And remember to ask about Ford's Extended Service Plan.

Escort Liftgate...4-doors and wagon room when you need it.

## BUILT TO TAKE ON THE WORLD

Canon
A-1
LENS MADE IN JAPAN
CANON LENS FD 50mm 1:1.8

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.
